A fundamental question affecting the entire problem is this: Is it possible to make a machine serve to effect the electrical connection of any line, in a large or small group, with any other line in the group, for the purpose of telephone communication, and afterwards to effect a disconnection when required? There can be, even at the present early stage of development, but one answer to the question. That it is. The automatic switchboard at Grand Rapids, Mich., recently selected for me 100 different lines chosen at random from among approximately 5,000 lines centering in that office. Some of the subscribers called did not respond, which will occur in any system, and some of the lines were automatically reported busy, which is to be expected; but in no single case was the wrong line chosen, and in but one case was the disconnection improperly secured. The verdict of a large number of the subscribers interviewed by me in that city is practically unanimous to the effect that they uniformly secure their connections and disconnections promptly, accurately and satisfactorily.

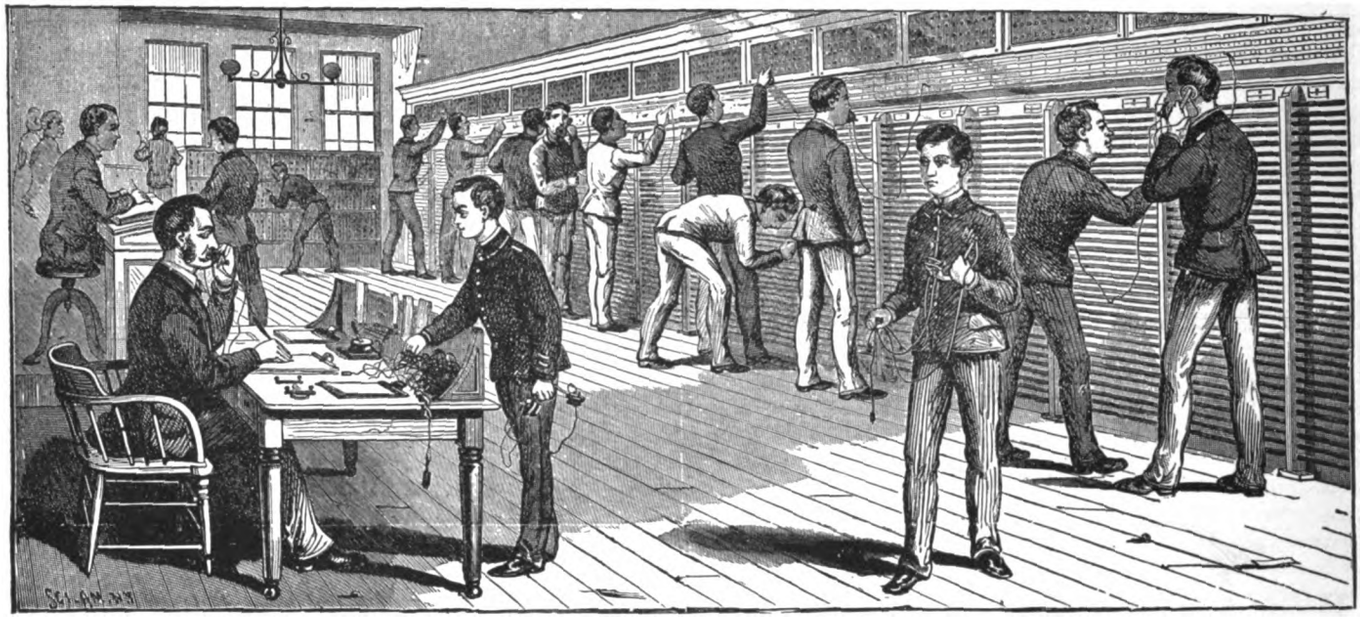
I conclude, then, in view of the present achievement, and of that future progress which this must stimulate men to make, that it is possible for the automatic switch to perform these functions satisfactorily.

If, then, the automatic switchboard may be made to accomplish the commonplace connection and disconnection of lines which form the great bulk of the work in a telephone exchange, is not the system so inflexible in its method of operation as to preclude the possibility of its performing the great multitude of special duties which, while not constituting the main bulk of the work, are nevertheless of constant occurrence and of hardly less importance? I refer to such matters as toll connections, private branch exchange work, and to a number of less important but nevertheless necessary classes of service.

A prominent telephone engineer has recently remarked to the effect that if some of the people enthusiastic on the subject of automatic switching in telephone exchanges were to visit the school for telephone operators maintained by the New York Telephone Company, they would be discouraged in their efforts, as no machine could ever be made to perform the many and varied functions that it was necessary to teach these young ladies before they became proficient telephone operators. This seems to be a statement that has very little to do with the real automatic problem. It should never be required that the machine shall do the same work that is required of the girl, nor do it in the same way. That is manifestly impossible, for no machine can ever be endowed with intelligence. (It may be that you will say that there are some telephone girls similary affected.) Since the very reason for the existence of the automatic exchange is to do away largely with the operator, it follows logically that whatever intelligence is to be applied to the making of the ordinary connection between two lines shall be that with which the subscriber desiring to make the connection is endowed. Here is a fundamental difference between the two systems, which must always lead to different modes of operation.

The real functions that the automatic switchboard should be required to do automatically, are those relating to the ordinary routine work of connecting and disconnecting subscribers' lines under the control of the calling subscriber. When some act needing intelligence at the central office is required, then let an operator supplement the work of the machine. To condemn

Digitized by Google



The Old Law Board at St. Louis, One of the Earliest Types of Switchboards.

the automatic switch because it will not perform all of the special requirements without the aid of human intelligence, is just as unfair as to condemn as valueless a Linotype machine because it cannot digest one of Steinmetz's equations. My mind has gradually changed upon this point until the doubt now exists as to whether the automatic system, widely supplemented by operators, is not even more flexible than the manual. It is the ease with which the personality of the operator may be introduced into the automatic system as a whole, and also the ease with which certain of the purely automatic functions may be varied by mere changes in the circuit, or in the mechanical relation of the parts, that makes this doubt exist.

Of course, there are many problems concerning traffic and service that are yet to be worked out for the automatic system, but apparently the longer one studies the automatic problem, the more nearly he becomes convinced that the automatic system is sufficiently flexible, with the interjection of human intelligence when necessary, to make possible the solution of practically all of the problems of service.

So far as I am aware, the selective signal party line working has never been accomplished commercially with automatic systems. I believe that the reason for this is solely the fact that automatic telephony is yet new. I have recently seen a plan whereby any ordinary number of stations can be selectively operated on a party line with practically no other added complication either at the central office or at the subscribers' stations than that which is added to the apparatus of an individual line manual system to adapt it to the same class of party line work. The solution of the automatic party line problem, while not yet reached to the extent of being actually introduced into commercial use, is entirely possible and the party line matter will not be one of the controlling factors in the solution of the problem: Automatic vs. manual.

Having seen that the thing is possible, that it seems from a technical standpoint to be able to do what is wanted, another question is: Do the subscribers like it?

The evidence all seems to point in one direction. They do. At Grand Rapids, Mich., ninety-five per cent. of a large number of subscribers interviewed by me liked it better than common battery manual service; four per cent. did not care much one way or the other, and one per cent. liked the manual system better. At Fall River, Mass., where the system has been in use for a much longer period, the verdict was quite the same in effect. Evidence from other cities where automatic service is being tried seems to agree. It must be said in fairness, however, that at Grand Rapids the mass of subscribers is leavened by the presence of a large number of stockholders in the local company. Again, there is in that city much civic pride in the system. Telephone people come from all parts of the country to inspect the plant. Still again, the delight of the subscribers may be similar to that of a child with a new toy, but this can hardly be true, because of the fact that the exchange at Grand Rapids has been in service for a period of nearly nine months, and is carrying a very large business load, so that if the people were not actually getting satisfaction they would possibly know it. The new toy idea is apparently disproven by the condition at Fall River and New Bedford, where the service has been maintained for several years, and seems to be much liked.

The question also naturally arises: Is not the automatic switchboard and necessary subscribers' mechanism too complex to be maintained in proper working order without undue cost? It is perhaps too early to decide this question. There is not enough evidence one way or the other. Judging from the past, however, the tendency of the industrial achievement seems to be to do things automatically. As examples, take the arts of printing, of weaving, and the use of automatic machine tools.

Summing up, therefore, the statements already made, the automatic system is not only a possibility, but is actually here. With the interjection of human intelligence to supplement it in performing certain functions, it seems to be as flexible as the manual. Party line, common battery, and measured service working, while not yet achieved commercially, so far as I am aware, seem to be well within the grasp of those who are doing the development work. The public seems to like it, and we do not know whether it is too complex or not.

It will be noted from the foregoing that the idea of having the central office apparatus perform *all* the phases of telephone service is apparently not tenable. Many of those who have advocated it in the past have abandoned it, and are introducing human aid in the performance of some of the functions. This being true, a certain number of operators will be, and are, needed in automatic exchanges. This tends to destroy in some degree the primary object of the automatic system—the doing away with operators. We have seen many papers bearing on each side of this question, to the effect that the salaries of the operators were or were not to be eliminated; that retiring rooms, matrons, operators' luncheons, etc., were or were not to be done away with. These items of expense will probably exist to some degree in all large automatic exchanges. That they will be greatly reduced is without question, but whether or not they are reduced to such an extent as to offset other sources of expense introduced by the employment of automatic apparatus is a problem yet to be solved.

What are some of these sources of expense that tend to offset

Digitized by Google

the reduction in operators' salaries and expenses coincident therewith? Taking the system as a whole, we find that the present automatic system is considerably higher in first cost than the manual system, and assuming that interest and depreciation are at the same rate in each case, this shows to considerable disadvantage against the automatic system in the annual charges due to these items alone.

For an exchange of 5,000 lines served to one office, the cost of automatic equipment, including telephones, may be taken at $35 for each individual line. In manually operated exchanges the corresponding cost is not far from $25 per line. The difference becomes greater—that is, more in favor of manual—for smaller offices, and smaller or less favorable to the manual in larger offices.

Whether or not the depreciation on automatic apparatus should be taken at a higher rate than that on the manual, is a question that we have not at present sufficient data or information to determine. It is true that in the automatic switchboard the flexible cord nuisance found in all present form of manual switchboard apparatus is largely eliminated. It is also true that the automatic apparatus is more complicated, and requires greater care in its maintenance; but whether, if both systems are maintained with reasonable care, the automatic will show a much greater rate of depreciation than the manual I am not at all certain. Much of the depreciation in manual telephone apparatus is due not to the fact that the apparatus wears out, but rather to the fact that the apparatus is rendered obsolete by new inventions. That the same will be true in the case of automatic apparatus cannot be doubted, but it is a good point to bear in mind that if telephonic development should point toward automatic apparatus to the exclusion of manual, and should prove the superiority of automatic, then the highest developed and newest manual apparatus will depreciate greatly in value by that fact alone. It does not seem unreasonable, therefore, to place the rate of depreciation on both manual and automatic apparatus at about the same figure.

In point of maintenance the advantage must be conceded to the manual. This is certainly true at present with regard to both the central office and the subscribers' station apparatus. No good reason is apparent why it should not always be true. Automatic apparatus is especially at a disadvantage at the subscribers' stations, and it is really at this point that the automatic system seems to involve a poor engineering feature. The tendency of telephone development in regard to substation apparatus has been until lately along what seemed to be unquestionably good engineering lines. The substation apparatus has been gradually simplified, the battery has been removed, as has also the magneto generator, and the instrument has been reduced to the simplest fundamental parts.

Automatic telephony as at present developed for large work takes a step backwards by reintroducing the local battery. That this is disadvantageous no one can deny, but on the other hand it must be pointed out that the disadvantage is by no means as great as it would have been several years ago because of the fact that dry batteries have recently come into almost universal use for this kind of work and are far superior, all things considered, to anything heretofore available.

The disadvantage of local batteries, while mitigated, is still present, and is real; but, taking the automatic system, as we have reason to believe it will exist in the future, with no local batteries, it will still possess, as far as we are able to see, a more or less complicated impulse transmitting device, by means of which the subscriber will be able to direct the movements of the switches at the central office. Complexity not only of mechanism, but of function, is thus introduced at the subscriber's instrument, and this seems to be an inherent disadvantage to all present schemes of automatic exchange working. This, of course, is another factor that must be weighed in considering the relative economies of the two proposed methods.

There is a point that I have not yet seen mentioned in print which, under certain cases, seems to be of great importance. This is the matter of trunking between two or more automatic offices in such cities or communities as naturally demand, by the distribution of their subscribers, more than one office. It is true that the present automatic switchboard seems to be capable of properly handling this condition if the requisite number of trunk lines between the offices are provided. At first thought it seems that the number of trunks required between offices for a given amount of traffic might be somewhat less in the case of the automatic than in the case of the manual system, on account of the immediate disconnection and release of the trunks, in the automatic, upon the hanging up of the receiver of the calling subscriber. Further consideration, however, will show that there is very little difference in the time the trunk is held busy in the two systems, the length of actual conversation being assumed to be the same in each case. The reason for this is that, while the automatic gains in this respect in the release, it loses something in the making of the connection, because in the case of the automatic, the trunk is selected with the first movement of the dial by the subscriber, and the length of time that the trunk is held busy, therefore, must include the time during which the subscriber is setting up his own connection; whereas, in manual boards, a trunk line begins to be busy at the time when the *B* operator picks up the incoming trunk plug and designates its number to the *A* operator.

So far there seems to be little difference between the systems in this respect.

The bearing on the trunking problems of the relative efficiencies of different sized groups of trunks between offices does not, however, seem to have been considered by many in considering the question of automatic vs. manual exchanges. When sufficient trunks are provided between offices to handle business on the so-called "no delay" basis, it is known that a large group of trunks will handle very much more business per trunk line than a small group. For instance, when there are only ten trunks in a group between offices, it is a well-established fact that slightly less than eighty calls per trunk per day may be handled. If, however, the group is increased to 100 trunks, as many as 145 calls per trunk per day may be handled. This is an increase of considerably over eighty per cent. in actual trunk efficiency. In the present automatic system, group the trunks as you may, it is inherently true that the efficiency of trunks is reduced to that of a group of ten. I do not mean by this that it is not possible to place as many trunks as desired between any two offices, but that any subscriber has access to ten trunks only in order to secure a connection to any other office. It is true that some other subscriber may have access to another ten, or to the same ten, but no one subscriber can reach more than ten. This seems to be a grave objection to the use of automatic systems as at present developed, in those communities where several offices must be employed and where traffic is such as to demand a large number of trunks between offices. The remedy to this is obviously that of giving the subscriber the chance to select his trunks from larger groups. This, I take it, is one of the problems that need serious consideration in adapting the automatic system to very large communities. It does not enter seriously in single office work.

In all that I have said I have attempted to take the very practical view of the engineer, and fundamentally that view must always compare systems with the intent of selecting a means of doing what is required well enough for the smallest price. From the strictly engineering view one does not take into account relative popularities of mere ways of accomplishing results. But this is necessary in such a case as this, for there are features of the automatic system which may make it so popular as to force upon the owners or prospective owners of telephone industries a serious consideration of the doctrine of expediency. This is by no means the least of the important things to consider.

I expect to be criticized because I have not solved the problem. It cannot now be solved any more than the question of alternating versus direct-current transmission could be decided when we first were brought to realize that there was an alternating versus direct-current transmission problem. My object has been to state the problem as I see it, and I hope that in doing this something may have been accomplished toward clarifying it.

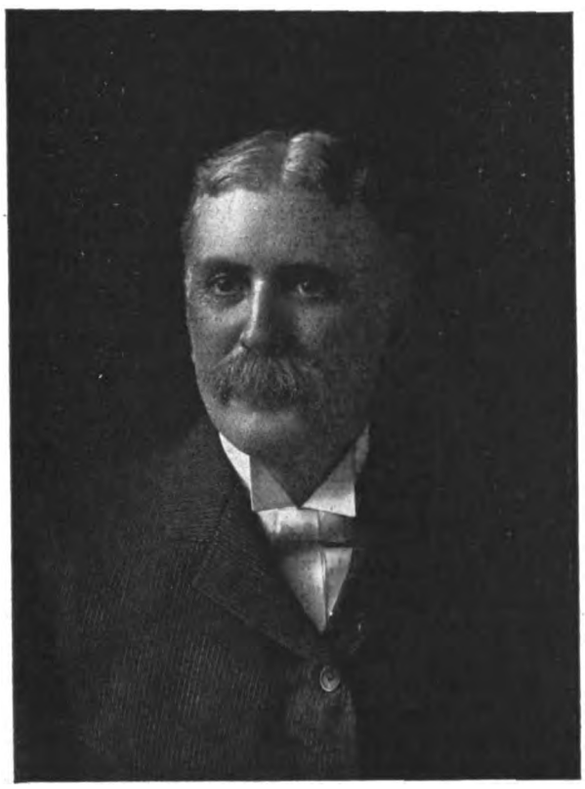
IN THE OPERATING FIELD.

THE NATIONAL INDEPENDENT TELEPHONE CONVENTION.

THE National Independent Telephone Association will hold its annual convention at St. Louis on September 21, 22, 23, and 24. The headquarters will be at the Inside Inn, situated on the World's Fair grounds. Addresses will be made by men of national reputation, and special entertainment features



Hugh J. Doherty, President of the National Telephone Association.

have been arranged for the pleasure of the delegates and their friends. Reduced rates on all railroads have been secured so as to allow of as large a number of Independent telephone men to attend as possible.

BELL TACTICS AT LOGANSPORT.

THE people of Logansport, Ind., are experiencing many similar tactics to those employed by the Bell at Evansville. A franchise ordinance has been prepared by the Bell company to be submitted to the common council, but so far no definite details of its purpose have been made public. Councilmen have been approached and urged to support it, and the usual tactics with regard to lobbying have been worked vigorously. It was expected that the franchise would be submitted at the last meeting, but evidently the Bell company was afraid of the moral effect the large attendance would have had upon the councilmen, and it was side-tracked till the next meeting. Those of the councilmen who have been approached state that the franchise is a very broad one. The city records show that a well-guarded long-distance franchise was granted to the Bell company some time ago, but it was refused. Now the matter is to come before the council with the intention that the restrictions to long-distance business be stricken out and local rights granted.

The strange feature is that the Bell people who deserve the franchise do not come out in the open, so that the public can see what it is and what it means, but in keeping with its usual methods, it hopes to gain its point by stealth. In this instance the public will be on hand to see that the ordinance is not railroaded through the council.

CONVENTION OF MUNICIPAL ELECTRICIANS.

THE ninth annual convention of the International Association of Municipal Electricians was held at the Grand View Fraternal Hotel, St. Louis, this week. The opening session was held at 9.30 A. M., Tuesday, September 13th, in the meeting room of the hotel. The following papers were announced for discussion: "Method of Testing," by Walter M. Petty, of Rutherfor, N. J.; "Street Lighting," by A. S. Hatch, of Detroit, Mich.; and "The Limitations of the Telephone for Fire Alarm Purposes," by Adam Bosch, of Newark, N. J.

MEETINGS OF DISTRICTS NOS. 7 AND 9, OHIO INDEPENDENT TELEPHONE ASSOCIATION.

AT the meeting of the Seventh District of the Ohio Independent Telephone Association, held at Lima, on the eighteenth of August, twenty-four cities and towns of the district were represented and representatives of the State Association were also present. The district comprises the counties of Marion, Wyandot, Hancock, Putnam, Paulding, Van Wert, Mercer, Allen Auglaize and Hardin. George H. Metheney, of Lima, was elected president, and D. A. Clark, of St. Marys, secretary. An executive committee, consisting of one member from each county in the district, was also appointed.

F. L. Beam, of Columbus, president of the State Association, was present and stated the objects of the association to be for the mutual protection and general advancement of the interests of the Independent telephone business of the State. Mr. J. B. Hoge, vice-president of the United States Telephone Company, was present and gave some interesting and valuable information concerning the relative Bell and Independent interests in the State from a physical standpoint, comparing the wonderful growth and development of the Independent movement, with the doless and almost inactive policy of the Bell. Mr. M. B. Overly, general manager of the United States, also spoke on the same lines and promised still better service from his company.

The meeting was a very successful one, and the general feeling was that a strong State and district organization should be perfected and the Independent interests placed on a firmer and more aggressive basis than ever.

District No. 9 held its first meeting at Columbus on August 23. This district embraces twelve of the most important counties in the State and an effort was made to interest persons financially interested in the telephone business as well as the managers. The effort was successful beyond expectation, and was attended by representative banking, professional and business men of the several counties in the district. The utmost enthusiasm prevailed, and the plan of organization proposed met with unqualified indorsement and acceptance.

The plan as accepted involves the appointment of an auxiliary committee, appointed by the vice-president of the district, made

PROCEEDINGS OF THE INTERNATIONAL ELECTRICAL CONGRESS AT THE WORLD'S FAIR, ST. LOUIS.

At the International Electrical Congress, held at St. Louis this week, there were gathered together delegates representing every branch of electrical industry from Great Britain, Italy, France, Germany, Spain, Sweden, Norway, Brazil, Argentine Republic, South Africa, Australia, the United States, and several other countries. At the opening session the nominations of the organization committee for officers were ratified. Professor Elihu Thompson, past president of the American Institute of Electrical Engineers, was chosen president of the body. Dr. A. E. Kennelly, of Harvard University, was elected general secretary, and W. D. Weaver, of New York, treasurer. The vice-presidents include Prof. H. S. Carsart, of Ann Arbor, Mich.; C. F. Scott, of Pittsburg, and Prof. S. W. Stratton, of the United States Bureau of Standards. Honorary vice-presidents were elected as follouss Prof. Moise Ascoli, Italy; Col. R. E. Crompton and Dr. Glazebrook, England; Antonio Gonzales, Spain; R. Kaye Gray, president of the British Institute of Electrical Engineers; Prof. L. Lombardt, Italy; Prof. John Perry, England, and Prof. Henri Poincare, France.

After routine business had been carried out President Elihu Thompson delivered a short address welcoming the foreign delegates to the United States.

The allotment of the delegates to their respective sections was then carried out, after which the general session adjourned to meet again Saturday morning for the closing exercises.

The section on "Electrical Communications" was presided over by Mr. F. W. Jones, of New York, with Mr. B. Gherardi, of Brooklyn, as secretary. This section covered all matters on telephone and telegraphy. In this issue part of the papers presented in this section are published. The other papers in this section of interest to the telephone industry will be printed in our issue of next week.

up of active persons in each of the twelve counties, to act in conjunction with the vice-president and to secure accurate and reliable data as to the situation telephonically in each county.

Telephone companies controlling over 27,650 telephones and representing an investment of $3,530,000 were represented, and the substantial result of the meeting was to bring these different companies into more intimate relations, to provide plans, the result of which will be unanimity of action on their part and the establishment in a pratical and businesslike way of an actual community of interest among them.

The meeting was presided over by the undersigned and interesting addresses were made by the Hon. Cyrus Huling, president of the Columbus Savings & Trust Company; J. C. Reber, cashier of the Winters National Bank, of Dayton; Frank L. Beam, president of the Ohio Independent Telephone Association, and by many other persons of equal prominence.

The names of the members of the auxiliary committee, above mentioned, and the counties from which appointed, are as follows: The Hon. L. P. Ohliger and J. R. Zimmerman, for Wayne County; the Hon. George Adams and M. M. Heron, for Holmes County; H. C. Devin, Esq., for Knox County; Wm. M. Heseltine, for Delaware County; Howard Schwarz, for Ashland County; S. E. Ward, for Richland; Sol M. Wolf, for Crawford County; W. H. Fledderjohann and F. L. Van Gorden, of Hocking County; Ralph Reamer, for Franklin County; Amai W. Whitney, for Morrow County, and Noah Yenrick, for Fairfield County; Harry P. Sinsher and Chas. E. Hallender, for Licking County.

AN OPEN LETTER TO THE PEOPLE OF PEKIN, ILL.

THE management of the Home Telephone Company of Pekin, Ill., has issued an open letter to the general public setting forth the advantages of the Independent system. In part it is as follows:

"A Pekin company for Pekin people—get this fact clearly in your mind. This is a Pekin corporation. Its stockholders are your friends and acquaintances. Its bonds are held by your own friends, and its officers and employees are your neighbors. If it pays money for interest, or wages, or profits, that money, every dollar of it, stays here to be used again and again to the direct benefit of our own city. Is not your loyalty due in a peculiar way to an institution such as this when brought into competition with a corporation founded in Boston, owned in Boston and managed wholly for the benefit of Boston? Our new directory will be ready for distribution September 1, 1904.

"Remember that by January 1, 1905, we will be connected with the Independent telephone exchange at Peoria, with more than 3,000 subscribers. Your own city, with more than 960 subscribers, ought to be a guarantee of the efficiency of our service.

"Why have a telephone in an exchange with less than 200 city subscribers when you can get one for less money in an exchange with more than 900?"

PEORIA INDEPENDENT COMPANY HAS NOT SOLD OUT TO THE BELL.

A RECENT newspaper report from Peoria, Ill., stating that the Independent company had sold out to the Bell, is entirely without foundation. The Independent company has a costly underground system there, and recently the Bell people in laying conduit crossed the former in several places. Bids for the new exchange of the Independent company were recently all rejected because of some insufficiency in the plans. These facts may have given rise to the story.

PICNIC OF STROMBERG-CARLSON EMPLOYEES.

THE first annual picnic of the employees of the Stromberg-Carlson Telephone Manufacturing Company, of Rochester, N. Y., was recently held at Sea Breeze. Nearly 1,000 of the employees of this large industry participated.

Preparations for the event were in the hands of capable committees and when the picnickers arrived at the lakeside they found entertainment mapped out for them from the start.

At 10.30 A. M. there was a ball game between married men, captained by Mr. Chamberlain, and single men, captained by Mr. Rice.

During the afternoon athletic games were held and also dancing, and a cake-walk in the evening.

The cars which conveyed the picknickers to the lake were decorated with streamers. Myers's band furnished music. Coffee and lemonade were served at the pavilion and dinner was served at the hotels.

Following are the committees that were in charge of the outing:

Committee chairmen—Advertising, W. Radford; athletics, W. M. Angle; badges, Miss Dillon; prizes, W. Peachy; transportation, H. L. Rice; refreshments, C. A. Hughes; press, Charles C. Bates, dancing, J. T. McGuire.

Executive—P. V. Mahon, T. Tanswell, S. Kendall, B. Mouatt, N. O. Tassell, W. E. Russell.

Finance—W. W. Hawkins, W. Frisbie, A. J. Mahon, W. Parker.

Reception—E. H. Satterlee, C. E. Angle, L. B. Somerby, A. Stromberg, A. Carlson, W. W. Hawkins, A. J. Mahon, T. W. Finucane, M. S. Conner, W. J. Frisbie.

Dancing—Mae Cooney, May Maddocks, Julia McCall, Gerald Cox, Louise Schrieber, Sherman Thomas, Martin Gagie.

Refreshments—J. Finkle, Martin Gagie, M. J. Guinan.

TELEGRAPHY AND TELEPHONY IN JAPAN

Paper Presented at The International Electrical Congress at St. Louis.

By Saitaro Oi.

電報 話筒

TELEGRAPHY, as in all other countries, is also the oldest and was the first practical application of electricity in Japan. It is generally believed that Commodore Perry of the United States, when he came over to Japan in 1854, brought two sets of telegraph instruments with him and presented them to the Shogun (at that time the Lieutenant General, or Governor General, of the Empire). The first telegraph line, however, was constructed between Tokyo and Yokohama in 1869, the instruments used being Bréguet's instruments, which were employed for some time until all were superseded by Morse inkwriters. There was not very much progress until 1877, when the civil war broke out in the southern districts; this naturally necessitated an increased use of the telegraph and the lines were extended to the important places of the Empire. These 36 years from 1869 to 1904, have wrought a remarkable change in our social conditions in general, and in the domain of means of communications for the public some progress has been made.

There are a good many private telegraph and telephone lines worked exclusively for railway and for various other industrial purposes, which, according to the latest report, amount to the remarkable figures shown below:

	Miles of wire.	Number of instruments.
Telegraph	10,892	1,340
Telephone	10,635	5,381

The first telegraph line in this country was constructed by some English engineers and linemen in the service of the Japanese government. The chief engineer was Mr. E. Gilbert, who had been connected with a railway company in Scotland before he came to Japan, and as may be imagined, the method of surveying, construction and maintenance of the land lines laid out by him was naturally after the English practice, and is continued, with more or less changes, down to the present day. The lines are built in a solid manner, so that they can withstand the attacks of storms, which are almost certain to come once or twice in autumn every year.

As to the telephone lines in towns, the method of construction may be said to follow American rather than English practice, and in some places where no cables are employed, as many as 100 to 150 wires are run upon a pole planted along the side of the streets. In large towns, however, these crowded overhead wires are generally being taken down and laid underground, and as will be seen from the table I give later on, there are at present some miles of underground lines.

Poles are generally of cedar, which grows in abundant quantity in different parts of the country. The number of main poles used varies, of course, with the number of wires put up, the nature of the route through which the lines pass, etc.; but in the open country there are, as a rule, from 38 to 26 per mile; and where there are too many wires for one pole to carry, trussed poles—often H poles—are employed. Ordinary main poles are of 22 to 24 feet. Taking the average, 64 per cent. of the main poles are stayed, while 14 per cent. are strutted. Boucherizing is a common practice as a means of preservation of the poles, but lately creosoting is being tried though on a small scale.

Boucherized poles last about 18 years on an average, whilst untreated poles begin to decay within 5 or 6 years; and owing to the fact that the price of timber, which was fabulously cheap in the earlier days of telegraphy, has become somewhat expensive with the recent progress of engineering work in general, various compounds and methods of preserving wood have naturally had the attention of the engineers concerned. Considering, however, the different conditions of this country, the most suitable one for telegraph and telephone purposes seems, so far, to be the boucherizing process. Forty-six per cent. of the poles are boucherized, the remaining untreated.

Arms with double-cup porcelain insulators are exclusively used and are always fixed on that side of the pole facing the so-called up-station. For telegraph lines, two-wire arms of 24 inches and 34 inches are generally used except where many wires are to be run. They are secured to the poles a foot apart, and alternately in case more than two wires have to be put up.

Telephone wires are run on 4, 6 or 8-wire arms most commonly, and long-distance lines on braced 6-wire arms. The distance between the centers of the arms is 1 foot 6 inches, the minimum distance allowed from the ground to the lowest arm being 16 ft. The span of the long-distance lines is usually 48 yards, the minimum transposition being done at every twentieth pole.

For telephone lines in towns where there is not much snow we use No. 17 S.W.G. hard drawn copper wire, and silicon bronze wires, but in the northern districts where snowfall is abundant during the winter, No. 14 iron wire is run for subscriber's line. For the interurban telephone service three gauges of copper wires —No. 8 S.W.G., No. 12 S.W.G. and No. 14 S.W.G.—are employed.

Fig. 1. Telephone line in Japan.

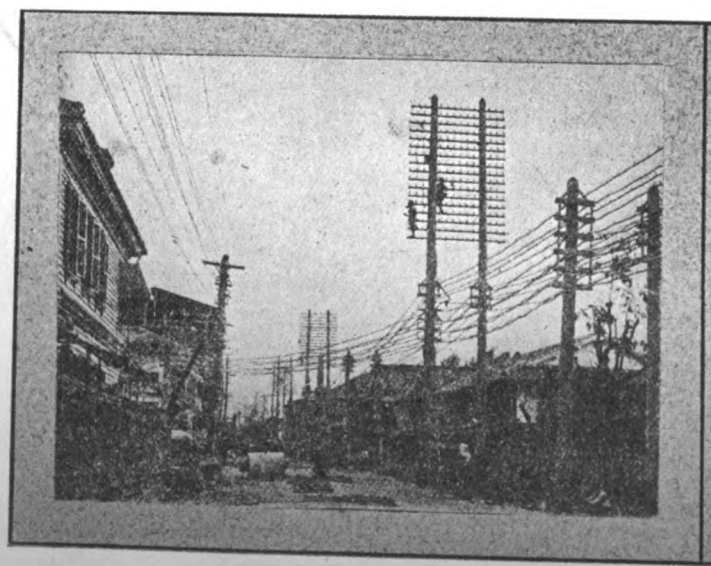

Fig. 2. Street Telephone Booth in Japan.

For long spans such as river crossings, steel is almost always used in the case of telegraph lines, and bimetallic wire for telephone circuits of long distance. We had many long spans when railways were few, but at present we have our telegraph lines at river crossings, attached to rialway bridges, or cables are laid on the girders in a trough. The longest air span now in existence is 800 yards with steel wire, and 320 yards with bimetallic wires, each of 170 lbs. per mile. Fig. 1 is a general view of a telephone line in a town.

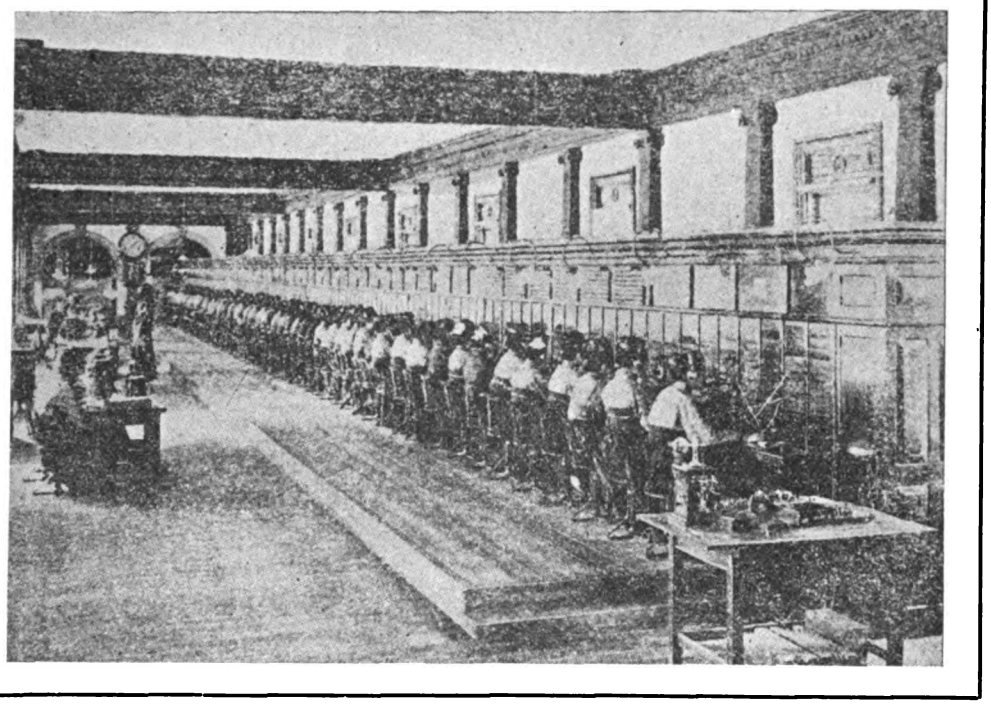

Fig. 3. Exchange at Tokyo.

When the first underground construction was undertaken in Tokyo in 1896, we adopted 3 in. cast-iron pipes and the same system was employed, to a considerable extent, in the other towns also; but my visit to the United States in 1898 gave me a favorable impression as to vitrified clay conduit, and immediately after my return home, I advised the authorities to adopt it where we have more than three ducts. Since then the single-duct vitrified clay conduit has become the standard of underground working, as our manufacturers can make it excellently and cheaply.

The telephone cable for underground work is of the dry-core paper insulation, and in large towns apparatus for sending compressed dry air from 3 to 4 atmospheres into the cable are provided for. This proves very useful in Japan as the cables are all imported, and in case cables should get low in insulation we can easily repair them. 100-pair cable was used when the underground work was commenced, but now, 200-pair cable is very common, No. 20 S.W.G. being the size of the conductors. Smaller wire cable has been suggested for some uses, but it has not yet come into actual use. Most of the lines in towns being overhead, we have naturally a great many aerial cables, both of India rubber and dry-core type, put up on poles to avoid too many telephone wires crowded together, or to cross electric light and power conductors, which are also carried along the streets like the telegraph and the telephone lines.

The telephone was first brought to Japan in 1877 by a mechanic returning home from America, and was a magneto telephone encased in a box. Soon after its introduction, the telephone was put into practical use as an auxiliary to the police service in Osaka and vicinity, a considerable length of lines being built for that purpose. Some of the circuits then constructed were more than 30 miles in length and as many as ten such magneto instruments were connected in series on a single circuit of iron wire. As can be readily understood, conversation was no easy task unless by those who had experience in using the instrument. After the introduction of the carbon microphone the application of the telephone for industrial and commercial purposes began to increase remarkably, and it was in 1883 that the idea of starting telephone exchanges first occurred to the authorities. A company was promoted for carrying on the business and a petition was forwarded to the Government asking for a license to start an exchange and carry on the telephone business in Tokyo. That was in 1884. The question whether it should be carried out as a Government undertaking or entrusted to a private capital remained unsettled until 1889, when it was decided, after deliberation, to undertake the work as a state monopoly.

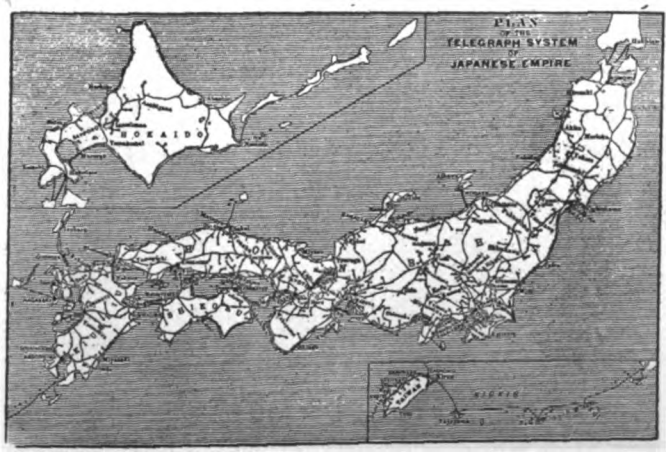

Fig. 4.

While the matter was still in consideration by the Administration, it was thought necessary that our engineers should get more detailed information for the successful working of telephone exchanges. The writer was appointed to make a tour of Europe and America to study telephone matters. My stay in Europe and America lasted a year and a half, and it was in December, 1889, that I returned home from my first trip abroad. At that time an appropriation for the telephone undertaking had already been made, and the work was to be started as soon as possible in Tokyo and Yokohama. The executive office was opened in Tokyo, and letters and circulars were sent out to business men, to the nobility, to Government officials, to manufacturers and, in fact, to any person in the city of more or less prominence. We advertised in the popular papers the opening of telephone exchanges and invited subscriptions from the general public. We did not confine ourselves to letters and circulars or to the newspapers alone, in introducing the telephone to the public, but, in addition, we put up a switchboard and telephones in the building of the Tokyo Chamber of Commerce, and in the Rice and in the Stock Exchanges, and invited people of various occupations to try the instruments in order to be convinced of the practical utility of the telephone. In Yokohama the writer gave a popular lecture to convey to the public an idea of the commercial and

Digitized by Google

social uses of the telephone. In fact, we spared no pains to secure a satisfactory result in the new enterprise, but notwithstanding such efforts on our part, we got only about 70 contracts in Tokyo and 20 in Yokohama when we commenced the construction of the lines. The service was started in Tokyo and Yokohama in December of 1890, the number of subscribers at that time being about 200 in Tokyo and 40 in Yokohama. However, the actual opening of the exchanges and establishment of communication between the subscribers spoke far more eloquently to the public than any letters, newspapers or lectures, and before long our facilities were far behind the demand. The growth of the telephone exchange business since 1890 may be seen from the following table:

GROWTH OF TELEPHONE SERVICE.

Year.	Number of telephone exchanges.	Number of telephone substations.	Miles of subscribers' lines (pole).	Miles of wires.	Miles of overhead cables.	Miles of underground cables.	Nautical miles of submarine cables.	Miles of toll lines.	Miles of toll wires.
1890	2	359	100	669	....	.....	....	22	139
1895	4	2,913	388	4,826	1	.....	....	46	410
1900	25	19,203	1,332	29,287	117	78	4	598	5,309
1903	46	36,700	1,669	40,593	198	173	4	901	7,571

The increase of traffic necessitated putting up more toll circuits, and some 100 miles of new line with about 1,600 miles more wire are now under construction. On completion of the line, Tokyo and Nagasaki, which cities are 800 miles apart, will probably be put in direct communication.

When the exchanges were started in Tokyo and Yokohama, single circuits of No. 18 S.W.G. hard-drawn copper wire were arranged for subscribers' lines, the 100-wire standard switchboards of the Western Electric type and a modified form of the Gower-Bell telephone set with a battery for calling, were employed, the toll lines between the two towns being metallic circuits of No. 12 S.W.G. copper wires. No. 18 copper wires were afterwards changed to No. 17, which is now the standard size of wire for subscribers' lines, except in the northern snowy districts; and the modified Gower-Bell set with calling battery, has been changed to the solid back or Delville set with a magneto.

Small exchanges not having upwards of 600 subscribers are operated with the 100-wire standard switchboard, and for exchanges where more than 600 subscribers are to be connected, multiple switchboards are generally used. At present Tokyo has five exchanges, the largest of which contains 4,000 subscribers and the smallest 1,500, and each exchange is equipped with bridging multiple switchboards. In Osaka there are two exchanges, both of which are also fitted with bridging magneto multiples, having an ultimate capacity of 6,300. Reverse trunking is used between different exchanges in a town and also on short toll lines. Yokohama, Kobe and Nagasaki are also worked with bridging magneto multiples, these towns having only one exchange in each. Kyoto, our ancient capital, was worked with the old series-multiple switchboards, but an alteration to the relay switchboards, manufactured by the Western Electric Co., was effected in May last year, and since then the system is working satisfactorily. Kyoto has no branch exchanges; it has an ultimate capacity of 6,300 and the preesnt equipment 3,000. The series-multiple switchboards are still in use at Nagoya. All other exchanges are being operated with the 100-wire standard switchboards, but some of them experience inconvenience at times in working, due to increase of subscribers, and we anticipate supplying them with multiple switchboards. Fig. 3 shows the interior of the exchange in Tokyo.

A subscriber's set is furnished with either the solid-back or the Delville transmitter and always equipped with an arrester. A desk set, artistically designed, is liked by some people and supplied, if required, upon an extra payment of 6 yen per annum. Where the C. B. system is employed, the same type as the post-office wall set is in use, the transmitter being the solid back. Fuller's bichromate battery for the solid back, and the Leclanché for the Delville are generally used.

The automatic telephone, which has come into use since 1899 is somewhat like the Grey instrument, and so constructed that the operator is enabled to distinguish the kinds of coin put into the slot by hearing different sounds made by the coin in its sliding down along each chute. Fig. 2 shows a view of an automatic call box in the street of Tokyo.

No party lines are in existence at present, except a few telephone call office circuits in small villages. This system, however, has been often considered, with a view to meeting the pressing demand of the public for the telephone, but so far it has not come into use.

The actual number of toll line circuits amounts to about 100. In addition to that number 22 telephone circuits are formed by utilizing the telegraph lines for simultaneous transmission, and 20 by duplex telephony or virtual circuit. Simultaneous transmission of telegraph and telephone was first experimented in 1884 after the Van Rysselberghe system between Tokyo and Yokohama, but the experiment was not made with sufficient care and it ended in failure. The second experiment was conducted rather more carefully in 1886 by using the telegraph wires crossed and it resulted in a success.

In order to give an idea of the present situation of our telephone exchanges, I give the following figures for the seven towns where the exchanges are worked with multiple switchboards:

MULTIPLE SWITCHBOARD EXCHANGES.

Name of town.	Number of subscribers.	Number of subscribers not yet connected.	Public call offices. Ordinary.	Public call offices. Automatic.	Population.
Tokyo	14,192	8,019	46	68	1,640,000
Osaka	6,481	3,608	28	10	930,000
Kyoto	2,413	3,303	13	9	380,000
Yokohama	1,464	517	22	14	300,000
Kobe	1,437	1,152	16	9	260,000
Nagoya	1,327	1,023	7	6	270,000
Nagasaki	742	359	4	1	140,000

When the telephone exchanges were started in Tokyo and Yokohama in 1890, all the lines connecting the two towns were specially constructed with copper wire transposed at intervals as a precaution against disturbance from external causes, and there did not exist much necessity to have recourse to the telegraph lines. In 1894 duplex telephone circuits were tried between Osaka and Kobe, which are 23 miles apart, and were worked quite successfully. In order to actuate the indicators on the duplex circuit, the neutral points of the repeating coils were earthed, and by using the circuit so formed by earthing, direct signal current was sent so as not to cause disturbance to the conversation. The telephone lines between Tokyo and Osaka were opened to the public use in 1896. Combining these lines, which are 377 miles in length, duplex telephony was successfully applied.

In course of time telephone exchanges were gradually opened in various provincial towns, which has enhanced the popularity of the telephone to a great extent and petitions for telephone facilities came in to the hands of the authorities from various quarters. This brought up the necessity of opening telephone call offices first in those places which did not possess telephones, and to save money, existing telegraph lines were used. At present some 1,000 miles of telegraph wires are worked simultaneously for the telephone. Fig. 4 shows the toll line system in Japan at the present moment.

The flat rate system is adopted in all towns. The charges are as follows:

Tokyo and Osaka.....66 yen per annum.
Yokohama, Kobe, Kyoto, and Nagoya..54 yen per annum.
Other smaller towns.....48 yen per annum.

These are for subscribers located within the town limits. Those living in the vicinity beyond the town limits, but within a certain telephone area specified by the government, can be connected to the exchange by a payment of 10 yen per 120 yards or under, for construction of a line beyond the city limits; and a payment of 2 yen per annum per 120 yards or under beyond the city limits as additional subscription.

Digitized by Google

Interurban lines are charged for according to the distance and for a conversation not exceeding 5 minutes. The basis of the toll rate is approximately as follows:

Up to 5 ri (one ri is nearly 2.5 miles)	20 sen.
Up to 25 ri	25 sen.
For each ri beyond 25 ri	1 sen.

In a small provincial town or in a village specified by the government, and which is connected by a toll line to any other town having an exchange, people can be connected at their own expense to the post-office of the specified town or village in order to make use of the toll line from their house.

Small switchboards are provided and worked in such post-offices by the Government, and the subscribers have to pay to the Government 24 yen per annum for the service as well as for expenses for the maintenance of the line, the instrument, etc., which by the agreement must be entrusted to the Government. Seventeen such special exchanges are now working.

The financial condition of the telephone undertaking is a satisfactory one as shown by the following table:

TELEPHONE FINANCIAL STATISTICS.

Year.	Expenditures in yen.	Receipts in yen.	Capital in yen.
1895	91,548	142,616	.....
1900	964,899	1,533,417	.....
1903	1,230,592	2,670,631	12,618,658

The work is partly suspended for the present, owing to outbreak of the war, but when the peace is restored and commercial activity is resumed, it will, no doubt, be continued to meet the public requirements.

LOADED TELEPHONE LINES IN PRACTICE

Paper Presented at The International Electrical Congress at St. Louis.

By Dr. Hammond Vinton Hayes.

THE mathematical discussion of the theory of loaded telephone lines has been fully given in the writings of Prof. M. I. Pupin 1 and Dr. G. A. Campbell.2 In the present paper it is intended to state briefly the results which have been obtained by the use of loading coils on many of the telephone circuits of the Bell companies.

In every problem affecting the transmission of telephone waves over a line, there are two factors to be considered—the attenuation and the distortion of the waves. The loss of energy of the waves upon the line must be kept at a minimum and the several component waves of the telephone or voice waves must be transmitted without unequal relative impairment.

DISTORTION.

The introduction of lumped inductance in the form of loading coils upon a telephone line tends to increase the distortion by the possible unequal reflection of the component waves of different periodicities, and by the possible unequal attenuation of the several waves in passing through the coils.

REFLECTION LOSSES.

The mathematical work of both Pupin and Campbell showed conclusively that if several loading coils lay within a wave length on any particular loaded circuit, and the coils themselves were theoretically perfect, the circuit was distortionless. The spacing of the coils upon a circuit in practice, therefore, depends simply upon a determination of the highest periodicity that should be retained in the telephone waves in order to maintain the character of the voice waves unimpaired. It has been found convenient in studying the spacing of loading coils to consider the number of coils which would be passed by a wave front on each particular circuit in the unit of time, or a second. As the velocity of all waves upon a given circuit is the same, and as the wave length for any periodicity can be readily determined from the velocity, this convention makes it possible to readily determine the number of coils lying within any particular wave length.

A large number of long telephone circuits have been equipped with loading coils, the spacing of the coils upon the several circuits being such as to produce a range of the number of coils per second between 13,000 and 7000. A comparison of the transmission over these several circuits has shown that the quality of transmission is not appreciably impaired even with the lower number of coils per second. This seems to indicate the lack of importance of the overtones of very high periodicity in the successful transmission of speech.

It can be said, therefore, with considerable certainty that the distortion due to reflection losses in a loaded telephone circuit can be neglected, provided the coils are so spaced upon the line as to give at least 7000 coils per second, and that this spacing of the coils is substantially uniform throughout the line.

DISTORTION IN COIL.

To entirely eliminate distortion in a loading coil, it is necessary to have it so designed that the effective resistance of the coil to all the essential periodicities of the telephone waves shall be the same. Such a coil is theoretical, and cannot be obtained in practice. A loading coil is primarily one so designed as to provide a required amount of inductance, and must, of necessity, consist of several turns of wire. Moreover, to prevent attenuation, it is imperative that the resistance of the coil be kept as low as possible. To make the resistance of the coil low, the wire employed should be of copper of large size, and the number of turns of wire in the coil should be kept small. A reduction in the turns can, other things being equal, be most easily obtained by the use of iron for the core of the coil. If the coil is made entirely of copper, the effective resistance of the coil with the frequencies within the range of telephone periodicities will differ from the resistance by an amount corresponding to the losses due to eddy-currents in the copper. If iron forms a portion of the coil, there will be, in addition to the eddy-current losses in the copper, eddy-current losses in the core, as well as hysteresis losses in the iron, which will augment the difference between the resistance and the effective resistance. As it is impossible to eliminate the eddy-current and hysteresis losses entirely, the effective resistance of a loading coil will vary with

Digitized by Google

different periodicities, and thereby tend to produce distortional losses in the transmitted telephone waves. The difference between the resistance and the effective resistance, at telephonic periodicities, can be made much smaller in a coil composed entirely of copper than in one having an iron core.

Practical and commercial reasons demand an iron-cored load-

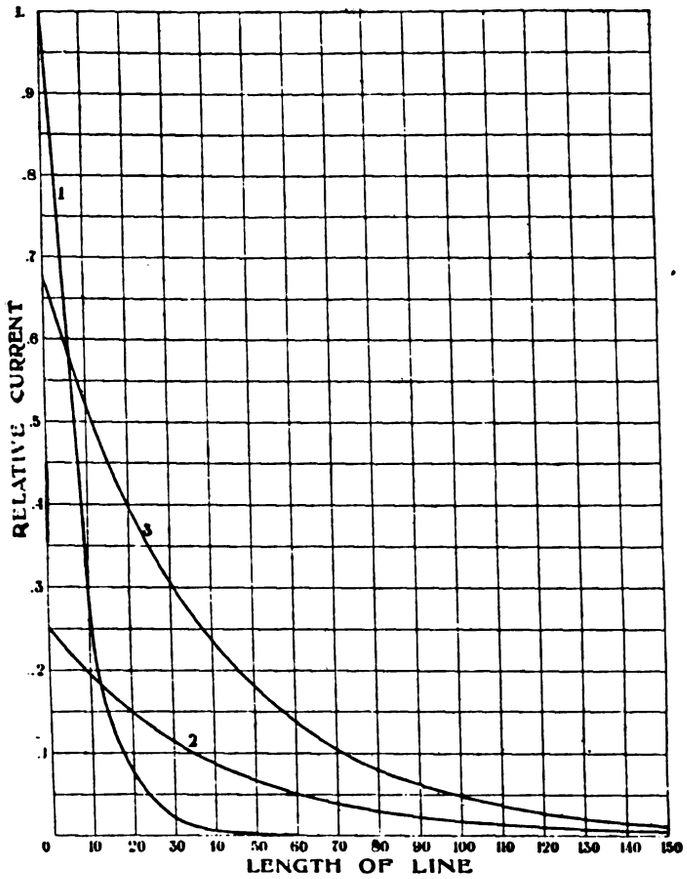

FIG. 1.

ing coil, provided that such a coil can be so designed that its use in a telephone circuit will not be productive of appreciable distortion. To determine whether, in practice, there was appreciably more distortion introduced by loading coils having iron cores, as compared with those made entirely of copper, the two circuits first loaded were equipped, one with iron-cored coils, and the other with copper inductance coils. The circuits were each about 1000 miles in length. The coils used on these two circuits were spaced alike, and had the same inductance and approximately the same resistance. The effective resistance of the coil having an iron core was about 15.5 ohms at a periodicity of 2000 per second and that of the copper coil 11.8 ohms at the same periodicity. These circuits thus loaded were compared with each other with the greatest care and no difference was apparent either in the character, or quality, of the telephone transmission. These tests are again confirmatory of the fact that the suppression or reduction of the waves of the highest periodicities of the voice waves does not appreciably affect the quality of intelligibility of transmitted speech. This experiment was considered as demonstrating conclusively the possibility of the commercial use of loading coils having cores of iron.

LOADING COIL.

A discussion of the theoretical dimensions of loading coils for different classes of circuits may be found in Dr. Campbell's paper, to which reference is above made. In practice the size and cost of the coil are factors requiring serious consideration. For aerial circuits, where the size of the line wire is large, and consequently the resistance of the circuit small, it is of the utmost importance that the effective time-constant, $\frac{L'}{R'}$ of the coil should be made as large as is consistent with reasonable cost. Except so far as the cost is affected, the size of the aerial loading coil is of no special moment, as the coils can be mounted singly upon the poles. The time-constant of a coil can be increased by enlarging its size, but such increase in size increases its cost. The best commercial loading coil is, therefore, the smallest coil that will give the required inductance and the largest effective time-constant.

Following the theoretical considerations as deduced by Dr. Campbell, the resistance of the coils which have been used on aerial circuits has been made 2.4 ohms. The design of the core, the permeability of the iron, the subdivision of the iron and the copper have been made such that a loading coil has been produced having an inductance of .25 of a henry, a time-constant of .048 second, at a periodicity of 1000 periods per second, and a bulk of approximately 314 cu. ins. This coil is toroidal in shape, 10 in. in diameter and 4 in. high. It has an effective resistance of 15.5 ohms at 2000 periods per second.

Coils designed to be used on cable circuits in which the size of wire employed is much smaller do not require to be made of as low resistance as the coil above described; consequently their size and time-constant may be made much smaller. Large numbers of cable loading coils have been placed in service, their design varying with the character of the circuit upon which they were used.

REFLECTION.

In the terminal apparatus at present used in telephony, or where there is a condition of non-uniformity in the character of the line, the telephone waves suffer a reflection, which, in many cases, is effective in materially increasing the attenuation. This

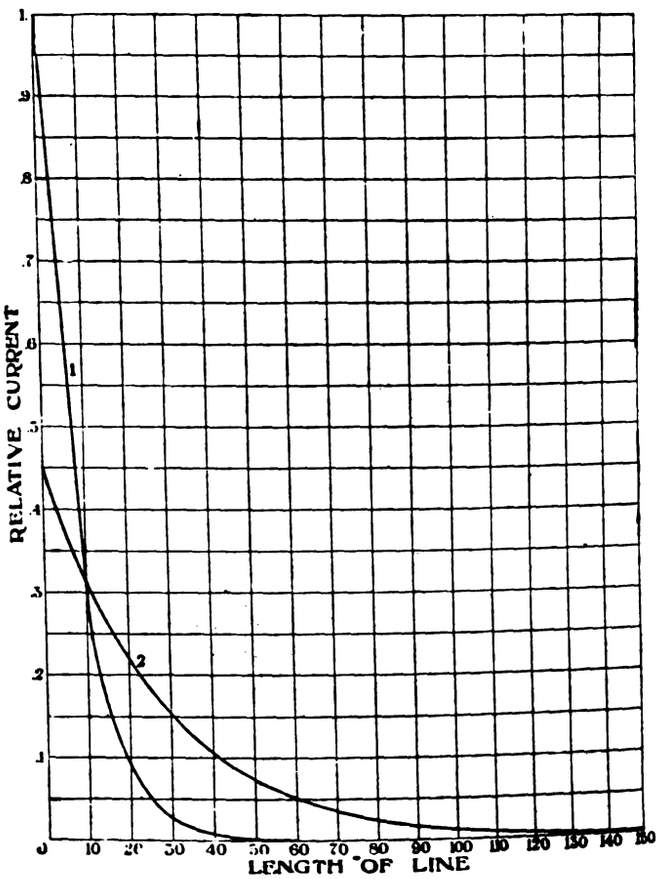

FIG. 2.

reflection is particularly pronounced at the point where an unloaded section of line is connected to a loaded section. The amount of reflection is greater the greater the divergence from homogeneity. Thus a section having large inductance per mile, when connected with a non-loaded section, exerts a larger reflective action than one having a small inductance per mile.

In practice, the effect of reflection is of very considerable im-

Digitized by Google

portance, particularly when the loaded section is not relatively long. Theoretically, these reflection losses may be eliminated by the use of a perfect transformer introduced at every point of non-uniformity in the line. Even could such a perfect transformer be made its introduction on commercial circuits is open to practical objections, and, as a substitute, its equivalent, in the shape of a series of coils of varying inductance, has been employed. This arrangement of coils of varied inductance is known as a "terminal taper." The arrangement of the several coils constituting the taper is such that a coil having an inductance somewhat less than that of the coils used on the loaded section is placed nearest the loaded line, a coil of inductance somewhat less than the first taper coil is placed next in order, and a coil of small inductance is placed nearest the non-loaded section, or the terminal apparatus. The spacing of the coils in the taper corresponds with that of the coils of the line of which it is to form the terminal.

RESULTS OBTAINED ON COMMERCIAL CIRCUITS.

The following figures illustrate the results which have been obtained on several typical commercial circuits. In what follows, all comparisons are made on the basis of relative attenuation between similar circuits loaded and unloaded, without reference in any way to distortion or quality of the transmitted speech. The curves shown in these figures are the results of actual tests, made on commercial loaded circuits, using standard terminal apparatus at the transmitting and receiving stations.

LOADED CABLE.

In Fig. 1 are shown the results obtained in tests of a heavily loaded standard telephone cable. In this cable the wires are .03589 of an inch in diameter, having a resistance of about 96 ohms per mile of circuit. The mutual capacity between the two wires of the circuit is .068 of a microfarad per mile. The inductance added to the circuit by the loading coils amounted to about .6 of a henry per mile. In this figure the abscissæ represent lengths of cable and the ordinates the relative strengths of current. Curve 1 is that representing the attenuation of current on an unloaded circuit as the length of cable is increased.

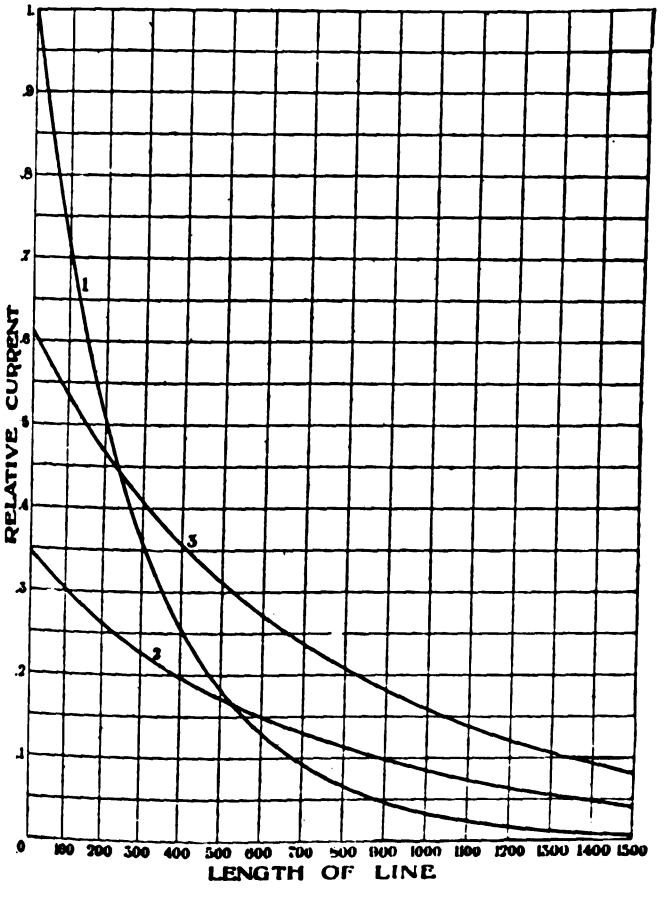

FIG. 3.

It will be seen that the attenuation increases very rapidly as the length of cable is increased. Curve 2 represents the attenuation on a similar circuit but loaded as above described, the terminal telephone apparatus being placed directly at the ends of the loaded cable, thereby obtaining the full effects of reflection. It will be noticed that the initial current on the loaded circuit is about one-quarter of what it is on the unloaded circuit. Moreover, the transmission on shorter lengths of the loaded circuit under these conditions is much poorer than the transmission over similar lengths of the same cable circuit unloaded. But the rate of attenuation per unit of distance is much less on the loaded than on the unloaded circuit; so that for the longer lengths of circuit the transmission is superior on the loaded circuit to that on the same lengths of unloaded circuit. Curve 2 shows the attenuation when no terminal tapers are employed and the reflection is a maximum. If terminal tapers are employed at the two ends of the loaded circuit and the telephone transmitting and receiving apparatus is connected directly to the tapers, the attenuation on the loaded circuit is represented by Curve 3. Here again it is seen that the initial current is considerably less than that on the unloaded circuit and that the transmission on short lengths of circuit is better on the unloaded than on the loaded conductors, but the introduction of the tapers on the loaded circuit has more than doubled the initial current and has shortened by about one-half the length of circuit which showed the unloaded circuit superior. A comparison of Curves 2 and 3 shows how great a factor the reflection losses are between the terminal apparatus and a loaded circuit and the importance of the taper in reducing these losses. In practice it has been found that reflection losses can be still further reduced and under special conditions almost, if not entirely, eliminated.

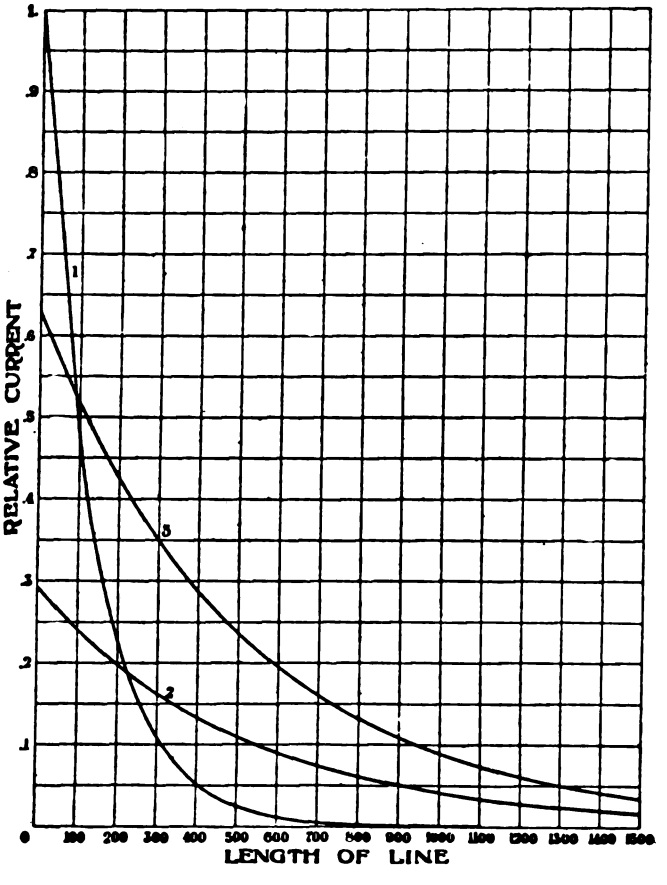

FIG. 4.

In the case above described a large amount of inductance has been added to the circuit. The results which have been obtained upon cables where less inductance has been added are shown in Fig. 2. In this case the cable is substantially similar to that

Digitized by Google

previously described. Upon it loading coils are placed so as to bring the inductance of the circuits up to approximately .17 of a henry per mile. In other words the inductance is less than one-third of that in the case just described.

In Fig. 2, Curve 1 is similar to that in Fig. 1 and represents the attenuation of the telephone current in an unloaded circuit in the cable. Curve 2 represents the attenuation in the lightly loaded circuit when no tapers are employed and the telephone transmitting and receiving apparatus are placed at the terminals of the loaded cable. It is to be noted that the reflection losses are much less in the case of the lightly loaded cable than is the case in that having the heavier loading. In fact for shorter lengths of cable the lighter loading is more effective in transmitting the telephone wave than the heavier. For longer lengths, however, the heavier loading gives better results. With proper apparatus at the terminals of the loaded cable to reduce reflection losses, much less attenuation would result than is indicated by Curve 2.

LOADED AERIAL CIRCUITS.

In Fig. 3 are shown the results which have been obtained on open-wire circuits composed of copper wire weighing 435 lbs. to the mile. On these circuits loading coils were so placed as to make an inductance of about one-tenth of a henry to the mile. Curve 1 shows the attenuation with various lengths of line upon a similar unloaded circuit, and Curve 2 shows the attenuation on the loaded circuit when the telephone transmitting and receiving apparatus are placed directly at the ends of the line without tapers. Curve 3 shows the attenuation under similar conditions when tapers are employed. The results resemble those obtained with loaded and unloaded cable. There is a large reflection loss which is considerably reduced when tapers are employed. Even with tapers the loaded line for shorter distances is inferior to the unloaded. The point particularly to be noticed is the relative slope of the curves in the two cases indicating that the benefits to be obtained from loading open-wire circuits are less than with cable circuits.

Fig. 4 illustrates the results which have been obtained from loading open-wire circuits using a conductor weighing 176 lbs. to the mile and having an added inductance equal to about .1 of a henry to the mile. As before, Curve 1 represents the attenuation on a similar unloaded circuit; Curve 2, the loaded circuit without tapers, and Curve 3, the loaded circuit with tapers.

GENERAL CONSIDERATIONS.

The above curves show the results which have been obtained by the use of coils of considerable inductance added to open-wire and cable telephone circuits and may be considered as typical of the results obtained on similar circuits of different capacity or composed of wire of different size. As before stated the curves illustrate simply the relative volumes of transmission under the various conditions described.

In the case of cables there is a distinct improvement in the quality of the transmission produced by the introduction of the loading coils, the voice of the speaker being received more distinctly. The high insulation which can be maintained at all times on cable circuits renders it possible to introduce loading coils upon the circuits without danger of materially augmenting leakage losses. The marked diminution in attenuation, the improvement in quality of transmission and the ease with which inductance coils can be placed on cable circuits without introducing other injurious factors, such as leakage or cross-talk with other circuits, renders the use of loaded cable circuits especially attractive.

The reduction of attenuation that can be obtained by the introduction of loading coils on air-line circuits, even under theoretically perfect conditions, is less than can be obtained on cable circuits. This difference in the effectiveness of loading between the two classes of circuits, as far as attenuation is concerned, can be explained by the fact that on a cable circuit the capacity is large and the inductance of the circuit itself is practically negligible, due to the proximity of the two wires of the pair. On aerial circuits, on the other hand, the distance between the outgoing and return wire is such as to make the capacity of the circuit much less, and its inductance much greater. This larger self-induction of the open-wire circuit operates to decrease the attenuation, and, as it were, to rob the loading coils of part of their usefulness. Again, the insulation of an aerial circuit cannot be maintained as high as that of a cable circuit, so that the added inductance due to the introduction of loading coils upon the line tends to increase the losses due to leakage.

Moreover, there is not the same improvement in the quality of transmission on a loaded aerial circuit as compared with a similar circuit unloaded, as is found between loaded and unloaded cables. Initially, open-wire circuits are practically free from distortion, whereas the distortion on cable circuits of long length is considerable. The addition, therefore, of loading coils to aerial circuits cannot be expected to effect any improvement in the quality of transmission, whereas in the case of cables the introduction of the additional inductance renders the circuits practically distortionless and effects a marked improvement in the clearness of the transmitted speech.

In presenting this brief summary of the operation of loaded telephone circuits, it is desired to make acknowledgement to Mr. H. S. Warren and Mr. E. H. Colpitts for the solution of the many problems involved in the design of suitable coils for use in carrying out this invention, and to Mr. W. L. Richards and Mr. A. N. Mansfield for the careful tests upon which the curves above shown are based.

THE TELEPHONE PROBLEM IN LARGE CITIES

Paper Presented at The International Electrical Congress at St. Louis

By F. J. Dommerque.

THE present hour confronts the telephone engineer with the problem to find adequate and economical ways and means to provide proper telephone service for many large cities, where the number of telephone users has increased enormously in late years, caused by a better appreciation of the usefulness and convenience of the telephone and the decreased cost of telephone service. In the last decade the population itself has shifted under the expansion of rapid transit; on the one hand the business men congregating in huge office buildings, on the other hand the residential districts radiating far out into the country. These altered conditions must be taken into consideration in the arrangement of new switching apparatus, which is to replace old equipment, now inadequate, obsolete and worn out.

When speaking of large cities, it would be drawing the limits too close to consider only New York and Chicago and the capitals of the old world; all cities with more than 100,000 inhabitants should be included and in fact all that will be said for cities of 100,000 pertains equally well to cities of smaller population, as long as they can be termed cities at all.

Telephone service must be reliable in all cases; it also must be quick and not involve any operation on the part of the subscriber. The cost of service must be reasonable; the business man can and will pay a greater amount for good service than the residence subscriber, but there should be no difficulty in arranging rates satisfactory to the latter by a judicious use of party lines and measured service.

It has been the general rule up to the present time to divide a large city into a number of districts; to locate a central office in each district and to connect these offices by trunk lines. When economy only is taken into consideration, this method of handling the telephone business is probably correct as in large cities the actual minimum of annual expenditure will be obtained with more than one office district, because the expense for the wire plant, which is the principal item of annual expense, decreases with increasing number of office districts, while the other items that contribute to the annual expense increase up to a certain point where the sum of all items gives a true minimum.

Paying, however, due respect to the quality of service, it is a plain fact that with the introduction of trunking the service must become less efficient, because, to begin with, it takes more time to put through a trunk call than a local call; as all trunk calls must be handled by at least two operators a greater liability to human errors is introduced; trunking also increases the apparatus and cable in the office, tending thereby to deteriorate the quality of transmission; and, finally, no matter how good the discipline of the operating room may be, it generally happens that in the busiest hours of the day when the service should be most rapid, all the trunk lines are in use and subscribers are forced to wait for connections. The trunking troubles are still more aggravated by the necessary evil of order wires. It is a wonder how in large cities where the percentage of trunking is very high, the operators are at all able in the busy hour to distinguish between orders. Anyone who ever listened in on an order wire circuit in a busy exchange will be convinced of the difficulties in that respect. If, therefore, money was no object, the ideal way of giving telephone service would be to bring all subscriber's lines into one switchboard. Looking at the problem from a physical standpoint, there is a limit to the size of the switchboard.

To begin with, it may be conceded that as a result of many years experience the multiple form of switchboard has shown itself as most adapted to satisfactory service. As a multiple board demands all subscribers to be in reach of every operator, it is absolutely necessary to decrease the size of the multiple jacks with increasing number of subscribers. The greatest number of lines that can be accommodated in a multiple section with the smallest jacks at present in commercial service (jacks with three-tenth inch centers) is 20,000 in an A section (a section upon which only local and outgoing trunk work is done), and 25,000 in a B section (a section used for incoming trunk work only). The capacity of a B section is greater on account of the gain in space by the absence of the answering jacks and signals and outgoing trunk jacks. However, 20,000 lines does not necessarily mean 20,000 subscribers; as by the aid of party lines and private branch exchanges the number of subscribers may be greatly increased.

Party lines being mostly used in residence districts, where the lines are of considerable length, effect a great saving in line expense and consequently permit of lower rates, which circumstance increases the number of residence subscribers; party line service naturally tends to increase the size of an office district.

Assuming that the use of telephones would become so general that one telephone would be required for every five people, and assuming furthermore that one-half of the telephone equipment would be used for a single line service, and the other half for party lines and private branch exchanges; and that the party line and private branch exchange subscribers would require only one-third as many lines as the other subscribers, in other words that three times as many party line and private branch exchange subscribers could be accommodated as there is line equipment in the switchboard, then with a board having a capacity of 20,000 multiple jacks, 10,000 single line subscribers and 30,000 party line and private branch exchange subscribers or a total of 40,000 subscribers could be given service without necessitating the use of more than one office. According to the above made assumption this would correspond to cities with not more than 200,000 inhabitants, or better expressed, all cities that will not increase to more than 200,000 inhabitants during the life of the switchboard.

There exists the possibility of extending the use of a single office to a larger city than 200,000 population by the aid of so-called "division systems," sometimes termed group-systems. Such systems subdivide a multiple board into two or more divisions so that only one-half or one-third or one-fourth the number of lines (according to the number of divisions) are multipled in each division, while *each* division contains answering jacks and signals for all the lines. A two-division board thus would contain 20,000 multiple jacks of the three-tenth inch type in each section of each division, giving a total of 40,000 lines. There would have to be a total of 80,000 answering jacks and signals, as each line would have to appear in *each* of the two divisions.

This doubling of answering jacks and signals, however, does not mean doubling of space, as in a two division system the answering jacks can be spaced close together (20 per strip), while in a straight multiple board they are spaced 10 per strip for good service; because in a two-division board are twice as many jacks for the same number of originating calls as in a straight multiple system. Seven years experience with division

Digitized by Google

boards has established the fact that more than two divisions will not give good and economical service; four divisions can give *good* service, but the service is not *economical* principally on account of the practical impossibility of using an intermediate distributing board, since the cross-connecting wires become unwieldy; hence, the possibility of distributing the load evenly over the operators or rather the possibility of loading each and every operator to the limit, is excluded. With two divisions the use of an intermediate distributing board is practical as not more than a three-pair cross-connecting wire is required.

Therefore, with a two-division system, 20,000 single line and 60,000 party line and private branch exchange subscribers can be accommodated on 40,000 lines in the switchboard, whence the use of a single exchange may be extended to cities with a population of 400,000.

Many telephone engineers are unfavorably disposed toward anything that involves labor on the part of the subscriber, and in a two-division system the subscriber would have to press one of two buttons upon his instrument according to the division upon which the desired subscriber is located; and this operation though involving only a minimum of attention on the part of the subscriber, is not quite as simple as just lifting the receiver off the hook to signal the operator. Where a two-division system should not find favor, the city must be divided into districts and trunk lines must be used. In such a case the number of districts should be kept small in order to keep the trunking in narow limits. In fact the trunking should be kept below 50 per cent., in other words, of all the originating calls not more than one-half should be trunked. This can best be accomplished by establishing one office with a 20,000 line board in the center of the densest telephone population, then select clusters of less dense telephone population and provide each of them with an office and trunk between them. In this arrangement all boards would be multiple boards as there would be sufficient local business to require a multiple on the A sections.

As soon as the district of *dense* telephone population becomes too great for one office, and, therefore, must be subdivided into more districts, the percentage of trunking will naturally rise; and from experience it is known that in New York and Chicago for instance the percentage of trunking exceeds 60 per cent. and has been considerably higher at the time when the offices or rather the switchboards were smaller. When the percentage of trunking is high the multiple in the A boards is not used much and it raises the question if it would not be better under the circumstances to trunk all the calls so that the A board would be a receiving board only, while the B board would contain a large multiple. Doing this, should offer an opportunity to simplify operation as the A operator's circuit could be made very simple. Also time should be saved in the average duration of a call on account of simpler and more uniform manipulations, in other words when all calls are trunked it should take less time to put up a connection on a trunk line than where only part of the calls are trunked.

From the aforesaid it follows that in an exchange without trunking the best service can be rendered and that the quality of service deteriorates with increasing percentage of trunking. It also is a fact that with large office districts the annual expense is greater than with small office districts. The question arises which of the two, better service with greater expense or inferior service with minimum of expense should be selected; or is there a compromise.

Where competition exists, as is now the case in all large cities of the United States with the exception of New York and very few others, that company which gives the best service is most liable to find the greatest favor with the public. Where the telephone service is in the hands of the government like in all principal European countries, the government certainly desires to give the best service if it only can raise the money. It seems, therefore, reasonable to say that the best service should be made the rule and that every effort should be made to render this best service with the least expenditure.

The principal item of expense entering into this problem is the line expense. Any reduction therein will be in favor of larger office districts, district being here relative, meaning a district containing a great number of subscribers and not necessarily covering a large area, though the larger the area the more marked the difference in expense will appear.

With large office districts more lines can be concentrated into heavy underground runs, which will reduce the relative cost of the conduit system. Larger cables can be used and larger cables are cheaper per conductor than small ones. The demand for larger cables has prompted the cable manufacturer to build cables with four hundred and more pairs. Of course the conductors in these cables had to be of a finer guage than had been the custom heretofore, but the development in transmitter design kept pace with the progress in cable manufacture so that these cables with fine guage wire do not deteriorate the transmission as long as the capacity is kept in reasonable limits. All these briefly mentioned items are in favor of large as against small office districts.

The introduction of party line service in the residence district has made the proposition of large offices still more favorable. With small office districts the management often was doubtful whether party lines would really be money savers, because the parties as a rule were located so far apart that the common line from the exchange to the point or points of connection with the party lines plus these party lines did not cost much more than individual lines direct from the exchange to each of the parties; the saving in the line expense in that case did not seem to be in accordance with the decreased revenue per party line. With large office districts the common line from the exchange to the connecting points is most likely long in comparison to the party lines and, therefore, a real saving results.

On the other hand improvements have been and are constantly made in the design of trunk circuits; the principal step in advance being the introduction of automatic features like automatic or machine ringing, which secure simpler operation and reduction of time, but involve complication in the apparatus.

In the now so largely exploited Strowger automatic telephone system trunking is carried on entirely automatically, the subscriber being made to perform what little is left of operating. This is a case of going to the other extreme where all calls as far as large exchanges are concerned involve trunking and where all the trunking is done automatically in the exchange with at present very complicated apparatus. It is not the purpose of this monograph to enter into a discussion of automatic versus manual exchanges; it may only be assumed that the automatic exchange can be made practical and it may further be expressed as a personal opinion that the vertical and rotating movement as applied in the Strowger switch is the keynote of automatic working.

With this in mind the exchange problem in large cities becomes entirely different. The trunking no more affects the service and, therefore, the choice between large and small offices or office districts resolves itself into a problem of economy pure and simple. In this case the engineer must find the true minimum of annual expense and be guided thereby in the selection of the number and location of the offices. The sum-total of automatic apparatus will be the same whether all concentrated in one building or scattered over many. The length of the trunk lines, however, varies, being shortest with all the switches in one building and increases with the increasing number of and distances between offices. The reverse is the case with the subscriber's lines, and there can be found a balance where, certeris paribus, the expenditure on trunk lines plus the expenditure on subscriber's lines gives a minimum.

So far the term "service" has been used to designate the more or less satisfactory arrangement and working of the apparatus either by operators or automatically; another phase of service is represented by the quality of the transmission of speech. Not much need be said in relation to this, as there are obtainable the most efficient transmitters and recievers, and it is only a matter of dollars and cents to obtain same; it is furthermore a question of finances to build the lines so that they will present sufficiently high insulation, low enough resistance and balanced induction and capacity.

Digitized by Google

Stress is here laid upon a good talking circuit for the reason that with the introduction of automatic exchanges this most essential requirement in any telephone enterprise has been sadly neglected. The advent of the Strowger Automatic exchange has also caused a return to the local battery at the subscriber's station for talking, which is contrary to the trend of the present moment toward centralization in all manually operated exchanges. Also the necessity of a ground connection at the subscriber's premises for signaling purposes is against modern practice.

After having disposed of the local exchange requirements for large cities, a few words may be added with regard to the toll and long-distance facilities that should be provided. Both the toll business and the long-distance business being of the same nature and closely allied, one switchboard seems to be preferable for both kinds of service. The switching apparatus for this purpose should be so located that either no cable at all or only a minimum amount would enter between the toll and long distance lines and the point where the same are switched to the local subscriber's lines.

As the toll and long distance lines are very costly they ought to be loaded to the fullest extent; to do this effectively the operator should be enabled to keep the lines busy all the time, therefore, only a few lines should be assigned to one operator (in Germany they assign only two lines to one operator) and provision should be made to make the connections with the utmost speed. For outgoing calls for such subscribers as frequently use the toll and long-distance lines provision can be made to call the toll board direct without going first through the local board, by providing a double signaling device; one being the regular signal upon the local board, operated by the subscriber taking the receiver off the hook, the other one being a second signal terminating in a distributing operator's section of the toll boards; this signal being arranged similar to the second signal in a two-division signaling system previously alluded to and being operated by the subscriber's pressing a button.

For incoming toll and long-distance work the same subscribers may have their lines multiplied through the toll board so that every operator can connect to them direct.

All toll boards in large cities should be provided with ticket carriers, something along the line of the cash system in large department stores which are operated by compressed air or belts.

By the use of composite circuits much time can be saved, as the calls may be ordered up by telegraph, leaving the lines ready for actual conversations.

A PECULIAR CASE OF INDUCTION

By Arthur Rich.

OWING to the fact that a large number of the small exchanges that are in existence at present, and a large number that will be built in the future, are operated under the "McClure" principle of common return; and the electric light and power systems in small towns are using alternating current of from 1,000 to 2,000 volts potential, the trouble-man in a small exchange often confronts difficult problems in the line of peculiar cases of induction. Such a case recently came under my observation, and owing to its peculiar phenomena it may be of interest to some of my fellow "trouble shooters."

The difficulty was a peculiar hum in the operator's head receiver when no lines were connected and no cams were open. The system is a well-constructed "copper return," with poles in the alleys. The electric light system is of the alternating type, using a current of 2,000 volts potential, with poles in the streets. The current for the entire business district is transformed down to 100 volts by two dry-cored transformers, placed on poles in the street. The wiring for the exchange comes in on the ceiling near the switchboard, and there is a droplight directly back of the switchboard.

A few instances of the interesting phenomena were, that when the operator stood directly under the light conversation would be impossible on account of the roar, while fifteen feet away toward the distributing frame it was perfectly silent. Going in the opposite direction the hum decreased slightly. The hum might at any time be entirely stopped by the operators touching the transmitter with the hand. Withdrawing the receiver plug from the jack stopped the hum, but on bringing the plug within three inches of the transmitter it was as loud as when plug was in position. A telephone placed anywhere in the room, away from the distributing frame, entirely disconnected from anything, displayed the same phenomena as the switchboard, only in a less marked degree.

Technical journals were consulted to no avail, but I finally happened to notice a peculiar wiring of the transformer, and on investigation found that it was so wired as to bond one side of the primary and secondary, while the other side of the primary was grounded. This, of course, threw the normal 100 volts between the two sides of the line, but left a pressure of 2,000 volts between one side and the ground. This cleared, our trouble was over.

Our theory is that the 2,000 volts pressure flowed electrostatically to the nearest ground conductor, which was the distributing frame, and taking the path of least resistance flowed through the receiver.

The operator standing directly under the light was at the point of highest potential, consequently the loud hum on going toward the distributing frame; the potential rapidly decreased until it became zero at the ground conductor. The switchboard is so wired that the frame of the transmitter is grounded, so when the operator touched it he became the point of zero, thus stopping the flow through the receiver.

I am informed by electric-light men that 2,000-volt transformers often become punctured, bonding the primary and secondary. They also state that it is their custom to "Let 'em go so long as they don't waste too much current."

Telephone men would do well to see that such things are not let go, as it is dangerous, not only to their apparatus, but also to the life and limb of their workmen and operators.

FEATURES OF THE DUNBAR TWO-STRAND COMMON-BATTERY SYSTEMS

Paper Presented at the International Electrical Congress at St. Louis.

By Prof. J. C. Kelsey, *Purdue University.*

WHEN a company or engineer, or group of engineers, enter upon the development of a certain line of business, based on an original idea, their succeeding efforts seem to follow along a well defined and slowly widening path. Nothing revolutionary appears on the surface, and the improvements revealed to the customers are simply increments to the original idea. This is particularly true as concerns the telephone industry. During the period of Patent-Office protection, the various developments brought out by the engineers connected with the telephone interests followed each other in a quiet and logical manner,

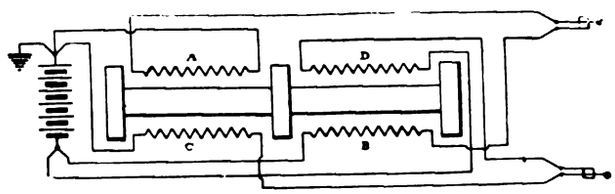

Fig. 1.

and at no time did they depart far from a beaten path. And when the Independent interests were given freedom of thought and action, their efforts followed along this same beaten path. Only for a short time, however, for their work took on the marks of originality, and departed entirely from past traditions. In pointing out the instance where this was accomplished, the features of various succeeding commercial systems will be briefly considered.

One of the first efficient landmarks in the switchboard science is the series grounded system. The earth served as a return, and the low resistance line drop was necessarily dissociated from the line during connection. This was accomplished by a two-strand cut-off jack, having one spring for the talking contact, and a sleeve or thimble to guide the plug, and to hold it properly. The entrance of the plug raised the spring from a rest contact, which was connected to the drop. As the board grew in size, a busy test for the multiple of jacks became necessary, hence the use of sleeve as a test terminal. Having no operative function, otherwise the multiple of sleeves was normally insulated from everything. When the plug was inserted, being of solid metal, it brought the sleeves into contact with the talking circuit, which put them at the potential of the subscriber's earth. To utilize this changed condition of sleeves during usage, a battery was placed in the operator's talking set in such a manner that when the listening key was closed, the tip of the plug assumed the potential of the battery, which, upon coming into contact with a grounded sleeve, caused a flow of current in the operator's receiver, and the subscriber's receiver as well.

The advent of the trolley system changed the telephone map, so to speak. To avoid the disturbances, a metallic circuit became necessary for most of the lines, and its connection with a grounded board was nicely accomplished by placing a repeating coil directly in the metallic line. In many places, the number of metallic lines grew to exceed the number of grounded lines, which led to the demand for a board giving preference to metallic lines, as two repeating coils between two metallic subscribers was far from desirable. This resulted in a somewhat revolutionary step—the bridging, self-restoring drop system.

This system began the era of local electrical actions in conjunction with the talking circuit. The sleeve was still the test terminal, and had the added function of conducting the current through the restoring winding of the drop. The test terminal was normally at earth potential, through the restoring winding, and was raised by the entrance of the plug. To detect this changed condition of the sleeve, the induction coil secondary and the receiver windings were halved, and a ground placed at their center, so that the closing of the listening key would give the test, and the circuit not be unbalanced during ordinary operating. At this stage, the two-strand system stood a chance of usage, but for some reason the designers did not care to use the sleeve as a combination talking and testing terminal. So they added a third contact, or a second talking spring, to the jack, and passed from one-strand into three-strand practice. The repeating coil was still evident, to connect dissimilar lines. But the main, or revolutionary, feature was the departure from the cut-off principle, by the use of a permanently bridged line drop, which was made possible in a multiple system by the simple effacement of the signal proper during a cord connection.

The use of a permanently bridged line signalling apparatus, and its effacement by auxiliary contact means, had its influence upon the next, or common-battery era. In this system, the battery and line relay is permanently bridged across the line circuit, and the line signal proper, or lamp, is effaced, or partially extinguished, by means of devices working in conjunction with the sleeves. For some reason this system has not been given general adoption.

The next system, the present licensee common-battery system,

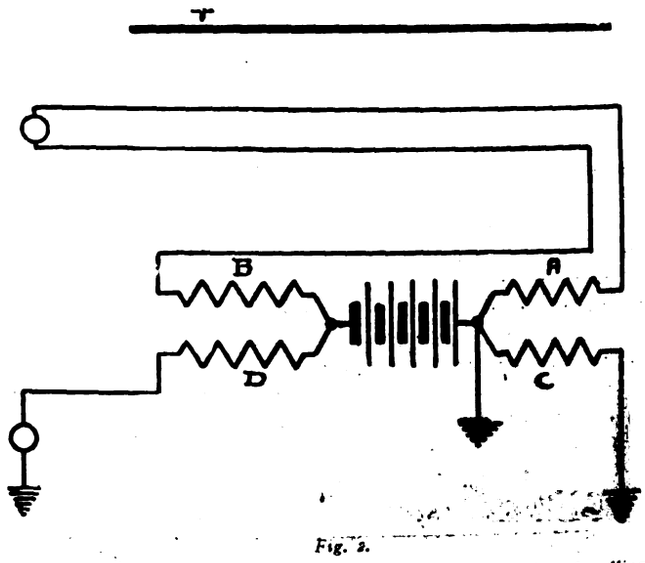

Fig. 2.

shows a return to first principles, inasmuch as the line-signalling apparatus is entirely dissociated from the line when on connection, and the subscribers talk through the clearing-out signal, now known as the disconnection signalling apparatus. The use of three strands came naturally into use, as the restoring winding had the same relation to the sleeve, or test terminal, as the cut-off relay winding of the present system has. In fact, there is not any evidence that the two-strand system was considered.

As the repeating coil is used in the first two-strand common-

Digitized by Google

battery system, brought out by the Independent interests, having double disconnect or supervisory signals, it must be shown that while they perform many of the same functions, in both licensee and Dunbar systems, there is a radical and necessary difference. The repeating coil that will operate successfully with the Dunbar circuit will not operate successfully with the licensee circuit. There is a reason, and that is, the Dunbar circuit is confined to metallic lines, while the licensee circuit embraces three conditions of service—metallic and metallic, metallic and grounded, and grounded with grounded.

When the common-battery systems were placed in operation, the cord circuits were equipped with a repeating coil, having four windings, arranged on a core, as shown in Fig. 1. The quarters of the coil belonging to the tips of the plugs, *A* and *C*,

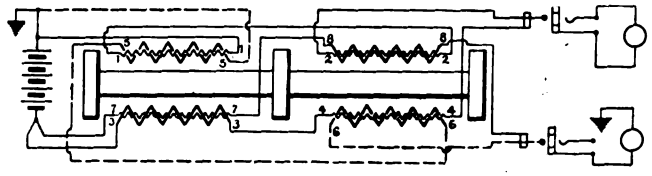

Fig. 3.

are wound on what we may call the left end of the core, while the quarters belonging to the rings, or other talking strands, *D* and *B*, are wound on the right, making two possible separate magnetic circuits, acting in the same direction. In Fig. 2, the use of the coil in circuit is illustrated, in which *A* and *B* are the quarters furnishing current to the metallic line, and *C* and *D* the quarters connecting the grounded party. According to practice, there are three grounds when a grounded line is concerned. One at the subscriber's station, one at the arrester frame, and one at the battery. This means that when a cord circuit is placed in connection with a grounded line, the tip quarter of the coil, *C*, is short-circuited.

If, according to Fig. 2, the metallic line parallels the trolley for considerable distance, both its wires are subjected to an electrostatic potential equivalent to the electromagnetic potential of the trolley wire. These electrostatic charges, alternating in character, are seeking the earth, and pass through windings *A* and *B* on their way. If *A* and *B* presented equal retarding effects to these alternating changes, then balance would result, and a quiet connection given. Unfortunately, the windings *A* and *B* do not present equal effects toward these charges, and great noise results upon a grounded connection. The effects are unequal in *A* and *B*, because the windings *C* and *D* are unequally loaded. *C* is virtually short-circuited, and has the greatest possible weakening effect on the inductive properties of winding *A*. Winding *D* having a line, instrument and common return in circuit does not have as great a weakening effect on *B*, as *C* has on *A*, hence the unbalance, and the consequent noise.

As the licensee companies had an object in maintaining grounded service, a coil had to be devised which would preserve the static balance under all conditions of service. The condition in question is the metallic and grounded connection, which means that the tip quarter of the coil on the grounded side is idle. In Fig. 3, the idle quarter has been represented by dotted lines, as section *5* and *6*. Tip eighth, winding *1* of the metallic side, and the dotted tip eighth winding *5* of the grounded side, start out in pairs at the same end of the core. Likewise, the metallic ring eighth, *3*, starts out in pairs with grounded ring eighth, *7*. On the other side of the core, or end, a double transposition takes place, as *8*, the grounded ring eighth, pairs with *2*, the metallic tip eighth, while *4*, the metallic ring eighth, pairs with the dotted grounded tip eighth, *6*.

The balancing effect may be better shown by Fig. 4, in which the various sections are connected in circuit. As connection with a grounded line renders the grounded tip quarter useless, it will not be shown. An inspection shows that grounded rings *7* and *8* have equal loading effects on each end of the core. By transposition, winding *7* affects the ring side of the circuit at *3*, exactly as *8* affects the tip side at *2*. Therefore, each quarter of the coil on the metallic side presents equal inductive resistance to the alternating static charges.

There has been considerable conjecture among licensee employees as to the reason that the improved eight-section coil will not permit of a ground at the arrester frame, or short-curcuiting of the grounded tip quarter, as did the older four-section type. When a coil gets down on a metallic circuit, the transmission is muffled to a serious degree, when the eight-section coil is used. The reason would be that the old coil had two separate magnetic fields, one of which could be short-circuited or idle without affecting the other. In the newer coil, a short-circuited quarter would affect the entire core, and render it non-inductive, and not efficient as a repeater.

As a non-inductive relay appeared in the Dunbar circuit, nothing yet appears of a revolutionary nature. The series grounded local battery system had a winding in the circuit as a clearing-out signal, through which the voice currents passed. The licensee system has a clearing-out signal through which the voice currents pass. So has the Dunbar original system. What is the difference? The licensee non-inductive supervisory relay has two windings, eleven ohms of copper, and 100 ohms of German silver wire, wound on the exterior of the copper winding, of few turns, and having no inductive value. The 100-ohm shunt did not materially weaken the power of the ten-ohm copper winding in connection with its direct-current functions, but when in the path of voice currents, acts as a direct circuit without any magnetic energy being set up, and consequently does not affect the rapidly changing frequencies to their disadvantage. The non-inductive relay of the Dunbar system is a differential relay, having two windings of equal and opposite value, and having the same relation of the core. If the coils were wound on the respective ends of the core, lines of force would be set up in the respective

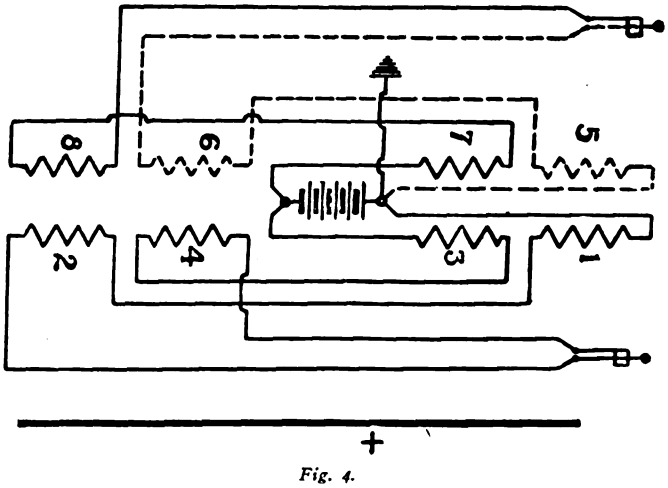

Fig. 4.

ends of the core of opposite value, and neutralization would take place. But when alternating currents of extremely high frequency pass through these windings, a neutralization would tend to take place, but does not, because the lines of force do not have time to thread through the neighboring coil; hence energy is restored to the circuit, which makes the end-on relay inductive to a certain extent. To cause complete neutralization, it must be done electrically, and not through magnetic means. If the coils are superimposed upon each other, then a neutralization takes place between the forces tending to produce magnetic energy, thus killing the evil at its inception.

What is the difference, then, between the Dunbar and the licensee systems, if each makes use of a cut-off relay, a repeating coil and a non-inductive cord relay? There is a great difference in the electrical actions involved, necessitated by the use of a talking strand as the means of operating the cut-off relay, and acting as a test terminal, in addition to its natural function. And, in the absence of the third strand, the act of testing a busy line has to be particularly safeguarded, in order to prevent the subscriber from being seriously annoyed while talking to another party.

Digitized by Google

Fig. 5 shows the original Dunbar two-strand system. The subscriber called central by removal of receiver, which allowed battery to flow through line relay, *LR*, out on the line through contact at *a*, thence back to the ground at *b*. The entrance of the plug causes battery to flow through winding *B*, relay *C O R*, thence back to the ground through winding *A*. The current being equal in *A* and *B*, the relay has no magnetic strength, and the lamp circuit of *A L* remains open. Right here is the remarkable feature of the system, that the cut-off relay is energized by current flowing through the talking circuit, without impairing the talking qualities in the least. The energization of relay *C O R* brings out another original feature, the simultaneous disconnection of the line signalling apparatus, and the connection of a normally disconnected multiple jack. This normal disconnection of the multiple jack from the line gives the advantage of a reliable busy test.

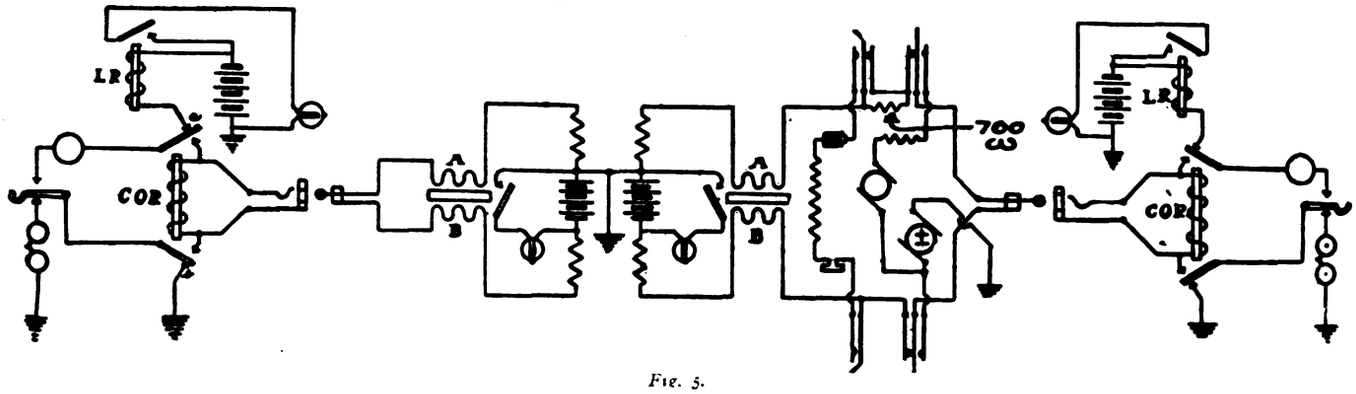

Fig. 5.

Another remarkable feature is shown in the busy test method. The test is a natural one, and the touching of the calling cord tip to the sleeve of a busy line jack, and is similar to that of the licensee systems, inasmuch as the touching of the tip to the busy sleeve stores up energy in the tip quarter of the repeating coil. The withdrawal of the plug tip causes a discharge of this stored energy into the operator's bridged receiver, and into the circuit of the calling party. But the Dunbar subscriber would be painfully aware of the test being made, while the three-strand licensee subscriber would not. The touching of the grounded tip to the sleeve talking terminal would materially lower the potential of the terminal, and cause a vicious receiver click in both talking lines. To prevent this, the listening key is arranged so that its use will remove a short-circuit from about the 700-ohm resistance placed directly in the testing circuit. This modifies the testing click in the subscribers' receivers considerably. There might be an objection to this method, as it introduces a 700-ohm resistance in the talking circuit of two connected parties, should the operator listen in. As she has double supervision, there is no reason why she should do so.

Inserting the calling plug lights the supervisory lamp, because the low resistance ground on the sleeve line side unbalances the differential windings and causes magnetic energy to be operative on the relay armature. More current will flow through *B'* than through *A'*, until the ground is removed by the subscriber removing the receiver. Then the windings neutralize, and the lamp is extinguished.

Another marked feature is the necessity of a temporary source of energy to hold the cut-off relay during the act of ringing. As the multiple is normally disconnected from the line, and its connection with the line depends upon the energization of the cut-off relay, and the energization of the cut-off relay depends upon the current flowing over the cord circuit, it follows that the necessary opening of the cord circuit in the act of ringing shall not deprive the cut-off relay of energy. This was accomplished by means of an alternating-current generator, which was connected to the sleeve side only. A direct-current generator was bridged across the circuit, and supplied the cut-off relay with direct current. Later, it was found that the ordinary exchange battery connected to the tip side through a suitable impedance would accomplish the same purpose as the direct-current generator. The idea is shown in Fig. 6, a later circuit, which supplied generator current out on the tip side, while the main exchange battery supplied energy to the cut-off relay.

At this stage the Independent designers made a revolutionary move. They departed from the repeating coil, they departed from the non-inductive relay, the only semblance being in the cut-off relay principle, though utterly unlike in operation. The era of double disconnect retardation system began. What were the technical reasons why the differential system, with its repeating coil, its non-inductive relay, and ground at the subscriber's station should be relegated, and the retardation system made standard? Both are designed for metallic service exclusively. The principal weakness was in the ground at the subscriber's station, which is objectionable for many reasons. The difficulty of a fair ground for selective ringing is known, while this system had to have a good ground, a real ground, of lowest possible resistance, in order that the differential relay could be

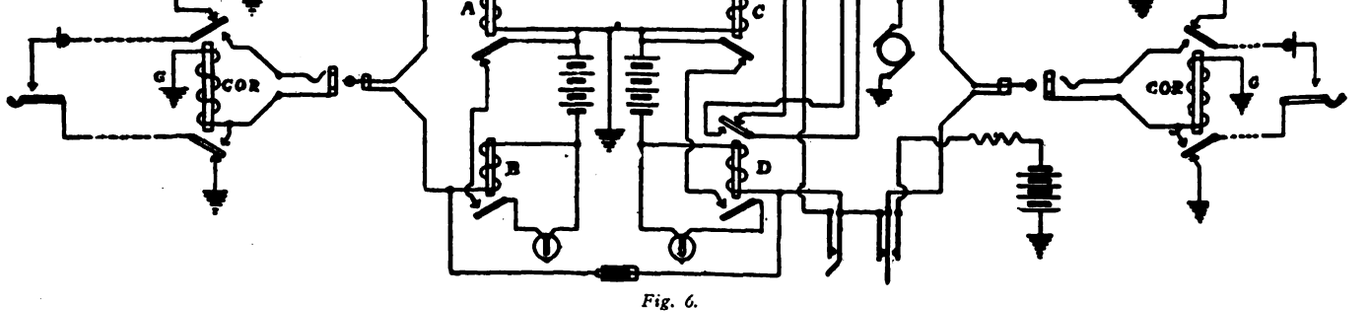

Fig. 6.

Digitized by Google

reliably operated. Supposing the grounds to be perfect, another difficulty presents itself—that unrelenting enemy of grounded telephone practice—earth currents due to the street railway companies. Potentials of different values exist on every line, making the operation of the differential relay a great uncertainty. And its peculiar dependence upon its external connections as a switchboard makes it unique, though not a weakness.

When the ground at the subscriber's station was changed to the ground as one terminal of the cut-off relay, *G*, in Fig. 6, the differential relay had to be abandoned, because there is no possible way that a neutralization could take place between windings *A* and *B*, when the subscriber removed the receiver. The 500-ohm cut-off relay would short-circuit winding *A* to a certain extent. So windings *A* and *B* were placed on separate cores, as it were, *B* being the winding of a back contact relay, while *A* is the winding of make contact relay. When a party calls in the usual manner, the operator would insert the plug, which would put relay *A* in series with cut-off relay *C O R*. Both would be energized, *C O R* cutting off line signalling apparatus, and connecting the multiple to the line, while relay *A* closed the circuit of the supervisory lamp. As the receiver is supposed to be off the hook, *B* is energized, and the lamp circuit broken.

The test feature is a distinctive one, consisting of a 5,000-ohm relay, which armature contacts, when closed, put a ground on the primary circuit in such a manner as to cause a battery flow through the primary winding, and induce a current in the secondary. Being of a great number of turns, and highly inductive, it does not cause an appreciable reduction of the terminal potential, and only an experienced telephone user can detect the test made on his line. The testing relay serves the entire operator's position, and is necessarily disassociated from each talking connection. Relay *D*, acting in series with the cut-off relay, *C' O' R'*, serves this purpose, and also closes the talking circuit, and the supervisory lamp circuit also. When the subscriber answers, relay *C*, has a function likened to relay *B*, simply opening the supervisory lamp circuit.

Condensers connect the answering and calling circuits instead of repeating coils, and serve to repeat the fluctuating voice currents. The circuits are individualized by the relays, which also control the direct-current supply as well. The circuits in Figs. 5 and 6 bear a very close resemblance to each other, having the same features practically; first, the temporary energization of the cut-off relay during the act of ringing; second, the current of cut-off relay energization being supplied over the strands of the talking circuit; and, third, the combined use of the sleeve as a testing and talking terminal.

Both systems have a normally disconnected multiple jack, a normally connected line-signalling apparatus; are designed for metallic service only, and it may be said that the four years' effort of the brainiest, cleverest and most experienced telephone engineers ever assembled together in the employment of one company simply resulted in the removal of the ground from the subscriber's station to that of the ground at the exchange cut-off relay terminal, which fact strongly proves the genius of the inventor of the first double supervisory two-strand telephone system.

When one remembers the herculean difficulties confronting this and other groups of Independent telephone engineers, the limited experience of the past, working in an entirely new field of action, one cannot help but realize that this apparently simple transfer of grounds represents many mile-posts in the advance of telephone development.

QUERIES

Questions on any subject relating to telephony will be answered on this page.

EXTENSION INSTRUMENT TROUBLE.—(427.)

We have a main and extension instrument connected as shown in the diagram, so that when the main instrument is in use the line to the extension is opened at the hook switch. Why is it that portions of the conversation can be overheard at the extension when the main instrument is in use?

A. D.

With the arrangement shown the line to the extension is

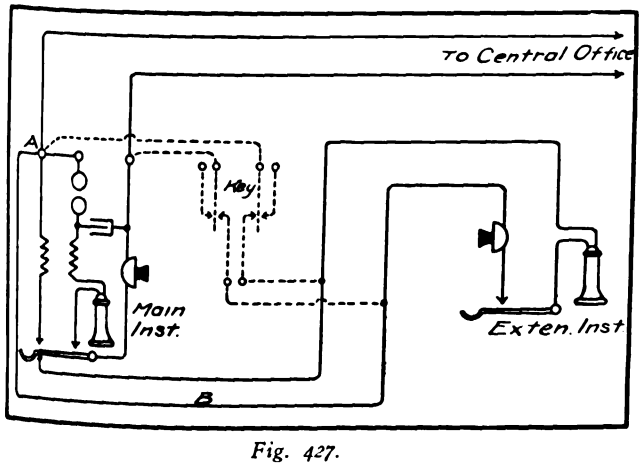

Fig. 427.

opened on one side only when the main instrument is in use, and the effect at the extension is due to the variations in the electrostatic charge on the side of the line which is not opened. If a source of electromotive force is connected to a wire which is open a current will flow from the source into the wire and charge it, the amount of charge depending upon the potential of the source. In the case in question the variation in the resistance of the transmitter at the main instrument causes changes in the value of the current flowing in the line, and consequent changes in the line potential at all points throughout its length, these changes being due to the varying *C R* loss. Thus the potential at the point *A* is constantly varying, and the static charge on the wire leading to the extension varies directly as the potential at *A*, and for this reason there is a continual flow of current in the wire *B*, and the receiver of the extension instrument is effected and the conversation at the main instrument repeated.

This condition can be avoided by connecting the extension through a switching key so that both sides of the line are opened when the key is operated. This arrangement is shown by the dotted lines in the diagram.

TRANSMITTERS.—(428.)

Will you kindly describe to me the difference between a transmitter used in connection with the local battery system and one used on the common battery system? Can a local battery transmitter be used by a common battery line?

B. J.

With reference to transmission the point of distinction between a local and common battery telephone lies in the fact that in the case of the latter, the transmitter being in series with the line, the resistance of the transmitter circuit is higher than that of the local battery telephone, so that in order to make the variation as great as possible, the resistance of the transmitter must be made high. The average resistance of a local battery transmitter is about 10 ohms, while that of the common battery transmitter is about 50 ohms. A local battery transmitter cannot be used on a common battery line, because its low resistance would allow an abnormal flow of current, which would result in "frying" the carbon. A common battery transmitter can, however, be used with a fair degree of success on a local battery telephone.

Digitized by Google

THE WEEK'S MESSAGES

FINANCIAL.

MONROEVILLE, IND.—The Monroeville Home Telephone Company has increased its capital stock from $25,000 to $75,000. S. E. Mentzer is the president of the company.

JACKSON, MISS.—The West Point Telephone and Telegraph Company's annual report gives its gross receipts at $4,174.59, while its expenses are given as $2,878.92.

WAVERLY, MO.—The Waverly Telephone Company has increased its capital stock from $35,000 to $50,000.

OCEAN PARK, CAL.—The Home Telephone Company has asked for a franchise in this city.

POMONA, CAL.—ThePomona Valley Telephone and Telegraph Company has paid its first semi-annual dividend on an eight per cent. basis. The company is composed of 150 stockholders and has at present 750 telephones in use.

FRANCHISES.

SAN BERNARDINO, CAL.—The San Bernardino County Supervisors have accepted the bid of Frank B. Daley, representing Nathan W. Tarr, for a telephone franchise along the county highways running into San Bernardino.

ALTON, ILL.—The city council has granted a franchise to the Fosterburg Telephone Company.

TURNER, KAN.—The Independent Telephone Company of this city, which is under the management of W. A. Strickland, will ask the city of Argentine for a franchise.

OLD TOWN, ME.—The city clerk reports that the Bangor Automatic Telephone Company has accepted the terms of the franchise for operating in this town.

FREMONT, NEB.—The Fremont Telephone Company has been granted a franchise to do business in this city.

VENTNOR, N. J.—The Atlantic Coast Telephone Company will ask the city council for a franchise to lay an underground telephone line in this city. The company proposes to lay all of its wires in conduits.

ONEIDA, N. Y.—The Rome Telephone Company has been granted a franchise in this town.

CINCINNATI, OHIO.—The Queen City Telephone Company has asked for a franchise at Locland.

COLUMBUS, OHIO.—At a meeting of the directors of the Columbus Citizens' Telephone Company it was decided to issue $300,000 worth of six per cent. preferred stock, the proceeds to be used in making the needed improvements.

LEXINGTON, VA.—The Lexington Town Council has granted a franchise to the Lexington Telephone Company for a period of thirty years for a consideration of $75. The company will at once enlarge the plant at a cost of about $5,000.

GREEN BAY, WIS.—A committee on ordinance will favorably report to the common council the application of the Valley Telephone and Telegraph Company for a franchise in this city.

COMBINATIONS.

AUGUSTSA, ARK.—The M. H. Patterson Telephone Company, of Augusta, has purchased the plant of the Clarendon Telephone Company, of Clarendon.

JACKSONVILLE, GA.—All of the property of the Jacksonville Telephone Company has been bought by G. K. Gerow for the sum of $5,000.

NASHVILLE, ILL.—The Southern Union Telephone Company of this city has disposed of all its lines in Coulterville to the Coulterville Telephone Company. The new company has organized, with the following officers: J. I. Higgs, president; C. N. Laubenheim, secretary; R. M. Burns, treasurer. The line will be extended to Marissa.

BALDWINSVILLE, N. Y.—A mortgage by the Baldwinsville Telephone Company to the Empire Trust Company of New York City has been given for $30,000. William H. Tappan is president of the company and James K. Whittaker treasurer and secretary.

COMANCHE, TEX.—J. P. Wilkinson has purchased the entire business of the Comanche Telephone Company.

NEW COMPANY NOTES.

TALUCAH, ALA.—The Intercounty Telephone Company, of Talucah, has been incorporated with a capital stock of $2,000. The incorporators are: C. L. Hogeboon, C. B. Hogeboon, Gus May, A. M. Llewellen, H. C. SiSmpson, J. B. Crowder, E. K. Cerrie, William Stringer, Cal Johnson, R. D. Cherrie, E. T. Giers and G. D. Campbell.

CORDELE, GA.—The Farmers' and Business Men's Telephone Company has been organized, and has been granted a franchise to do business in the city of Cordele. J. C. Ledbetter is president.

YORKTOWN, ILL.—The Yorktown Telephone Company has been organized with the following directors: George Matthis, M. R. Thackeberry, George Burden, P. S. Johnson and R. B. Senseny. The company will be incorporated with a capital stock of $5,000, and is a consolidation of the Yorktown-Hoopole and the Dingley-Thomas-New Bedford lines.

SCOTTSVILLE, KY.—The Scottsville & Barren River Telephone Company has been incorporated with a capital stock of $125, by W. B. Ray, R. F. Hood and J. T. Hunt, of Scottsville.

OAKLAND, MD.—The farmers in the southern section of this county and the adjoining territory of West Virginia have organized a mutual telephone company to be known as the Red House Telephone Company of Garrett County. Its lines will extend to the line of the West Virginia Central Railroad, and cover the southern section of this county. Henry Sisler is president, Mr. Arnold, vice-president, and P. F. Snyder, secretary. The company already has some lines in operation and will add more as they are needed.

GRAND LEDGE, MICH.—The Grand Ledge Telephone Company has been incorporated with a capital stock of $10,000. The officers are: Clark Smith, president; W. H. Sutherland, secretary, and Daniel Shadduck, treasurer. Austin Shipman and D. G. Kennedy, together with the president and secretary, constitute the board of directors.

HANOVER CENTER, N. H.—The Hanover Center Telephone Company has been incorporated with a capital stock of $1,000.

ALMA, N. Y.—The Alma Telephone Company has been organized with the following officers: E. J. Richardson, president; N. I. Strait, secretary and treasurer; W. H. Dunn, W. O. Watson, R. R. Gowdy, S. R. Branes and Lewis Perry, directors.

CANASTOTA, N. Y.—The Canastota Telephone Company has been incorporated with a capital stock of $25,000. The directors are C. J. Wood and T. H. Ferris, of Utica, and J. W. Souter, of Canastota.

KITCHAWAN, N. Y.—The Kitchawan Telephone Company has been incorporated with a capital stock of $1,000. The directors are: B. L. Chadeayne, E. G. Von Pim and H. B. Forman.

BOLIVAR, OHIO.—The Tuscarawas Valley Telephone Company, of Bolivar, has been incoroporated with a capital stock of $2,000, by Earl D. Fisher, John W. Keel, C. J. Pfau, S. B. Hennis and H. L. Fisher.

JUNCTION CITY, OHIO.—The Rush Creek Telephone Company, of Junction City, has been incorporated with a capital stock of $5,000, by W. G. Tuttle, W. M. Klinget, J. M. Elder, Joseph M. Folk and B. C. Elder.

NEWCASTLE, OHIO.—The Newcastle Telephone Company has been incorporated with a capital stock of $3,000, by J. W. Dillon, Abe Horn, W. L. Berry, W. C. Wilson and W. S. Crater.

NORMAN, OKLA.—The Farmers' Central Telephone Company, of Norman, has been incorporated with a capital stock of $5,000, by G. E. Fuller and J. W. Abshier, of Franklin, and J. P. M. Haun, of Norman.

BEND, ORE.—The Deschutes Telephone Company has been incorporated with a capital stock of $3,000 and bonds $3,000, to operate telephone systems in the towns of Bend and Prenville. The officers are: W. E. Guerin, Jr., president and manager; A. L. Goodwillie, vice-president and treasurer; V. J. O'Connor, secretary.

BUTLER, PA.—The Pittsburgh-Butler Telephone Company has been incorporated with a capital stock of $25,000. Treasurer, T. J. Shufflin, Butler. Directors: J. G. Splane, J. S. Weller, Pittsburgh; T. J. Shufflin, Butler.

COUDERSPORT, PA.—The Allegheny Valley Telephone Company, of Coudersport, has been incorporated with a capital stock of $5,000.

EDINBORO, PA.—The Edinboro Telephone Company has been incorporated with a capital stock of $6,000. Treasurer, G. W. Minium, Edinboro. Directors: J. F. Bigler, C. L. Darrow, Fred Le Seur, E. P. Perry, I. R. Reeder, W. A. Proud, G. W. Minium, Edinboro.

ERIE, PA.—The Union Telephone Company, of Erie, has been incorporated with a capital stock of $10,000. Treasurer, W. B. Barnard, Philadelphia. Directors: Wm. B. Trask, W. H. Wilson, James Russell, Erie; W. B. Barnard, Philadelphia; Ellis L. Orvis, Bellefonte.

HERNDON, PA.—The Mahoney-Mahantango Telephone Company, of Herndon, has been incorporated with a capital stock of $20,000.

MAHANOY, Pa.—The Mahanoy & Mahantango Telephone Company has been incorporated with a capital stock of $20,000. Treasurer, I. B. Tressler, Mahanoy. Directors: Chas. Fritz, Treverton; David Wilhour, Mandata; E. R. Reitz, Rebuck; E. S. Stroub, Herndon; I. B. Tressler, Mahanoy; E. W. Dockey, Pillow; John Tressler, Urban; W. C. Leitzel, Klingerstown; C. R. Kehler, J. E. Kehler, Kehler; J. F. Brosius, Dalmantia; W. P. Zartman, Dornsife.

PITTSBURGH, PA.—The Allegheny Valley Telephone Company has been incorporated with a capital stock of $5,000. Treasurer, A. C. Boerner, Coudersport. Directors: A. C. Boerner, F. A. Stebbins, Fred. C. Leonard, C. A. Stebbins, A. F. Woods, Coudersport.

STAFFORD COURT HOUSE, VA.—The Toluca & Fredericksburg Telephone Company has been incorporated with a capital stock of from $1,500 to $5,000. The incorporators are: R. A. Moncure, Hugh Adie, T. G. Waller, T. J. Moore and Wesley Knight.

PINE CITY, WASH.—The Interstate Telephone and Telegraph Company has filed articles of incorporation with a capital stock of $5,000. The officers are as follows: J. J. Stephens, of Thornton, president; Nelson Howard, of Thornton, treasurer, and Dr. T. A. Swain, of Pine City, secretary and general manager.

UNION GROVE, WIS.—The Union Grove and Paris Telephone Company has been incorporated with a capital stock of $2,000 by the following: Henry Baens, O. T. Graham and C. E. Bartholfe.

PERSONAL.

E. D. CHILDRESS, foreman at Clinton, Ill., for the Farm & City Telephone Company for three years, has been promoted to manager of the Farmer City district.

WILFORD CONLEY has been appointed manager of the local company at West Bend, Iowa.

G. L. STERNS has been elected general manager of the Enterprise Telephone Company at Piperstone, Minn.

H. G. SLATER has been appointed by the Citizens' Telephone Company, Oshkosh, Wis., manager for the ensuing year. Mr. Slater now has charge of the Independent exchange at New London, Weyauwega, Waupaca and Sheridan and connecting toll lines.

R. B. WATSON has been appointed manager for the Michigan State Telephone Company at Detroit, succeeding G. S. Johnson, who will take another position.

Digitized by Google

MISCELLANEOUS.

DIXON, ILL.—The Lee County Telephone Company will move into larger quarters and will construct an underground system.

SPRINGFIELD, ILL.—The Illinois Central Railroad has completed its telephone line between Clinton and Springfield.

ATTICA, IND.—A new switchboard is being installed at West Lebanon.

SOUTH BEND, IND.—The forthcoming supplementary directory of the South Bend Home Telephone Company will show 300 new subscribers in the city and county.

SOUTH BEND, IND.—The last shipment of cables for the $30,000 contract for extensions has been received and will be installed as rapidly as possible. It has been delayed by fire in the factory.

SIOUX CITY, IOWA.—The Payette Construction Company, of Sioux City, has secured the contract for the erection of the Sioux City Telephone Company building at $19,419.

LEXINGTON, KY.—The Fayette Home Telephone Company has recently built a toll line to Georgetown, Ky., and also reconstructed its exchanges at Midway and Versailles, making them metallic, with long distance instruments.

BOSTON, MASS.—The July instrument statement of the American Telephone and Telegraph Company shows total of instruments in use of 2,080,758.

CAMBRIDGE, MINN.—The Twin City Telephone Company's exchange in this town was damaged by lightning recently.

LAKE BENTON, MINN.—Permits have been granted the Lincoln County Telephone Company to build and operate exchanges at Hendricks and Ivanhoe, and to build toll lines between those points. Construction will be started at once.

GEORGETOWN, N. D.—The Red River Telephone Company has connected with the local system giving service to Moorehead and Fargo.

HOOSICK FALLS, N. Y.—Plans have been prepared for the new Automatic Telephone Exchange building. The building will be of brick, two stories in height with basement, and will occupy a ground space of twenty-two by sixty-eight feet.

CINCINNATI, OHIO.—The subscribers in Elmwood Place, St. Bernard and Carthage are rebelling against a new rate schedule enforced by the Cincinnati & Suburban Telephone Company.

McCONNELLSVILLE, OHIO.—The new directory of the Home Telephone Company shows a total of 986 subscribers in McConnellsville and the surrounding country.

CENTER HALL, PA.—The organization of a local telephone company is assured in Union County. The patrons will have the use of the territory covered by Union County and Milton, with a five-cent rate to Sunbury over the Bell lines.

PITTSBURG, PA.—Street-car telephones, over which crews or passengers may converse at any point reached by telephone, were installed on the Charleroi division of the Pittsburg Railway Company recently.

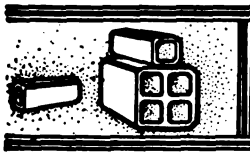
RACINE, WIS.—The Badger Telephone Company has secured right of way for a long distance line from here to the Mississippi near Monroe.

UNDERGROUND.

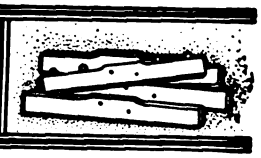
CARTHAGE, MO.—The Home Telephone Company is putting some of its wires underground.

BINGHAMTON, N. Y.—The York State Telephone Company is constructing an underground conduit system in this city.

NEWBURGH, N. Y.—The Colonial Telephone Company will lay 16,700 feet of new underground cable, some of which is 400-pair.



New Construction in the Field



TUSCON, ARIZ.—C. W. Hinchcliffe, of Tuscon, manager of the Arizona Telephone Company, is seeking to extend his telephone line to San Diego, Cal., and will probably purchase the system owned by W. F. Holt, of San Diego.

SOUTH McALESTER, I. T.—The Schooler Brothers' Telephone Company will begin the construction of a new telephone system in South McAlester in the near future. The system will cost $50,000, and will be built on the conduit underground system.

DES MOINES, IOWA.—The Mutual Telephone Company is installing a new switchboard in its new building. This work will be completed by November 1st.

GIBSLAND, LA.—The North Louisiana Telephone and Telegraph Company has received a carload of wire to be used in the construction of a metallic circuit telephone line between here and McNeil, Ark., and Natchitoches.

PADUCAH, KY.—The People's Independent Telephone Company is preparing to extend construction on local exchange at Salem and will construct several new lines.

PRESQUE ISLE, ME.—The Arrostook Farmers' Telephone Company will build a line to Mapleton and Castle Hill, and extend lines to Fort Fairfield and Caribou.

BOTTINEAU, MINN.—A rural line is to be run fourteen miles into the country, southeast from here.

BRICELYN, MINN.—The Bricelyn Mutual Telephone Company is extending its system to connect with the farmers' lines in the surrounding country.

MALACA, MINN.—A telephone line will be built from this town to Mille Lacs Lake.

KANSAS CITY, MO.—The Missouri & Kansas Telephone Company has just ordered fifty tons of copper wire and two new switchboards, and will spend something like $130,000 in reconstructing its exchange in St. Joseph.

LAMONTE, MO.—A number of citizens of Lamonte held a meeting recently to discuss plans for the organization of a local telephone company for operating both city and rural telephones, with central office located in Lamonte. As a result of the meeting a new company will be formed with a capital of $10,000.

MIAMI, MO.—The Saline County Telephone Company proposes to reconstruct its exchange in this city.

HASTINGS, NEB.—The Hastings Independent Telephone Company is making preparations to erect a $10,000 brick building. The work of excavating will be started within a few weeks. The building will be erected expressly for the Independent Telephone Company.

ST. JOHNS, N. B.—The Central Telephone Company has purchased the St. Martins Telephone Company. It is now erecting an extension through part of Kings County and the company, it is expected, will soon make application to the city council of St. Johns for a local franchise.

BLAIRSTOWN, N. J.—A company is being formed to build a telephone line from Blairstown to Flatrockville across Pahaquarry township.

RIVERSIDE, N. J.—The Standard Telephone Company, of Philadelphia, it is said will spend $5,000 in Riverside improving the exchange.

EDMESTON, N. Y.—The Wharton Valley Telephone Company is making preparations to extend its line down the valley to New Berlin.

HAMBURG, N. Y.—The Frontier Telephone Company completed its line to Eden recently, and the Eden Telephone Company is now utilizing its lines to connect with Buffalo and adjoining towns. The Eden Company has upwards of eighty patrons, which extends through Eden Valley. The Inter-Ocean Telephone Company is now building a line to North Collins and Langford, which will be completed within a fortnight.

WHITNEY'S POINT, N. Y.—The Centre Lisle Telephone Company is building two new lines.

FARGO, N. D.—The Red River Telephone Company is pushing the work of extending their lines in Clay and Cass counties. The telephones at Georgetown were connected with the system recently, and that village can now be reached by all subscribers in Fargo and Moorhead.

DOYLESTOWN, PA.—The Standard Telephone Company has opened a new direct line to Philadelphia. A new switchboard is being built, and when installed will give the subscribers of Doylestown as good service as any.

JOANNA, PA.—The Conestoga Telephone Company, at a meeting held recently, decided on a new switchboard for the Joanna exchange.

JOHNSTOWN, PA.—The Economy Telephone Company, an organization of farmers living in Elklick, Greenville, Larimer, Summit and Brothersvalley townships, will establish an exchange in Somerset.

NEW HOLLAND, PA.—The Enterprise Telephone Company will move its exchange into larger quarters. A new switchboard will be installed, also some aerial cable in the business part of the city.

BRINTON, S. D.—The Social Telephone Line, of Newark, is to run in a line and establish an exchange here.

SHERMAN, TEX.—A. L. Hills, district superintendent of the Phœnix Telephone Company, with headquarters at Houston, has perfected arrangements for the extension of the company's line from Bonham to Sherman, connecting with Dennison through the Grayson County Telephone Company's lines. It is the intention of the company to extend the line a little later from Bells to McKinney.

BELLINGHAM, WASH.—The lines of the British-Columbia Telephone Company from Bellingham to Vancouver Island are all completed with the exception of laying the submarine cable.

SEATTLE, WASH.—The Independent Telephone Company has connected its lines with Vishon Island and will have the line in service by October 1st. This line will give Seattle long distance connection with all the places in the vicinity.

TRADE NOTES

THE T. AND A. SELECTIVE CALL COMPANY, of Geneseo, Ill., has moved into much larger quarters, which became necessary on account of the larger orders on hand. It hopes to be able to keep up with them now, and will use every effort to that purpose.

THE CENTURY TELEPHONE CONSTRUCTION COMPANY has received a contract for constructing the entire plant for the Holley Telephone Company, in Holley, N. Y., including all apparatus for a common battery system. The company also reports an exceptionally busy summer, especially in its telephones equipped with the new Century Platinum Transmitter.

THE WILLIAMS TELEPHONE AND SUPPLY COMPANY, of Cleveland, Ohio, reports a decided improvement in trade conditions during the past month. Its recent removal into new and better quarters, with equipment which enables it to turn out the very best quality of goods in the least possible time, is already beginning to bear fruit.

F. B. COOK, of 240 W. Lake street, Chicago, Ill., has placed on the market a type of guy clamp that has several points of merit. This clamp is known as the "Universal," and is claimed by the manufacturer to be the strongest, simplest and cheapest made. It is manufactured in three sizes, for one, two and three bolts, and fits all sizes of strands commonly used, from three-sixteenths to one-half inch. Sizes larger than one-half inch are special.

W. N. MATTHEWS & BRO., Carleton Building, St. Louis, Mo., are distributing a novel folder entitled "Burial Expenses." This folder deals with the Stombaugh Guy Anchor, of which this company is the sole distributor. The circular states that the expenses of burying a "dead man" has prevented many a man from properly guying poles, fences, etc. The funeral expenses of the Stombaugh guy anchor are so small that the same men are burying them, because they know they will hold better than the "dead man." The circular includes descriptive matter and price lists and will be forwarded to all interested upon request.

THE AMERICAN CONDUIT COMPANY, Manhattan Building, Chicago, has just been awarded the contract by the electrical commission of Baltimore for a quarter of a million feet of bituminized fiber conduit. This contract was awarded after a series of exhaustive tests and investigations, which forms another important link in the chain of evidence favorable to bituminized fiber conduit for underground construction.

THE BAIRD MANUFACTURING COMPANY, of Chicago, is pushing the sale of its portable restaurant pay-stations, which are finding great favor among large telephone companies. A business man can, during lunch, call up his office or attend to other business matters with the greatest ease. The sale for this class of instrument is constantly increasing.

THE STERLING ELECTRIC COMPANY, of Lafayette, Ind., reports that its four-party selective equipment is gaining popularity daily. It has just completed shipments to Springville, N. Y.; Cooperstown, N. Y.; Meadville, Pa.; Warren, Pa.; Conneaut, Pa.; Cedar Rapids, Iowa; Chillicothe, Ohio; Louisiana, Mo.; Pittsburg, Kansas; Hudson, N. Y., and Lorain, Ohio.

THE AMERICAN STEEL AND WIRE COMPANY, of Chicago, San Francisco, New York, Denver and Worcester, has issued a price list of steel and copper wire on spools. This type of wire is made in all gauges from 16 to 36, and steel hair wire from 24 to 38 gauge. The steel wire is made up both bright and tinned annealed. The prices are per dozen spools, the spools being quarter, half and one-pound and one-ounce capacity.

HUBBARD AND CO., of Pittsburgh, Pa., wish to call the attention of the trade to its all-iron pole seats. These seats are made in the most substantial manner, the rim and braces being of angle iron, and the cross bars of stiff steel, solidly riveted to the rim. They are finished either japanned or black. Prices upon application. This firm also manufactures braces, pole steps, anchor rods, etc.

THE S. H. COUCH CO., of Boston, reports a steady demand for its No. 12 type of telephone. This set particularly pleases the construction man, as it is designed so as to make connecting a pleasure. Bulletin 6 explains in detail, free upon application.

THE CONTROLLER COMPANY OF AMERICA, 1061 Monadnock Building, Chicago, reports a good August business. Its factory in Chicago has been running a night force to keep up with the demand for controllers. A large shipment has just been made to the Kinlock Telephone Company for use on the World's Fair grounds, in addition to those that have been doing heavy service all this summer.

THE F. BISSELL COMPANY, Toledo, Ohio, reports an increased demand for its "Security" conduit rods. These conduit rods were recently put through some very severe tests by the Home Telephone Company, Toledo, Ohio, and the results were highly gratifying to the manufacturers. Besides being low in price, they possess qualities which make them the most desirable rods on the market. Light in weight, quickly jointed and unjointed, without slack at joints, yet rigid, and will not buckle or jam under pressure. Made in thirty-six and forty-eight-inch lengths; special lengths to order.

THE BAIRD MANUFACTURING COMPANY, 4 Michigan street, Chicago, maker of Baird Telephone Pay Stations, has brought out a new "Permanent Adjustment Transmitter Arm" which has merits of its own. As indicated by its name, the friction bearing will never require adjustment, either by the telephone assembler or patron of the telephone company. There are no nickeled parts to tarnish, rust or become defaced by adjustment. These arms are beautifully finished and striped, and should find a ready sale.

THE INTERNATIONAL TELEPHONE MANUFACTURING COMPANY, of Chicago, has recently installed a complete telephone plant connecting the various towns in central Wisconsin, and offices along the lines of the Green Bay-Kaukauna Interurban Railway System and the Fox River Valley Electric Railway and Power Company, recently built by the Knox Construction Company, Chicago. The telephone plant consists of an "International" self-restoring drop switchboard located at the main offices of the electric company, with long-distance bridging telephones at every branch of the system.

THE NATIONAL TOLL TICKET COMPANY is the new name just adopted by the firm of Gildart Brothers, Albion, Michigan, who have become well known to the telephone fraternity by means of their advertising in the columns of the AMERICAN TELEPHONE JOURNAL. This firm announces that its unanticipated success during the past months in the manufacture and sale of toll tickets and other printed telephone accessories, has convinced them of their right to the name they have chosen, which is printed at the head of this article. The new catalog showing twelve forms of toll tickets, a trouble ticket, and a few other attractive samples, is just out of the press, and may be had for the asking, together with an instructive leaflet, "How to Keep Toll Tickets," written by an operator of experience, which contains some valuable hints on keeping a record of every call, without any great loss of time. The National Toll Ticket is composed of a firm of enterprising young men, who are making a study of the needs of the independent telephone field in their line, and bringing forward some good results. The JOURNAL takes pleasure in introducing them to its readers. See their advertisement on page 16.

WANTED

Advertisements under this head, 25 cents for 25 words or less for each insertion. Prepaid.

WANTED you to know that I can locate your cable troubles. Charges moderate. Address C. E. NICHOLAS, Columbus, Ohio. 226

WANTED—Position by telephone engineer, capable of taking charge of plant and giving good service to subscribers and dividends to stockholders. Address, F. C. Woods, 665 Wells street, Chicago, Ill. 231

WANTED—Second-hand generators and ringers in good condition; give make, general condition and price asked. Address Box 223, AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 223

WANTED—Good mechanical draughtsman; must be perfectly familiar with telephone work. Address Box 243, AMERICAN TELEPHONE JOURNAL, 116 Nassau St., New York City. 243

POSITION wanted by competent telephone man as manager of magneto system. Experience in construction, operating and manufacturing. Best references. Prefers Middle West. Address Box 237, AMERICAN TELEPHONE JOURNAL, 116 Nassau Street, New York City. 237

FIRST-CLASS WIRE CHIEF desires position with large Independent telephone company. Can furnish the best of reference. Address Box 241, AMERICAN TELEPHONE JOURNAL, 116 Nassau Street, New York City. 241

COMPETENT telephone man desires position as manager; can furnish first-class reference as to ability and honesty. Address Box 240, AMERICAN TELEPHONE JOURNAL, 116 Nassau Street, New York City. 240

WANTED—Bright young man of good appearance, who understands thoroughly technical telephony. One who has worked in the field preferred. Must be able to write descriptive booklets on telephone apparatus. Exceptional prospects for the right man. Address Box 242, care of THE AMERICAN TELEPHONE JOURNAL, New York City. 242

POSITION WANTED—As manager or superintendent of telephone company; have had seven years' practical experience in all branches of the business. Address Box 247, AMERICAN TELEPHONE JOURNAL, 116 Nassau Street, New York City. 247

WANTED—Wire chief for central energy exchange in Central Indiana. Must be thoroughly experienced in switchboard work and capable of handling trouble men. Address Box 244, AMERICAN TELEPHONE JOURNAL, 116 Nassau Street, New York City. 244

WANTED—Two experienced telephone inspectors for central energy plant in Central Indiana. Address Box 245, AMERICAN TELEPHONE JOURNAL, 116 Nassau Street, New York City. 245

WANTED—Store-room keeper. Must be capable of repairing all kinds of central energy telephones and keep track of stock. State experience and salary expected. Address Box 246, AMERICAN TELEPHONE JOURNAL, 116 Nassau Street, New York City. 246

POSITION WANTED by a competent telephone man as manager of magneto system. Experienced in construction, operating and manufacturing. Best references. Middle West preferred. Address, Box 237, AMERICAN TELEPHONE JOURNAL, 116 Nassau Street, New York City. 237

WANTED.—At half value, fifty first-class second-hand compact series telephones (magneto) from some independent company that has changed to common battery. Must be from one of the best manufacturers. Address, Box 238, AMERICAN TELEPHONE JOURNAL, 116 Nassau Street, New York City. 238

WANTED TO SELL.—A telephone system operating in eight counties in a western State, with five small exchanges. Good city connections and a first-class investment. Easy terms to the right party. Address, Box 239, AMERICAN TELEPHONE JOURNAL, 116 Nassau Street, New York City. 239

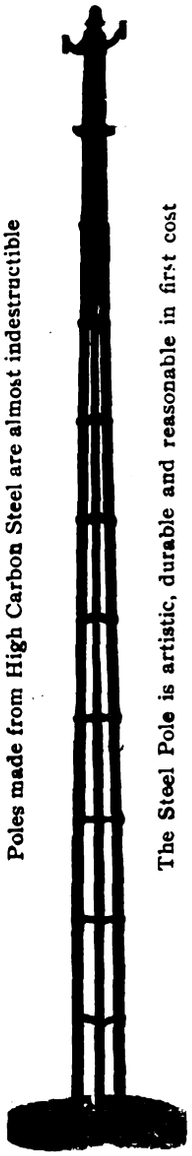
The Open-Wireless Telephone Plant

is an all-cable plant; that is it has no open wire (bare wire) or cross arms, and when supported on steel poles

DEPRECIATION IS ALMOST ELIMINATED; MAINTENANCE REDUCED TO A MINIMUM



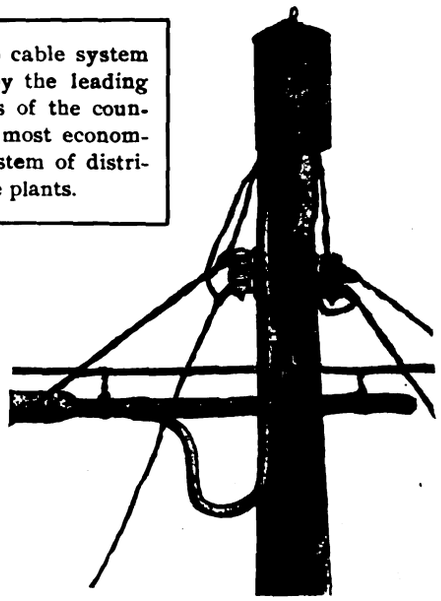
Poles made from High Carbon Steel are almost indestructible

The Steel Pole is artistic, durable and reasonable in first cost

POLE OF THE FUTURE

No poles to rot.
No cross arms to rot.
No glass insulators to break.
No crossed wires to interfere with service.
Trees do not interfere.
Sleet storms lose their terror.
No unsightly cross arms and wires on the streets.
No bare wires to break and fall on electric light wire and kill some one passing by.

The multiple tap cable system is acknowledged by the leading telephone engineers of the country to be by far the most economical and durable system of distribution for telephone plants.



THE SYSTEM OF THE FUTURE

The undersigned is a pioneer in the multiple cable distribution and makes a specialty of

Planning Cable Layouts
Multiple Cable Distribution
Equipping for Party Lines
Rate Raising, Etc., Etc.
Plans, Specifications and Supervision of Installation of Complete Telephone Plants

WILL GUARANTEE TO INCREASE THE DIVIDENDS IN 99 TELEPHONE PLANTS OUT OF EVERY 100

Engineering, constructing and putting plants on a dividend-paying basis a specialty.

There are many serious mistakes made in the selection of apparatus, construction and maintenance of telephone plants due to lack of experience.

There are many leak holes in a telephone plant unless properly watched.

With proper co-operation on part of owners of telephone plants, I will guarantee to make any Telephone Plant pay dividends or increase your present earnings. Can refer you to a number of telephone plants where I have saved thousands of dollars in first cost of the plant, increased the earnings, improved the service, decreased the operating expenses by installing proper apparatus in the proper way and properly organising the working force. Can furnish expert engineer, wire chief, auditor, solicitor, chief operator, each a specialist in his line.

HOW DO YOU TEST FOR TROUBLES?

PROBABLY you have an old magneto bell rigged up in some fashion. It will show in a general way a short circuit, but you know it isn't accurate or reliable. Why don't you get our special volt-ammeter for resistance measurements?

With this instrument and a few cells of battery you can detect a short circuit and tell how bad it is. You can tell whether the receiver is off the hook or whether there is a wire across the lines. You can detect a ground and measure any ordinary resistance. In fact, when a line gets in trouble, by throwing a key you can connect in circuit the voltmeter and in less than a minute you will have determined the nature of the fault. When the troubleman goes out he will know exactly what to look for. This saves time, and therefore money.

The apparatus and methods are very simple. We will explain it all to you. Our instruments don't cost nearly as much as you think. Write us about them.

The 1900 Dry Battery

THE most needed quality is reliability. No one wants a battery that will respond all right for a week or ten days then "suddenly go out of business." Another requirement is that it shall continue "strong" during its life. These two requirements besides many others are characteristics of

1900 BATTERIES

We guarantee them not to freeze, leak or break; we warrant them to work with a strong, steady current during their life (anywhere from six to eighteen months).

They are compact, always ready. They are better than wet batteries—no slop, no repairs, no breakage. Any one can replace a worn out one at a moment's notice. They can be carried anywhere—always ready for instant use.

Ericsson Four Party Line System

For simplicity, satisfactory service and good results, this system takes the lead. The line is perfectly balanced. Each subscriber is called without a chance of disturbing the others. One party can call central without disturbing the others on the line. Absolutely non-interfering. Extremely simple to install, to maintain and to operate. Few changes or additions necessary at the switchboards. Ask for particulars with prices, etc.

We supply party line telephones for common return or metallic circuits, either two or four on a line.

We manufacture a large line of telephones, switchboards and specialties.

Our wall or desk, sets, as illustrated, are growing in popular favor because they are so convenient. Price reasonable.

HOW DO YOU TEST FOR TROUBLES?

PROBABLY you have an old magneto bell rigged up in some fashion. It will show in a general way a short circuit, but you know it isn't accurate or reliable. Why don't you get our special volt-ammeter for resistance measurements?

With this instrument and a few cells of battery you can detect a short circuit and tell how bad it is. You can tell whether the receiver is off the hook or whether there is a wire across the lines. You can detect a ground and measure any ordinary resistance. In fact, when a line gets in trouble, by throwing a key you can connect in circuit the voltmeter and in less than a minute you will have determined the nature of the fault. When the troubleman goes out he will know exactly what to look for. This saves time, and therefore money.

The apparatus and methods are very simple. We will explain it all to you. Our instruments don't cost nearly as much as you think. Write us about them.

Do You Use This Kind of Booth?

An Illinois weekly paper recently contained the illuminating information that one of the village lights "is spending his vacation at carpentering. He built a booth for the telephone company, which was very artistic." Meaning, probably, that the telephone company is artistic, for we don't believe such a booth could be.

We have had years of experience in designing artistic, serviceable, sound-proof booths.

Don't order from a carpenter.

Write us for cheaper prices and better booths.

Cyclopedia of Applied Electricity

A Practical Guide for Electricians, Mechanics, Engineering Students and All Persons Interested in Electricity ... ...

Special attention is paid to Telephone Work, one whole volume being devoted to this important branch of Electricity. The whole work, however, is of exceptional value to Telephone Men, fully explaining the Principles of Magnetic Induction, Calculation, Tests, Measurements, Common Battery System, etc. Prof. Crocker's treatises on Dynamo-Electric Machinery and Storage Batteries bear the stamp of highest authority. The whole field of telephone practice is thoroughly covered from the fundamental principles of Electricity to the complete installation and operation of both city and rural exchanges. The editor of The American Telephone Journal in referring to merely one section of the work says:

"The section on Storage Batteries by Prof. Crocker of Columbia University, strikes us as being particularly good. It gives just the sort of storage battery information and tells it in just the sort of way that will reach the practical telephone man, who should at least have a good idea of this appliance which is now so common in these days of central energy."

Five Volumes—2500 Pages—size of pages 8x10 inches, fully indexed. Handsomely and durably bound in buckram, profusely illustrated with 2000 diagrams, full-page plates, sections, tables, formulae, etc. Invaluable alike to the expert electrician and the apprentice. Every section written by an acknowledged authority. Prepared especially for practical, every-day use. A text-book and a reference work combined, as every volume is followed with a carefully prepared list of practical test questions to impress the important points on the reader's mind.

FREE A limited number of introductory sets will be sent for examination as soon as received from the press. We are printing an edition for our own use. By increasing the edition we can reduce the cost of manufacture. We are willing to share this saving with those who order ***now*** for future delivery. The regular price is $25 00. **We will accept reservation orders until the books go to press, at $12.50—just half the regular price.** The books will be sent by express, prepaid, on approval, and may be returned at our expense if not in every way satisfactory. **Those desiring to have a set reserved at the reduced price** must send $2.50 with their application as an evidence of good faith. This amount will be credited on the books, or returned if they are not kept. No further payments need be made until December 1st, when payment of balance ($10.00). at the rate of $2.00 per month must begin. No reservations can be made at the present advance sale price ($12.50) after the edition goes to press.

Some of the Writers

PROF. F. B. CROCKER, head of Department of Electrical Engineering, **Columbia University:** author of the sections on Storage Batteries and Management of Dynamo-Electric Machinery.

PROF. WILLIAM ESTY, head of the Department of Electrical Engineering, **Lehigh University:** author of the section on Alternating Current Machinery.

WILLIAM BOYRER, Telephone Expert and Consulting Engineer.

H. C. CUSHING, Jr., Wiring Expert and Consulting Engineer: author of the section on Wiring for Light and Power.

PROF. DUGALD C. JACKSON, Collaborator with **PROF. GEORGE C. SHAAD, University of Wisconsin:** author of sections on Power Transmission, Electric Lighting and Central Stations.

J. R. CRAVATH, Western Editor of the **Street Railway Journal,** author of the section on Street Railways.

PROF. LOUIS DERR, Mass. Institute of Technology;

CHAS. THOM, Chief of **Quadruplex Department Western Union Telegraph Co.,** author of section on Telegraphy, and others.

Partial Table of Contents

PART I.—Static and Dynamic Electricity—Primary Batteries—Ohm's Law—Wire Calculations—Electrical Measurements—Wiring for Light and Power—Electric Telegraph, including the Duplex and Quadruplex.

PART II.—Theory of Dynamo-Electric Machinery—Design and Construction of Dynamos and Motors—Types of Machines—Storage Batteries, including Theory, Management and Types—Testing Efficiency.

PART III.—Incandescent and Arc Lighting—Electric Railways, including Car Wiring, Line Construction, Third Rail and Multiple Unit System—Management of Dynamo-Electric Machinery—Power Station Work—High Tension—Transmission.

PART IV.—Theory of Alternating Currents—Construction, Types and Operation of Alternators, Transformers, Induction Motors, Synchronous Motors and Rotary Converters.

PART V.—The Telephone—**Telephone Lines**—Circuits—Distribution—Line Construction—Distributing Points—Submarine Cable Lines—Cross Talk—Pupin's Load Coils—**Telephone Exchange**—Switchboards—Exchange Wiring—**Operation and Maintenance** Systems—Local Calls—Trunk Calls—Toll Boards and Lines—Long Distance Switchboards—Direct and Party Lines—Code Signalling—B. W. C System—Private Branch Exchanges—**Common Battery System**—Testing and Clearing Trouble—Wire Chief's Desk—Testing Circuits and Apparatus—Testing New Cables—Cutting into Service—Locating Faults—Replacing Defective Sections.

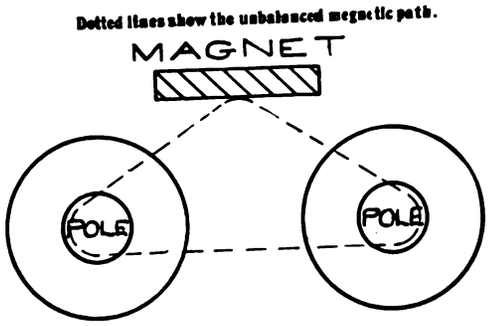
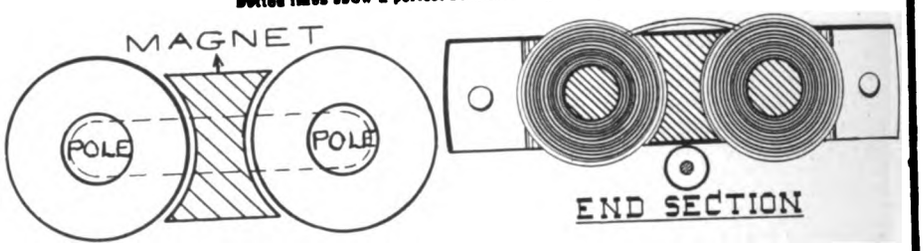
Magnetic Field of Old Style Ringer with Magnet On Side.

Dotted lines show the unbalanced magnetic path.



Magnetic Field of Swedish-American New Patented Ringer with Magnet in Center.

Dotted lines show a perfect balanced magnetic path.



THE illustrations clearly demonstrate that **all** ringer movements heretofore have been manufactured on the wrong principle. It remained for the Swedish-American Telephone Company to devise and place on the market a perfectly balanced ringer movement; a ringer with a perfectly balanced magnetic field. **All** other ringers have the magnet on one side of the coils, thereby dissipating a good percentage of the energy, consequently the bells do not ring as loud as they should, nor will as many operate satisfactorily on one line, as properly balanced ringers ought to. The make-up of this new ringer **not** only increases the efficiency, but permits of the most compact and durable construction; fewer parts; more positive adjustment and will operate more satisfactorily for a longer period and at less cost for maintenance than **any other. All** Swedish-American Telephones are equipped with this new ringer, placing our apparatus one notch higher in the art of Telephony and ahead of **all** other makes, either Bell or Independent.

This new invention is fully covered by United States Letters Patent Number **733225**.

VOLUME 10 SATURDAY, SEPTEMBER 24, 1904 NUMBER 13

NATIONAL CONVENTION MEETING AT ST. LOUIS

(By Telegraph.)

NEW life has been infused into the National Telephone Association. At the annual convention held at St. Louis on Sept. 21, 22, 23 and 24 the name was changed from the Independent Telephone Association of the United States to the National Telephone Association. A new constitution and by-laws were adopted and a permanent committee appointed to reorganize the association. This committee, which is mentioned elsewhere in this report, was authorized and directed to effect a national organization on the line of the "Ohio Idea." It was decided to have a salaried assistant secretary and assistant treasurer to give up their entire time to association business. The association will have a permanent national headquarters when the organization is effected, and it will be its duty to make the injury or welfare of one company composing the membership the concern of all. The idea is to put Independents on a footing where they may present a united front against the Bell, so that solid organization may be opposed against solid organization.

Leading Features of the New Constitution.

The name—The National Telephone Association of America.

The object—To defend members by moral effort, co-operation, and other means.

Officers—Not less than fifteen trustees, but there must be one for each State affiliated with the organization. A President, First and Second Vice-President, a Secretary and a Treasurer.

Committees—Executive Committee of nine, including the President, to be appointed by the President. Litigation and Legislation Committee of five.

Meetings—Annual and also such special meetings as Executive Committee may direct.

Meetings—Annual and also such special meetings as or individual company representing not less than 500 telephones or 500 miles of pole lines shall be entitled to membership on application to and approval of Executive Committee.

Delegates—At annual meetings one for each 10,000 telephones or miles of pole lines or fraction thereof in any one district. Delegates representing less than 10,000 telephones or miles of pole lines to have only part vote in proportion to number they represent.

Quorum—A majority of all members present at meetings.

The annual dues shall not exceed one cent per telephone or one cent per mile of pole line.

Only Independent interests are eligible to membership.

Any company or body ceasing to be Independent or any officer ceasing to be Independent must withdraw. Where there is a State organization representing a majority of Independent interests in that State, those seeking admission must be affiliated with the State organization.

Manufacturers are not eligible to membership.

Members must be elected by ballot.

The New Officers

A nominating committee, composed of E. B. Fisher, Maxine Reber and George W. Beers, was appointed. They presented the names of the following to serve as officials of the association during the ensuing year:

President—J. B. Hoge, of Ohio.

First Vice-President—Breckenridge Jones, of Missouri.

Second Vice-President—William Flynn, of Pennsylvania.

Treasurer—Hugh Dougherty, of Indiana.

Secretary—A. L. Tetu, of Kentucky.

These officers were unanimously elected by the association.

The attendance was very large and every delegate present took a personal interest in the meeting, which resulted in the meeting-room being crowded for every session.

The convention adopted by rising vote resolutions of sympathy for Judge J. M. Thomas, former president of the association, who is now fatally ill. Greetings were sent to him by wire.

Edward E. Clement then read an interesting paper on the "Patent Situation." He said an average of thirty patents were being issued monthly. The work has increased to such an extent that it now takes four examiners in this special class. A total of 4,298 telephone patents have been issued to date, 3,798 of which are in the telephone class proper and 500 relating to appliances intimately connected with telephone subjects. About 24,000 claims are in force in telephone patents that must be carefully watched to prevent infringements. Mr. Clement pointed out the special need of a close, active organization for protection in patent litigation and infringements. Although there are at present no large suits threatened, yet Mr. Clement believes that steps should be taken in case of an emergency. He read letters to him along this line from John C. Marble, president of the Home Telephone Company, of Los Angeles, Cal.; O. C. Snider, general manager of the Home Telephone Company, of Kansas City, Mo.; E. H. Moulton, president of the Twin City Telephone Company, of Minneapolis and St. Paul, and W. H. Barnard, vice-president of the United Telephone and Telegraph Company, of Philadelphia. All of these gentlemen strongly urged a national organization on advanced lines.

Organization Committee Report

At the conclusion of Mr. Clement's paper the committee on organization presented its report through Senator Kleine, advising that the national organization should be composed of delegates from each association on a basis of one delegate for each 10,000 telephones, and for long-distance companies one mile of toll lines to be classed as one telephone.

Digitized by Google

States not having organizations to be entitled to send delegates on the same basis by companies. Any company with less than 10,000 telephones to have the right to send a delegate, who shall have floor privileges at all national conventions and vote in proportion to number of telephones controlled by his company. Each telephone and supply manufacturers to be entitled to one delegate on payment of the annual dues. Each telephone and pole line mile shall pay a tax of one cent to support the association. This report was unanimously adopted by the convention and the same committee appointed to take up the details and draw up a constitution.

On Thursday morning Frederick S. Dickson, president of the Cuyahoga Telephone Company, of Cleveland, Ohio, read the following paper, which was listened to with great interest:

HINTS TO INDEPENDENT COMPANIES*

By Frederick S. Dickson.

I AM in a measure in accord with our enemies when they declare that the telephone business is a natural monopoly and when they insist that there ought to be but one telephone system in a town. I say "ought," for the Bell Telephone Company being in possession of the field, "ought" have given good service at reasonable rates. By so doing competition would have been rendered practically impossible. Unfortunately for the people of this country, the Bell company never did give proper service nor furnish their service at reasonable rates until forced to do so by competition. When the Bell was in control of the field the service was uniformly bad, and moreover the field was not properly developed and no attention was paid to accommodating the public The Bell policy was to develop thickly settled quarters in large cities. It actually refused in every instance to run lines in sparsely settled sections. Its service was extended only to the thickly settled business portions of large communities. It refused absolutely to extend lines into the residence sections of the largest cities.

Even when the Independent companies entered these large cities the Bell waited until the Independent company began laying conduits and stretching cables before offering accomodation to residence sections. In Cleveland, Ohio, for instance, when the Cuyahoga Telephone Company entered the field the Bell company had only 4,200 telephones in service. The rate for a business telephone was $120 a year. At this rate business men of Cleveland were paying nearly 3 cents for each connection. Competition changed the conditions radically. The Bell company, under the stimulus of competition, increased its system to 16,000 telephones. Business charges were reduced to $84 per year so that a subscriber who had paid nearly 3 cents for a connection now pays a little more than one-half a cent for each possible connection. A party taking both telephones in Cleveland will pay at the highest business rates $156 a year. He will have at his disposal 28,000 possible connections. On this basis he would be paying less than six mills per year for each telephone to which he has access. Thus competition has reduced the cost of telephones to one-fifth of what it was before in Cleveland, and at the same time has resulted in a general improvement of the service.

However objectionable two telephones may be in view of these results, two telephones seem to be a necessity at the present time. Competition will continue to benefit the general public. Which company will be the victor is a question for the future and one that will be determined only by time. In my opinion local ownership will be a factor of prime importance. The more local stockholders there are in a telephone system the greater will be the advantage of that system. The Independent exchange should be owned and controlled by its own people. Such ownership insures better service and a local support with which foreign-owned corporations cannot for long compete.

But local ownership alone will not insure success. You have got to give better service than your rivals. Make your operators and other employees take an interest in making your service good. I am a firm believer in profit sharing with employees. If one wants more wages, let him work more, save more and earn more, and the profits earned will give him more. We have tried this plan in Cleveland with encouraging results for the past year and we propose to continue it for another year.

I am afraid that some of my friends are under the impression that the chief duty in life is to fight the Bell company. This is surely a mistake. Let us first please the telephone users and then we can please telephone investors with attractive dividends. Don't bother your heads about the Bell company until the Bell people get in your way. Then run over them.

I was introduced to President Fish, of the Bell company, shortly after I entered the telephone field. He told me that we could not possibly succeed in Cleveland. "We have let you people alone so far out there," said Mr. Fish, "but you can't expect us to ignore you much longer. When we are ready, we will simply crush your enterprise." In reply to this threat, I told President Fish the story of the man who had a reputation for being "d——d industrious while being licked."

I don't know that we have annoyed the Bell very much, but I do know that we have been "d——d industrious and 'aint' licked yet." Do you know that the Cuyahoga Telephone Company is actually giving better service in Cleveland and at less money than is the Bell? We have added over 3,000 telephones in Cleveland in the past five months and we are increasing right along at the rate of 700 per month.

Editors' Note: Abstract of paper read at the National Convention, St. Louis.

Manufacturers in the Association

A delegate brought up the question of whether manufacturers should be admitted to the association. This caused considerable discussion on the floor and afterwards in private conference. Thomas W. Finucane, of the Stromberg-Carlson Telephone Mfg. Co., was specially called on to give the manufacturers' side of the question. Mr. Finucane said that he was not present in his capacity as a manufacturer, but as a delegate of the Rochester Telephone Co., of Rochester, N. Y. Continuing, Mr. Finucane said: "Manufacturers, in my opinion, should not be eligible to membership in operators' organizations, either State or national. The operators should stand alone. Manufacturers should have an organization of their own."

This seemed to express the sentiments of most of the manufacturers present, and many urged Mr. Hoge as chairman to work along these lines in perfecting details. "Leave the manufacturers out," they said; "it will be for the best interests of the organizations."

Mr. McMeen Speaks

After this matter was disposed of, Samuel G. McMeen, of Chicago, read a strong paper entitled "Planning a Telephone System." He went into minute details in a masterly manner. This paper will be printed in full in our next issue, as it is a very interesting one. At the request of the chairman, Mr. Dwight Sapp, of Ohio, explained the "Ohio idea" on which it is proposed to model State and organization work. This idea follows closely the lines of the paper by Mr. Hoge, which is printed in this report. At the request of Mr. Hoge, Senator Flynn, of Pennsylvania, who is largely interested in the Pittsburg and Allegheny Telephone Company, made an address. Mr. Flynn said that the success of the organization's scheme depended upon the activity of the leaders. Paid officials of a high grade would be needed. They should be selected with great care and should get good pay.

Association Name Changed

Edward P. Baird, of Chicago, moved that the association's name be changed to National Independent Telephone Company, as the old name did not convey the proper idea. This was unanimously adopted by the association.

Digitized by Google

THE FIRST DAY'S SESSION

President Dougherty called the convention to order at 11 o'clock on Wednesday, the 21st. After a few introductory remarks, he introduced Professor Goldsborough, Chief of the Electrical Bureau of the Exposition, who in an appropriate speech welcomed the delegates in behalf of President Francis of the Louisiana Purchase Exposition.

President Dougherty's Address

President Dougherty then read an address, saying among other things: "There should be a fealty between Independent operators. Each should have the sympathy of all others. At present this does not prevail. In some instances one Independent company has tried to drag down another from jealous motives. By public criticisms and connivation with tax assessors they have sometimes taken away the business of another company and increased expense account to such a point that the weaker opponent has gone to the wall. These tactics have not been noticeable of late but it is generally understood that they have prevailed in some of the States."

Continuing, President Dougherty said: "We have reached a point where a better understanding must exist between operators. We must become more of one mind and therefore must become as one institution. Apparatus and construction should be better standardized, and we must take better care of the public. These criticisms, it must be understood, carry no reflection upon Independent operators, for, as a whole, no class of business men are more deserving, and as business promoters and managers none stand higher in the estimation of financiers. Independent securities have become a boon to investors, and as time goes on telephone bonds will become more and more staple until they will occupy the foremost place of all industrial securities. It is necessary that operators should join their energy and capital and thus prepare for better service both in exchanges and toll systems. At the present time too much stress cannot be laid upon necessity of action in respect to long-distance lines. Independent lines must reach out and connect with all the great cities so that it will be possible for one Independent company to reach any other Independent company no matter where situated."

Closer Co-operation the Key-Note

President Dougherty's address formed the keynote of the convention. The whole sum and substance of the matter is that closer co-operation and a more perfect organization is needed. A detailed plan to bring this about was presented in a paper read by Mr. J. B. Hoge, which will undoubtedly form a basis for re-organizing the National Association.

Needs of Telephone Engineering

A paper by Professor J. C. Kelsey, of Purdue University, was next read by the secretary. It was entitled, "What Telephone Engineering Needs." There was a time, said Professor Kelsey, when the profession of a telephone engineer was looked on as a joke, and there was a lot of truth in that. Under monopolistic control there was little advance, mainly from the reason that ideas were not wanted from the rank and file. Only a few men were thinking and they were overworked. Muzzled opportunities destroy incentive and lower the dignity of early telephone engineers; but they worked well. The greatest harvest which awaited the Independent methods of frankness and openness has been proved by the enormous strides which have taken place, until now the profession of telephone engineering has taken a front rank in the science of electricity.

National Association's Aid

In this particular department of Independent telephony the National Telephone Association has set a good example in that it has assisted in making public the various engineering problems which have thus been brought before the minds of thinking men, who have devised means to overcome the difficulties. Let us hope, continued Professor Kelsey, that all the interests engaged in Independent telephone engineering will realize the necessity of publicity in setting forth their problems so that the world may have a chance to applaud the telephone engineer. Telephony needs no aid at present but publicity to arise to a proper dignity.

Strengthen the Association

The paper by Mr. J. B. Hoge was read next, and brought about active discussion. Mr. Hoge made a strong argument for the reorganization of the association and the employing of salaried officers to carry on the work vigorously. In full his address was as follows:

THE VALUE OF ORGANIZATION

JAMES B. HOGE.

ORGANIZATION is the watchword of the twentieth century. There never was a time in the world's history when the subject of organization received so much attention as at present. It is generally conceded that proper organization is a good thing, but that in some cases its privileges are abused. However, that does not condemn organizations any more than the fact that laws are daily violated condemns the necessity of having national, State and municipal laws for the government of our people. The subject assigned me is one that is commanding the best thought of Independent telephone people to-day.

It is now about ten years since the first Independent telephone properties were put on an operating basis. Very few were put in successful operation until 1898, and comparatively few until 1896 and 1897.

The National Independent Telephone Association was organized in 1897 principally for the purpose of defending patent litigation that was then threatening the very foundation of the Independent movement. The way this association covered that field and protected the patents is now a matter of history and needs no explanation or defence.

The Independent telephone movement has grown beyond all expectation. The Bell Company had controlled the telephone situation more than seventeen years and had less than 300,000 telephones in operation. When the basic patents expired the American people only needed to be allowed the privilege of using the telephone, applying it to their business and social life in order to appreciate its full value. During the past ten years the Independents have installed more than 2,500,000 telephones, connected with their various systems throughout the United States. During the same time their competitor has many times doubled the number they had when the Independents were allowed to enter the field, so we find the telephone growth to-day is greater than that of any of the other public-serving corporations. The result has been that the Independent telephone companies have extended their systems from county-seat to county-seat and from center to center until to-day they are touching elbows with each other on practically every boundary line. Until the past three years they had but very limited long-distance service; to-day their long-distance service in many cases is equal to that of their competitor, and promises in a very short time to be in every way equal, if not superior, to their service. The Independent movement is made up largely of the most substantial and most active business interests of the country.

The leaders of the Independent movement have gone into the business from various other vocations, and the result has been that they have carried their former ideas as to bookkeeping, operating rules and regulations, from the banking, manufacturing, mercantile, transportation, gas and electric light business, into the telephone business. It is important and necessary to standardize rules and regulations, form of accounting, advertising methods, equipment and various other essentials, so that the different companies may be operated as a single property. It is

Digitized by Google

no more necessary to consolidate these local exchange properties in order to carry it out successfully than it would be to consolidate all the steam railroads, or electric railroads, in the United States in order to operate them successfully on a uniform basis. Several years ago the steam railroads adopted standard gauge of track, so that to-day practically every road in the United States has adopted the same. The locomotives and cars made in the various shops of this country are so thoroughly standarized that they can be operated successfully in trains with other cars and locomotives from one end of this country to the other. Brakes, couplings, etc., have been standardized so that there is no longer the necessity of telegraphing or writing to find out whether or not the equipment of this road or that road can be operated over the tracks of some other company. Rules and regulations governing the handling of passengers, baggage, etc., have all been standardized so that to-day through tickets are sold over the lines of the various companies, beggage is checked through, freight is billed through, and rates are quoted from one distant point to another. Schedules have been arranged so that trains connect with each other at terminal or junction points. Time for operating trains has been standardized, thus simplyfying the matter of traveling, making it more convenient for the public and less annoying to the operating companies.

The American Bankers' Association, who held their convention in New York City last week, have for the past fifteen years been working out a system for the banks of this country that has simplified the methods of handling their business, and at the same time have thrown around themselves by the enactment of proper laws and otherwise a number of safeguards that enables them to deal more cautiously with the very life-blood of our commercial and social welfare. A number of those most actively identified with the Independent telephone movement have been active on the committe of that association, working out economies and throwing around the association the safeguards mentioned.

During the past five or six months I have been in correspondence with various officers of a number of State associations, and find that in nearly every case they agree that the time is ripe for better organization. What we need to-day is uniformity of organization. There is no other business parallel to that of the Independent telephone companies. In Ohio a decision has recently been handed down by the Supreme Court of the State declaring that city councils have no right to regulate rates, which was of extreme importance to nearly all the operating companies, as in many cases the early franchises provided for rates that were too low to carry on the extensive business that the companies are now doing.

In practically every case the public recognizes that they are getting a more extended and better service than they expected at the time the franchise was granted and the early contracts entered into, and are therefore willing to sign new contracts at fair rates. However, the early franchises provided a means for the grandstand politicians and municipal reformers to start litigation against the various companies. This decision has therefore been most valuable to all Independent telephone companies, and especially to those in Ohio. If this suit had been inaugurated against some weak company and had been allowed to go by default, the results might have been most disastrous. With the proper kind of organization suits of this character will be fully protected.

In the post office fight last winter, which was fought vigorously by the Independent companies, there was a great deal of duplication in the way of letter-writing, personal interviews, etc., which with the proper kind of organization could have been taken care of successfully by having each State look after its own senators, and each district in the various States look after their own congressmen. In addition to this, the advantage of a strong organization would carry weight with the various legislative bodies, national and State, much greater than where taken up in a haphazard sort of way without proper organization.

During the past eight months we have reorganized our Ohio Association by dividing the State into nine districts. The State association has a president and nine vice-presidents, secretary, assistant secretary and treasurer, and an executive committee of four members besides the president, he being an *ex-officio* member. There is one vice-president from each district, and this vice-president is president of his district. Each district has an executive committee consisting of one representative from each county in the district. Hereafter our State association meeting will be a delegate body. Each district will elect one delegate to the State convention for each 1,000 telephones or fraction thereof they have represented by their district associations. A mile of long-distance toll line is counted as one telephone. In this way district meetings will be held quarterly or semi-annually so as to bring people with common interests together frequently to discuss subjects of special importance to the district.

In this way operating methods, rules and regulations, etc., can be standardized; meetings can be held without the loss of but very little time and at a nominal expense. The State Association will take up subjects of special importance to the Independent telephone interests of the entire State. We believe this plan is feasible and practicable for all the States in the Union to adopt. We believe it feasible and practicable to carry it a step farther, making an organization of the various State organizations, so that the various districts would elect one delegate annually to a general convention, and the State associations at their annual meetings would elect a sufficient number at large so as to give the State one representative for each 10,000 telephones or 10,000 miles of toll line they have represented in their State associations.

In that way the State delegations would be able to exchange ideas and to conduct their business on a uniform basis. Statistics can be accumulated and published that will be of special value to the Independent companies. By working the entire plan out on a basis of this kind the securities of the various companies will be strengthened. The equipment of the companies will be improved upon from time to time. The disposition of two companies to parallel lines or to compete with each other in any way will be minimized. The matter of adverse legislation, national or State, can be protected. This sort of an organization would be able to get the best results from their various business and political leaders.

This is not a new method of organization; it is applying a well-established and well-developed plan to our business. It is human nature to take pride in being part of a successful organization.

As a matter of practical illustration I wish to call attention to but two points, which I believe will explain themselves: First, the matter of toll station signs. Up to the present time almost every company has had their own ideas about the same, and the result is that any one of the operating managers here assembled would not know what to look for if he went into most any city 25 to 500 miles away from home. That being the case, how do you expect the traveling public to keep track of the different companies and different forms of toll signs? In June of this year I spent nearly three weeks here on the Fair Grounds, and I must frankly admit that it was much easier for me to locate a Bell pay station than it was the pay stations of our friends, the Kinlock Company, for the sole reason that I did not have to read the American Bell sign, but I did have to accustom myself to the Kinlock sign, which takes practice.

Operating rules and regulations must be standardized. Some time ago I undertook to carry on a long-distance conversation over three different companies' lines, all of which had different operating rules about monitoring lines, and the results were that our conversation was killed by the kindness of the various monitors.

In conclusion I desire to urge the importance of proper organization. We must draw a line to perfect the Independent system, and then cut to that line and the result will be most advantageous to all. First it will improve and simplify the service which benefits the patrons. Second it will reduce the operating and construction expense to a minimum, give greater stability to the securities, and be generally beneficial to all companies.

There is room for two telephone systems but not room for a third. With proper organization on the part of the Independent companies they will continue to be stronger than their opponent, and will receive their full share of the business on a fair and profitable basis.

President Simmons, of the Atlanta Telephone & Telegraph Co., of Atlanta, Ga., strongly urged carrying out Mr. Hoge's plan, and illustrated the need for effective organization by relating his experience. In one instance eight of his company's cables were ruined by wanton cutting, and depredations still continue.

Thomas Finucane, of the Stromberg-Carlson Telephone Manufacturing Co., of Rochester, N. Y., was then called upon to express an opinion. He said: "Ordinarily I don't believe in co-operative organization. But in this instance, if efficient men can be secured to guide it, the plans of the association as outlined in Mr. Hoge's paper would be good. To secure the right kind of men the right financial inducements would have to be offered, but I believe the association could well afford to pay for such men as could give their entire time and services to it."

Senator Kleine, of the Interstate Telephone Company of Pennsylvania, expressed decided approval of Mr. Hoge's plan. He said: "Only by efficient organization can the Independents be sure of drawing capital for extensions. The present system of the National Association is farcical."

Didn't Know of Convention.

"We in the East did not know there was to be a convention. Personally, I only learned about it in a roundabout way, and when I arrived in St. Louis there was no one to tell me where the Convention was to be held. This sort of system should be done away with. We should organize on regular lines and have a competent, salaried secretary to devote his entire time to the welfare of the association. With systematic organization to extend the powers and duties of the association, in a short while there would be no difficulty to find plenty of capital which at present is something almost impossible. There is no safer or more conservative investment than Independent telephone securities. They are much better than trolley securities. I know, because I am interested in both. In trolley systems careless employees may wipe out years of profits through one collision. No such possibility exists in telephony. I think that conditions are now ripe for closer organization. The old jealousies seem to have pretty well disappeared. Formerly we were afraid that we could not get enough territory. Now, most of us know that we have too much."

The Michigan Way.

E. B. Fisher, of the Citizens' Telephone Company of Grand Rapids, said: "Great benefits have come from closer organization in Michigan. Perfected traffic arrangements have done wonders to wipe out difficulties between connecting companies.

"Now," he continued, "we are ready to reach out and make agreements with neighboring States along the same lines. Need of organization is also necessary from a moral standpoint. A case in evidence is that of an Independent company of Michigan, having a capital of $100,000 and paying a dividend of 8 per cent., which made arrangements that brought it under the control of the Bell company. There was no need for this deal. The company was in a first-class condition and had no financial difficulties. Had we been organized in a central body when this occurred and looked squarely into each other's eyes this arrangement would never have been made."

An Organization Committee.

On a motion by Mr. Hoge and seconded by Mr. T. B. Lee, Pittsburg, Pa., chairman, the following committee was appointed to perfect plans of organization: J. B. Hoge, Cleveland, Ohio, Chairman; C. W. Kleine, of Pennsylvania; H. Linton Reber, St. Louis; J. B. Earl, Waco, Texas; E. B. Fisher, Grand Rapids, Mich.; Edward L. Barber, Toledo, Ohio, and Cyrus Huling, of Columbus, Ohio. The meeting then adjourned.

MANUFACTURERS AND SUPPLY DEALERS PRESENT

THE following is the list of manufacturers and supply dealers at the convention, together with their representatives:

The American Electric Telephone Company of Chicago was represented by P. C. Burns, J. G. Ihmsen and S. J. Baer.

President W. E. Doolittle, represented the Sterling Electric Co., of Lafayette, Ind.

Thomas W. Finucane, W. C. Stiger and J. D. Cracraft represented the Stromberg-Carlson Telephone Manufacturing Company of Chicago, Ill., and Rochester, N. Y.

The Crawfordsville Wire & Nail Co., Crawfordsville, Ind., was represented by R. Schweitzer.

The Swedish-American Telephone Co. of Chicago was represented by J. A. Russell, A. V. Overshiner and T. Lundburg.

The Dean Electric Co. of Elyria, Ohio, represented by W. W. Dean and A. E. Barker.

Frederick Greer, president, looked after the interests of Harvard Electric Company of Chicago.

W. H. Cram, A. J. Rousseau, J. F. Crook, Harry Durant, James Strasberg and G. L. Fisher represented the Automatic Electric Co. of Chicago.

A. L. Waterbury and C. M. Ripley of the American Conduit Company.

L. G. Le Bouveau represented the Ewing-Merkle Co. of St. Louis.

Carl Seyler represented Hubbard & Co. of Pittsburg.

W. H. Trimm and J. C. Hubacher represented the Monarch Telephone Mfg. Co. of Chicago.

J. S. Cuming, C. H. Wallace, J. A. Becker, J. P. Poertner represented the Central Telephone & Electric Co. of St. Louis.

F. G. Jones, James A. Kenny, W. W. McNeal of the American Electric Fuse Company of Chicago.

F. W. Pardee and F. R. Parker represented Frank B. Cook of Chicago.

W. P. Bowman and A. B. Conover represented John A. Roeblings' Sons Co. of Trenton, N. J.

E. P. Baird, Baird Mfg. Co. of Chicago.

W. E. Wetzel, Measured Service Co., Chicago.

Charles North, Frank Sapp, A. B. Kratz, North Electric Co., Cleveland.

W. A. Caldwell, J. B. Wiley, Standard Underground Cable Co., Pittsburg.

John C. Roff, Wesco Supply Co., St. Louis.

F. E. Donohue, American Electric Works, Providence, R. I.

H. D. Stroud, Controller Co. of America, St. Louis.

F. H. Medhurst, F. N. Reeves, Arthur Kneisel, Faller Automatic Telephone Co.

Ewing-Merkle Electric Co.: W. G. Brown, L. G. Le Bourveau, J. S. Arthur, W. J. Kennedy, A. B. Ewing, Jr., W. G. Simms, L. G. Kallock.

Wesco Supply Co.: J. W. Krueger, V. Eraggio, W. E. Eckloff, L. M. Zapp.

Kellogg Switchboard & Supply Co.: Franz G. Dommerque, secretary and general manager; F. V. L. Turner, J. C. Lewis, W. H. Hind, H. N. Farris.

Telephone Hygienic Company, represented by President Horace L. Cutter.

H. D. Kusel was in charge of the display of the Baird Manufacturing Co.; E. M. Deems, representing the Gordon Battery Co., of New York City; Frank B. Cook was on hand talking "Cook protectors"; G. H. Johnson represented the Western Telephone Manufacturing Co., of Chicago.

Among the delegates were: J. H. Bell, Salem, Ind.; A. A. Whitney, Mt. Gilead, Ohio; N. E. Watts, Staunton, Va.; Albert Schulter, Streator, Ill.; John F. Baldwin, Irontown, Mo.; C. A. Schock, Sherman, Texas; G. T. McQuillan, Lexington, Miss.; T. B. Lee, Pittsburg, Pa.; J. B. Earle, Waco, Texas; Edward Rotau, Waco, Texas; O. F. French, Cleveland, Ohio; H. T. Dalrymple, Mt. Gilead, Ohio; B. B. McMeal, Chicago; Wm. A.

Digitized by Google

Hopkins, Jr., Columbus, Ohio; P. J. Wenich, Monroe, Wis.; C. E. Nicholas, Columbus, Ohio; Dwight E. Zapp, Mt. Vernon, Ohio; C. Y. McVey, Cleveland, Ohio; L. F. Blasingam, Hawkinsville, Ga.; O. C. Snider, Kansas City, Mo.; Frank L. Beam, Columbus, Ohio; C. H. Judson, Council Bluffs, Ia.; L. W. Stanton, Cleveland, Ohio; C. W. Kleine, Trenton, N. J.; Maxime Reber, St. Louis, Mo.; E. Land, Grand Rapids, Mich.; C. J. Baer, Topeka, Kans.; Edward L. Barber and James E. Brailey, Wauseon, Ohio; Virgil Bunton, J. W. Sidener, John Wallas, and Ira J. Baker, of the Lebanon, Ind., Independent Telephone Co.; Lee Henry, New London, Ind.; C. E. Stinson, Home Telephone Co., Toledo, Ohio; Guy Walks, Newark, Ohio; James McClamrock, Frankfort, Ind.; N. W. Karrenbock and J. B. Greensfelder, of Clayton, Mo.; F. R. Parker, of Chicago, Ill.; N. E. Liggett, Marysville, Ohio; Paul Latzke, of New York City; M. R. Nyman, of Chicago; THE AMERICAN TELEPHONE JOURNAL; C. L. Brown, Aberdeen, Kansas; E. Fledderjohann, Logan, Ohio; J. C. Meyers, Degraff, Ohio; D. C. Yoder, Toledo, Ohio; P. E. Allison, Atlanta, Ga.; George N. Methany, Lima, Ohio; William Van Middlesworth, Racine, Wis.; Kempster B. Miller, Chicago, Ill.; F. M. Flesk, Piqua, Ohio.

MANUFACTURERS' EXHIBITS

None of the manufacturers had exhibits at the hotel. Those having exhibits in the Electricity Building, World's Fair, made special arrangements to receive delegates.

THE CENTRAL TELEPHONE & ELECTRIC COMPANY.

The booth of the Central Telephone & Electric Company in charge of President Cuming and C. H. Wallis, who extended their courtesy to the visiting delegates, has a very attractive exhibit of the various types of telephones and apparatus which the company manufactures, and which are displayed in such a manner as to attract the attention and commendation of all visitors.

THE CONTROLLER COMPANY OF AMERICA.

H. D. Stroud and Mr. Mahon represented the Controller Company of America at its booth in the Palace of Electricity. This company has a practical demonstration of its system in operation, and has also supplied the Kinloch Telephone Company of St. Louis with Stroud collectors, which are in use throughout the Fair grounds.

THE AUTOMATIC ELECTRIC COMPANY OF CHICAGO, ILL.

The Automatic Electric Company of Chicago has a most attractive display of its apparatus in its booth. It consists of a section of a 10,000 capacity board, 200 stations being installed. The exhibit is in charge of H. D. Critchfield, J. F. Crook, H. A. Rousseau, H. S. Durant, G. L. Fisher and James Strasburg.

FALLER AUTOMATIC TELEPHONE COMPANY OF NEW YORK.

The exhibit of the Faller Automatic Telephone Company was in charge of F. H. Medhurst, F. N. Reeves and Arthur Kneisel.

EWING-MERKLE ELECTRIC COMPANY OF ST. LOUIS.

At the booth of the Ewing-Merkle Electric Company of St. Louis, W. G. Brown, L. G. Le Bourveau, J. S. Arthur, W. J. Kennedy, A. B. Ewing, Jr., W. G. Simms and S. G. Kallock received visitors.

WESCO SUPPLY COMPANY OF ST. LOUIS.

At the exhibit of the Wesco Supply Company in Block B a very attractive display of apparatus is shown in charge of J. W. Krueger, V. Eraggio, W. E. Echoff, L. M. Zapp.

KELLOGG SWITCHBOARD AND SUPPLY COMPANY OF CHICAGO, ILL.

Franz J. Dommerque, secretary and general manager of the company, together with F. V. D. Turner, J. C. Lewis, W. M. Hind and H. N. Farris, had charge of that company's exhibit.

THE AMERICAN ELECTRIC FUSE COMPANY.

The American Electric Fuse Company was represented by Frank B. Jones, James A. Kenny, W. W. McNeal. This exhibit was very attractive and drew much approbation from the delegates.

THE TELEPHONE HYGIENIC COMPANY.

The Telephone Hygienic Company was represented by the president, Horace L. Cutter, and has for display some ingenious hygienic attachments used in connection with telephone apparatus.

W. N. MATTHEWS & BRO. OF ST. LOUIS, MO.

W. N. Matthews & Brother had a very attractive display of Stombaugh Guy Anchors in Section 8 of the Electricity Building.

THE LECLANCHE BATTERY COMPANY OF NEW YORK.

The Leclanche Battery Company of New York exhibits its celebrated "Gonda" batteries, of which it has several different types.

WESTON ELECTRICAL INSTRUMENT COMPANY OF WAVERLY PARK, N. J.

The Weston Electrical Instrument Company has one of the most expensive booths in the Electricity Building. The display of the apparatus includes portable measuring instruments of all descriptions. C. P. Frey is in charge.

THE STANDARD UNDERGROUND CABLE COMPANY OF PITTSBURG, PA.

The Standard Underground Cable Company has a most attractive and unusual exhibit in conjunction with the McRoy Clay Works. This exhibit shows a section of underground conduit construction illustrating the methods of building, also pulling-in cable and the manhole construction.

NATIONAL CARBON COMPANY OF CLEVELAND, OHIO.

National Carbon Company of Cleveland exhibits a complete line of both dry and wet batteries, including the largest dry battery ever constructed. Various types of carbons, battery plates and other pieces of apparatus which are made of carbon are shown.

AMERICAN CONDUIT COMPANY OF CHICAGO, ILL.

The American Conduit Company has an exhibit of subway construction which illustrates its bituminized fiber conduit. This exhibit is in charge of C. M. Ripley, who is always ready and willing to give all the information desired about this type of underground construction.

BAIRD MANUFACTURING COMPANY OF CHICAGO, ILL.

The Baird Manufacturing Company has on view a complete line of pay-station apparatus, time stamps, call registers and peg counters. This exhibit is very attractive and illustrates very fully the extent of use to which the pay station has been brought.

ELECTRIC STORAGE BATTERY COMPANY OF PHILADELPHIA, PA.

The Electric Storage Battery Company exhibits a very complete line of chloride accumulators, together with a map which shows the location of its installations throughout the United States.

KESTER ELECTRIC MANUFACTURING COMPANY OF CHICAGO, ILL.

The Kester Electric Manufacturing Company has an unusual feature in connection with its exhibit in the shape of a clock made entirely of ordinary pins joined together by means of Kester self-fluxing solder. This clock is run by electricity and furnishes an illustration of ingenuity and painstaking care.

THE TELEGRAPH, TELEPHONE AND CABLE IN WAR

Paper Presented at the International Electrical Congress at St. Louis

By Samuel Reber, Major, General Staff, U. S. A.

"WAR," says Von Moltke, "is the only science that lays under tribute all the other sciences." The great discoveries and advances in science made during the past century have been utilized in the art of war, and none, with the possible exception of steam, has produced a greater change in the application of its principle than the use of electrical means of communication. The saving of time, and subsequently money, by the use of the telegraph, the telephone, and the cable in the affairs of daily life has been beyond calculation. The use of electrical means of communication is now absolutely necessary to success in war, not only in the grand strategical combinations of a campaign, but also in the varying tactical situations on the field of battle.

Copyrighted 1904 by Waldon Fawcett. *U. S. Automobile Telephone Station.*

The element of time is one of the dominating factors in modern warfare with the enormous expense incident to the equipment, maintenance, supply and movement of large fleets and armies. The longer the duration of a war, the greater the strain of the physical and financial resources of the nations involved. The ultimate result of a war may depend on the financial capacity of a nation to pay, feed and supply a victorious army. War disturbs not only the normal internal conditions of belligerent nations, unsettles and frequently paralyzes their trade, industrial and agricultural prosperity, but also produces a far-reaching result on the commerce of the world.

Nations are now so intimately connected by business and fiscal ties that the effects of a war are quickly felt in the markets of the world. Although business may be stimulated for a while by a war, the ultimate effect must be one of depression. The exhaustion of the resources of one of the family of nations, caused by a protracted war, is felt to a greater or less degree by all the others. Anything which tends to shorten the duration and limit the sphere of a war is a decided gain, not only to the belligerents involved, but to the world at large. Electricity with its space and time annihilating properties has proved an ideal agent in shortening the duration of wars.

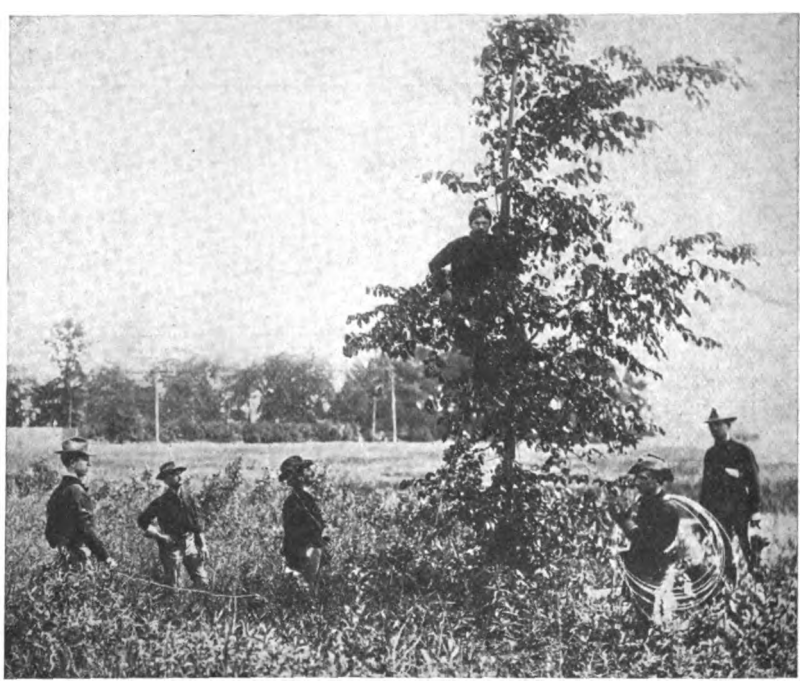
Napoleon in one of his maxims of war has said: "Le secret de la guerre est dans le secret des communications." It is absolutely necessary for the commander of an army to have rapid and positive means of communication for the transmission of orders, instructions and information from his extreme outposts in contact with the enemy back to his base in the rear of his army, and with all independent commands engaged in the theatre of operations.

The development of the use of the telegraph, telephone and cable in war has been along lines similar to those of commercial practice. The engineering principles are the same, but the operative conditions are, of necessity, more exacting and difficult. Efficiency and certainty of operation under all conditions are the fundamental principles governing design. Cost of installation and economy of operation are of less importance than absolute continuity of service. It is not to be understood, however, that due regard should not be paid to cost of installation and main-

Digitized by Google

tenance, but commercial methods fail under the stress of war conditions. A large number of ingenious methods and apparatus have failed on account of delicacy of operation or complication of design. Any apparatus that can not stand lack of attention and skilled supervision, exposure to weather, rough handling in transportation, and the effect of the blast of heavy guns, can not be relied on at the critical moment of its use in actual battle. Portability, simplicity and mechanical strength are essential requisites of all apparatus used in the service of field communication. The demands of a fortress system of communication are not as exacting, while the installation and operation of military cables follows the commercial practice of the nations using them.

It is impossible in the scope of a single article to give the characteristic features of the systems and apparatus employed by the various nations for military purposes, or the organizations of their special technical troops. With the exception of the United States, all the great military powers of the world control the service of electrical communication in time of peace as part of their civil establishment. Experience has proved that in time of war and especially in the field of active operations, this service must be part of the military establishment. All the great nations have special technically trained troops to operate their military systems. The operation of a system by joint civil and military control has proved a failure in the past, and the experiment will probably never be repeated.



Constructing a Line Through Difficult Country.

The service of communication is, in general, separated into field and fortress work. The fortress system consists of the permanent lines, usually underground, connecting the various works in the line of circumvallation around fortified positions, and in seacoast works, the system of fire control and direction for the laying and training of the haevy batteries, rapid-fire guns protecting the mine fields, and the searchlights. The details of such systems are zealously preserved as governmental secrets for obvious military reasons. For armies operating in the field a complete chain of communication should exist from the outposts in touch with the enemy back to the capital of the nation, or the main base of operations, which is connected to the seat of government by permanent lines. In case of over-sea operations the base is connected by cable.

Depending on the construction used, the chain of communication is usually divided into three parts, permanent, semi-permanent, and temporary, or flying lines. Permanent lines are usually those existing in the country or are built after the army has advanced. They are ordinarily outside of the zone of active operations, their construction following the usual engineering methods. When taken possession of and operated by the army the methods used are those of established commercial practice. Semi-permanent lines are used to connect the principal bases or depots of supplies on the edge of the zone of operations with the field bases within it, and the general headquarters. Field or flying lines are used in the zone of active operations and connect the general headquarters with all the principal subdivisions, even to the extreme outposts. In this service expedients of rapid construction of every nature are employed, and the telephone is fully utilized. It is possible to construct a line, using lances of ash or bamboo to support the wire, at the rate of from one to three miles an hour, depending on the character of the ground. By the use of light field cable and bare wire a detached cavalry column, or even a reconnoitering party, can be connected during its movement with the main body. At night each brigade and division headquarters can be connected by a field telephone system with the corps headquarters and the supply points, while the extreme outposts can instantly report any movements on the front. On the field of battle the commanding general can be connected telephonically with his corps commanders, and they in turn with their division and brigade commanders.

Major Von Etzel, of the Prussian army, first suggested in 1839 to the War Department the possibility of employing the electrical telegraph, but it was not until 1844 that a board of officers was convened to consider this subject, and not for several years subsequent to that date was the necessary material obtained and a line built. There is no record of the result of this experiment. In 1853, during the manœuvres of the Austrian army at Olmutz, a movable telegraph line was constructed by stationing men at intervals to hold light lances to support the wire. Naturally the result wa snot considered successful.

The first practical application of the telegraph was during the siege of Sevastopol by the allied armies in 1855, where the searchlight was also first tried, the current for the arc being supplied by primary batteries. The dynamo was not used in searchlight work until the siege of Paris in 1871, where it was employed by the Germans, the French using primary batteries for the arc. During the siege of Sevastopol the lines were of permanent character and were not used for tactical purposes.

The development of the military telegraph system of the English army appears to have progressed quite slowly at first, as its importance does not seem to have been recognized by the authorities. When the Ashantee war of 1873 broke out no field telegraph material existed in the army, and none reached the troops in the field until they were well into the interior. When the supplies were received they were both insufficient and unsuitable, but assisted in hastening the termination of the war. Again in the Zulu war in 1879 no provision seems to have been made at the beginning of the campaign. Better use of the telegraph was made in the Afghan campaign of that same year in the face of great difficulties of operation caused by the constant cutting of the lines of the enemy. In 1881 Major Cardew introduced the telephone as a receiver for telegraph purposes, using a buzzing note produced by an interrupted current for transmitting Morse characters. This system has been modified and extensively used with great success in our own service.

The buzzer, as it is called, is simply a coil of low resistance and high self-induction in circuit with a telegraph key, an interrupter and a few cells of dry battery. On opening the circuit

Digitized by Google

the discharge from the coil goes to the line, and owing to the high self-induction and consequent comparatively high e. m. f. enough current reaches the other end of the line to give audible signals. By the use of the buzzer leaky and broken lines which would be absolutely grounded for ordinary Morse working can be operated. Major Cardew's system was first used in the Egyptian campaign of 1882. The telegram announcing the result of Tel-el-Kebir was sent from the battlefield by this system.

Profiting by their previous experiences, about which an English writer of high authority in 1894 naively said, "Some ill-luck seems to have attended our telegraph arrangements on service," the British had a completely equipped and supplied telegraph organization in the field during the recent Boer war in South Africa. Some 220 separate field cable-lines of 3,749 miles in lenth, and 2,191 miles of aerial line were constructed by them, the traffic on some of their main trunks being so heavy that they used Wheatstone automatic instruments. The telephone was also extensively used. The defense of Ladysmith was conducted entirely by telephone, and it was said that the telephone system saved the place when the Boers attacked Wagon Hill and Caesar's Camp on January 6, 1900. To protect their long line of communication against the raids of the Boers, blockhouses were built at intervals of about one thousand yards and every second or third one supplied with a telephone connected with centers for the dissemination of information and for the obtaining of succor. Certain of the blockhouses were supplied with telegraph instruments in addition to the telephone. "The blockhouses together with the systematic 'drives' organized by the Commander-in-Chief finished the war, as the Boers themselves confess."

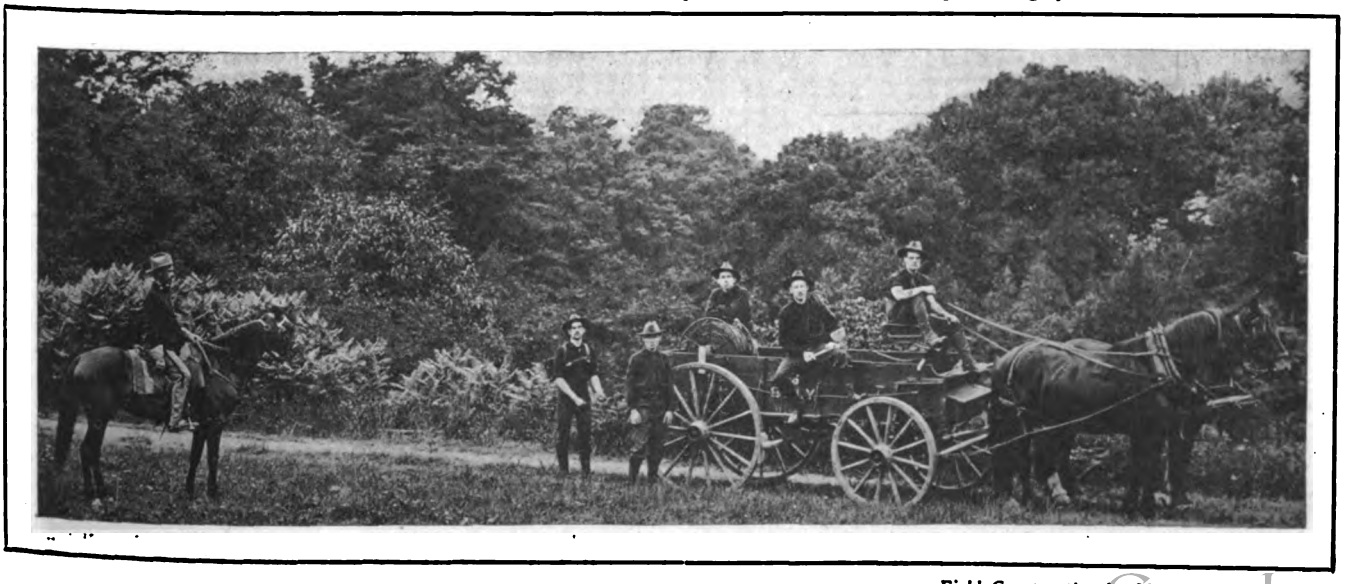
In the Spanish-American war, though of short duration, the telegraph, telephone and cable played a most important part, both strategically and tactically. In the operations in front of Santiago the telephone was used to connect the trenches along the thirteen miles of front. The bombardment of Santiago was directed by telephoning from the front to the shore where range and direction were flagged to the fleet. The operations are summed up in the following extract from the official report of the Chief Signal Officer for 1898:

> The major-general commanding the Fifth Army Corps reached by telephone points on the right, center, and left of his line within 400 yards of the enemy, and left of his line within 400 yards of the enemy, and communication with his subordinate commanders was not only possible at all times, but was continuously maintained, as there lines worked twenty-four hours in the day. On the other hand, the major-general commanding the Fifth Corps was able to communicate directly with the admiral commanding the fleet through the telephonic station near Aguadores. In addition, the War Department, with all its bureaus and the supply depots of a great nation, were within twenty minutes of the general commanding, so that any deficiencies of equipment could be asked for or reinforcements requested; and further, he was able to keep in touch with the President, the Secretary of War, and the Commanding General of the Army, so as to receive at critical moments such advice, encouragement, or assistance as might advance the interests of the campaign.

In the Porto Rican campaign every part of the widely distributed invading army was connected by telegraph and telephone from the first day of landing at Guanica to the termination of the war. The telegraphic and telephonic service was such that within 33 minutes after the receipt of the cablegram announcing the armistice which suspended hostilities the commanders of three separate divisions of the army operating in different parts of the island miles apart were ordered to suspend operations. In the case of two of the commands the message arrived just in time to prevent actual contact as the troops were in position for action, and at Guayama the lanyards stretched on the guns to open the artillery duel. In the Philippine campaign and the subsequent insurrection the telegraph and telephone were of great value, so much so, that the Commanding General remarked in 1901, "It is not too much to say that in the absence of this efficient service it would be impossible to hold this archipelago with less than 150,000 men, which is now well and efficiently held by 60,000." During the insurrection some 4,851 miles of aerial line were constructed and 500 miles of submarine cable laid.

In the present war between Russia and Japan it can be inferred from the meager published reports of the operations that both sides are using electrical means of communication to their full extent. It is known that the Japanese armies are connected together by a system of field lines, their outposts by telephone and their bases with Chemulpo and Japan by cable. On the day before the battle of the Yalu the fire of the Japanese howitzer batteries was controlled and directed by telephone, and on the day of the battle during the movement of the 12th Division its commander was continuously connected by telephone with the Commanding General of the Japanese forces. The value of wireless telegraphy to the Japanese navy in its operations in the China seas, and to the Russians by allowing the commander of a beleaguered place to communicate with his home government is too obvious for comment. It seems at the present state of the art that wireless telegraphy will not play as important a part in land communications as the telegraph or telephone until the present methods of its operations have been greatly improved upon.

The part played by the cable in the history of recent years has completely proved that its role is scarcely inferior to the military and naval forces themselves. All the colonial powers of the world have so arranged their means of cable communications that the cables are under their immediate control and touch only the shores of their own possessions or those of countries that are allied to them by treaty and community of interest. The control of the seas, one of the material elements contributing to the power and prosperity of a nation, is influenced largely by cable communications, and in a war in the future between two naval powers the result will depend largely on coal and cables.



Field Construction by Means of Wagon.

TELEPHONY AT THE ELECTRICAL CONGRESS.

ONE of the most valuable features of a great exposition is the opportunity "to talk things over." Visitors from all parts of the world are attracted by the exhibits, and on a common meeting ground the interchange of views and experiences of those whose tastes and avocations are similar is natural and inevitable.

In one respect the Electrical Congress held in St. Louis last week was unique—that is, in the attention given to subjects telephonic. This is partly due to the enormous extension which this means of intercommunication has received during the past decade, but, we believe, that the broad and open policy so generally advocated by Independent telephonists has been even a more potent factor, and now results in breaking down the short-sighted policy of secrecy with which the Bell interests have for so long endeavored to surround the telephone. The business of telephony is too complicated to be comprehended by any man, or even any set of men. It is so kaleidoscopic in nature that it must be viewed from every side of human life.

The telephone was one of the first of the discoveries which has produced the great electrical era of the past twenty-five years, but it has been outstripped both by the electric light and the electric railway. And why? Owing, we believe, very largely to this same policy of secrecy. Our friends of the electric light and the street railway long ago perceived that a free and frank interchange of experience and opinion was the surest way in the long run to develop business upon a broad and sound basis. For any one discovering something particularly new and useful there was the patent office standing ready to afford ample protection, and if the matter was not worth patenting it certainly was not worth secrecy.

Before the congress there were read half a score or more of papers upon subjects purely telephonic, all of which will bear the most careful perusal, and will be of the greatest value to the manager and operator as representing, upon the topics presented, the views of the best telephonists of the world. Many of these papers deal with the most vital of telephonic problems that now occupy attention, and they are treated with the most refreshing frankness.

In our previous issue a number of the papers were reproduced, while the balance appear in the current number. Mr. Kempster B. Miller discusses the problem of "The Automatic *vs.* The Manual Exchange." With his usual clear-sighted analysis Mr. Miller states that the solution of this problem lies in the answer to three questions: 1st. *Can* an automatic switchboard perform the work of the manual? To this he answers "Yes."

2d. Is the service afforded by the automatic board satisfactory to the subscriber? This is also answered in the affirmative.

3d. Is the expense of the automatic both in initial installation and annual maintenance comparative with the similar costs of the manual? As regards installation costs, Mr. Miller states that the automatic is considerably more expensive, about one-third, while as to annual expense he frankly states that as yet there has been too little experience with the automatic upon which to base a reliable opinion.

"Telegraphy and Telephony in Japan" are treated by Mr. Saitaro Oi. This paper is to all intents and purposes a history of the developments of telephony in Japan, from which it is pleasing to note that during the last twelve years the number of telephone exchanges have increased from 2 to 46, and the number of subscribers from 359 to 36,700.

OPINION OF EXPERT TELEPHONE ENGINEERS.

Dr. Hammond V. Hayes places before the Congress a paper which is a report of the operation of "Loaded Telephone Lines in Practice." From the technical standpoint it would hardly be possible for Dr. Hayes to have selected a topic to arouse more interest, or which would have been listened to with more profound attention by engineering telephonists. The problem of long-distance transmission is undoubtedly the technical telephonic problem of the future.

"The Telephone Problem in Large Cities" is the title of Mr. Dommerque's paper, in which the author rehashes the old question previously thrashed out on many a telephone battlefield, of the proper number of offices, or, rather, of the proper size of office which should be installed.

Prof. J. C. Kelsey, in a paper upon the "Dunbar Two-strand Common Battery System," compares the common battery switchboard circuits which have been adopted by the Bell and the Kellogg companies. The paper is a minute comparison of the two systems and chiefly interesting to the switchboard expert.

"The Theory of Telephone Exchange Development" is discussed by G. de La Touanne. The author enumerates the various items of expense which make up the cost of installation and the cost of operation, and then collects into a formula the various components and shows the method whereby telephone rates may be calculated to provide for operating costs and dividends.

A short paper by Joseph Hollos describes the systems for "Simultaneous Telephony and Telegraphy" which have been adopted by the Hungarian telephone department.

In Australia it has been found that aerial lead cables were exposed to considerable danger from the attacks of certain predatory insects. Mr. John Hesketh, under the title of "New Danger to Lead-Covered Cables," describes the ravages which these pests have wrought, and indicates some methods of protection.

In a paper entitled "High Frequency Telephone Tests," Dr. Kennelly describes some new methods of measuring telephone lines which will be of marked interest to both the student of mathematical telephony, from the theoretical aspect, and to the cable man, as outlining a method whereby tests on the wire plant, confined hitherto by reason of complexity to the laboratory, can now be made in the field. Dr. Kennelly's plan involves the use of the barretter, an invention of Fessenden, which consists of an exceedingly fine bit of platinum wire sealed in a glass tube. If the barretter be placed in series with a galvanometer and battery a steady current will flow, producing a constant deflection. Now if another source of electricity be connected to the barretter a new current will flow through it. This new current will heat the fine platinum wire, change its resistance, and so alter the former deflection of the galvanometer. Dr. Kennelly shows how this extremely sensitive instrument can be made available and valuable in the inspection of cables and switchboards.

Ofttimes the practical man turns up his nose at the scientist, and thinks, frequently with reason, that in its proceedings a congress is merely "talking through its hat." In this instance such is far from being the case. All of the papers deal with live telephone topics, and treat them from the business aspect. Even an hyperbolic cosine is robbed of its terrors by Dr. Kennelly's skill, and the barretter shown to be a simple, easily managed instrument, capable of great service to the wire chief and cable man. In all respects THE AMERICAN TELEPHONE JOURNAL aims to be practical, and the congress papers are reproduced in full because we believe that no practical man can afford to be without them.

HIGH-FREQUENCY TELEPHONE CIRCUIT TESTS

Paper Presented at the International Electrical Congress at St. Louis

By Dr. A. E. Kennelly, *Harvard University.*

In land-line telegraphy, it has for many years been a custom to test the circuits periodically by applying a steady assigned voltage to their sending ends, and measuring the strengths of current received to ground at their distant ends, through a milliammeter or equivalent apparatus.[1] Fig. 1 shows this well-known arrangement. An e.m.f. E volts is applied to the end A of a line L miles or kilometers in length, and the current-strength i is observed at B, passing to ground through the instrument of resistance R ohms.

It is known that for a uniform line of conductor-resistance r

$$i_r = \frac{E}{R_0 \sinh(La) + R_r \cosh(La)} = \frac{E}{R_1} \text{ amperes} \quad \ldots\ldots (1)$$

where[2]

$$R_0 = \sqrt{\frac{r}{g}} \quad \ldots\ldots \text{ohms} \quad (2)$$

$$\text{and } a = \sqrt{rg} \quad \ldots\ldots \text{per mile or kilometre} \quad (3)$$

ohms per mile or kilometer, and of leakage conductance g ohms.

The resistance R_r, represented by the denominator of the fraction in formula (1), may be called the "receiving-end-resistance" of the circuit; because it is the resistance which the circuit apparently offers to the applied e.m.f., E, as judged by an observer at the receiving end. If the maximum available e.m.f. at the sending end is, say, 200 volts, and the minimum received current-strength at the receiving end of the line which will operate the signalling relay is, say, 1 milliampere; then the "receiving-end-resistance"

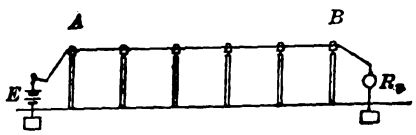

Fig. 1.—Telegraph circuit test.

of the line must not exceed 200,000 ohms in order that the received current in the steady state may suffice to produce a signal. During the variable states of rapid signalling, the effective "receiving-end-resistance" of the circuit may differ appreciably from that of the steady state. Nevertheless, the steady receiving-end-resistance furnishes a useful and reliable criterion as to the workable condition of the circuit. When the steady receiving-end-resistance of any such circuit exceeds some particular limit, the circuit becomes unworkable and requires the lineman's attention.

As an example of formula (1) the case may be considered of a uniform telegraph line, 345 kilometers long, having a conductor resistance of 15 ohms per kilometer, and an insulation leakance of 1 microohm per kilometer (corresponding to an insulation resistance of 1 megohm-kilometer). An e.m.f. of 80 volts is applied at A. What current-strength will flow to ground B: (a) when grounded directly, (b) when grounded through a measuring instrument of 32 ohms resistance? Here $L = 340$; $r = 15$; $g = 10^{-6}$; $E = 80$. $R_r = 0$ in (a) and 32 in (b).

By (2) $R_0 = \sqrt{\frac{15}{10^{-6}}} = 3873$ ohms, the sending-end-resistance for an indefinitely long line.

By (3) $a = \sqrt{15 \times 10^{-6}} = 0.003873$

$La = 340 \times 0.003873 = 1.317$; $\sinh La = 1.7321$; $\cosh La = 2.007$.

$\therefore$ by (1) $i_r = \frac{80}{3873 \times 1.7321} = \frac{80}{6708} = 0.01193$...amperes in (a)

and $i_r = \frac{80}{3873 \times 1.7321 + 32 \times 2.007} = \frac{80}{6772} = 0.0118$ amperes (b)

The receiving-end-resistance of the line would be 6708 ohms in case (a) and 6772 ohms in case (b).

In the case of a telephone circuit, precisely similar formulæ apply.[3] The conditions are, however, rendered more complex, because instead of a steady current system (frequency = zero) we have a multi-frequency alternating-current system. Each frequency of alternating current obeys the formula:

$$i_r = \frac{E}{Z_0 \sinh(La) + Z_r \cosh(La)} = \frac{E}{Z_1} \text{ amperes} \quad (4)$$

where

$$Z_0 = \sqrt{\frac{r + j l\omega}{g + j c\omega}} \text{ ohms,} \quad \text{the sending-end-impedance} \quad (5)$$

$$a = \sqrt{(r + j l\omega)(g + j c\omega)} \quad \ldots\ldots \quad (6)$$

n = frequency — cycles per second.

ω = angular-velocity = $2\pi n$ radians per second.

r = conductor-resistance — ohms per loop mile or kilometer.

l = conductor-inductance — henrys per loop mile or kilometer.

g = dielectric-conductance — mhos per loop mile or kilometer.

c = dielectric-capacity — farads per loop mile or kilometer.

$j = \sqrt{-1}$

E = effective harmonic e.m.f. at A or maximum $/\sqrt{2}$ volts.

i_r = effective harmonic current at B or maximum $/\sqrt{2}$ amperes $\angle$

Z_1 = receiving-end-impedance or maximum ohms $\angle$

Z_r = impedance of receiving apparatus or maximum ohms $\angle$

In order, therefore, to test a telephone circuit for effectiveness, it is only necessary to apply a known effective sinusoidal e.m.f. at A, and to measure the corresponding current strength received at B. The ratio of these quantities will be the "receiving-end-impedance" of the circuit at that frequency. If this impedance exceeds a certain value, assignable for each particular circuit, the circuit will be defective or even inoperative, and will require to be overhauled. It is, moreover, highly probable that the limiting length of circuit over which telephony is commercially possible is that which has a certain definite receiving-end-impedance at a certain standard sinusoidal frequency, whether the circuit is overhead, or underground, mixed, loaded, or natural, and after variations in sending-end-impedance have been taken into account.

It is not, of course, necessary that the measurements shall be made with a simple harmonic, or sinusoidal e.m.f. A mixed frequency or complex harmonic e.m.f. may be used. In that case, however, although the results will be comparable with each other, and with a certain empirical standard, they will cease to be interpretable or checkable by formula (4).

The object of this paper is to describe certain apparatus constructed for the purpose of measuring the alternating-current strength, at telephonic frequencies, received at the distant end of a telephone circuit, with a definite e.m.f. impressed on the sending end. The apparatus, therefore, is one which enables the receiving-end-impedance of a circuit to be measured for a given frequency, or enables that routine test to be made for telephone circuits which has so long been well known for telegraph circuits.

The receiving instrument in such a test should either have negligible impedance, or an impedance of magnitude similar to that of an ordinary receiving apparatus. There is no difficulty in producing an electrodynamometer of sufficient sensibility to enable a telephonic current-strength to be measured under laboratory conditions, but such an apparatus has relatively large inductance, and at a frequency of 1000 ~, such inductance develops 6283 ohms reactance per henry, while formula (4) shows that this impedance is multiplied by the hyperbolic cosine of the attenuated-length

Digitized by Google

$L.r$ in producing its effective share in the receiving-end-impedance of the circuit.

The device selected for the purpose (with Prof. Fessenden's permission) was the "solid barretter" used in the Fessenden system of wireless telegraphy. This consists of a minute loop of very fine platinum wire or filament. Out of several sizes of platinum filament tried, the size which gave the best results has a diameter of about 1.7 microns ($1.7\ \mu = 0.0017$ mm$=0.000067''$) and a length of about 1.5 mm (0.06"). The resistance of this filament is about 40 ohms per millimeter, or 1,000 ohms per inch, at room temperatures. Such a filament has a cross-section of 2.27×10^{-9} sq. cms (3.5×10^{-7} sq .in.), and a volume of 3.4×10^{-9} cc. With the specific gravity of 17.5 for platinum, the mass of the filament would be 6×10^{-8} gramme, and with the specific heat of 0.0323 for platinum, one erg of heat, accumulated in such a filament, would suffice to raise its temperature 12.3 deg. C.

To produce a platinum filament of such dimensions, the Fessenden device is seen in Fig. 2. A and B are two brass strips (25 mm $\times$ 6 mm. $\times$ 0.7 mm) pinned, side by side, to a hard-rubber supporting-block rr. Copper connecting wires c, c, are soldered one above. A short v-loop of silver wire b is soldered as a bridge at the lower ends. This silver wire has a diameter of about 0.075

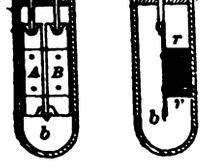

FIG. 2.— FRONT AND SIDE ELEVATION OF BARRETTER.

mm (3 mils), and has a central filament of platinum running through it, like the wick within a candle. The point of the silver v is dipped below the surface of strong nitric acid for a few minutes, and with the aid of a current of some milliamperes from a voltaic cell, the silver is rapidly dissolved away, leaving the platinum filament intact. The process is watched under a microscope, and stopped when the estimated right length of platinum filament has been exposed. The barretter is then protected from injury by being enclosed in a short glass test-tube containing air at the ordinary atmospheric pressure.

In adapting the Fessenden barretter to the telephonic circuit test, the arrangement of Fig. 3 was employed. Here the barretter b is made one arm of an *inductive* Wheatstone bridge. X, X, are two similar coils of low temperature-coefficient-resistance wire, wound upon closed magnetic circuits of steel wire, so as to have each 500 ohms resistance, and a relatively large reactance. A smaller reactance-coil x, of low resistance, of copper-wire winding, was included in the galvanometer branch. The galvanometer G is a wall-pattern d'Arsonval reflecting galvanometer of 620 ohms resistance, with a telescope and a scale at about half-meter distance from the mirror. No attempts were made to secure extraordinary sensitiveness, and 1 mm of deflection in the telescope represented approximately 10^{-8} ampere. The testing battery consisted of two storage cells (4.0 volts total e.m.f). The platinum filament in the barretter had a length of about 5 mm, a diameter of 3 μ, and a resistance of about 125 ohms at ordinary temperatures. Under these conditions a steady battery current of about 6 milliamperes passed through the barretter, raising its temperature some 25 deg. C. A balance at R, aided by a slide-wire r, was secured at about 135 ohms.

If feeble alternating currents are sent through the barretter, superposed upon the steadily testing current, they are practically confined to the arm b of the bridge by the reactances X, X, x, and heat the filament above the temperature due to the testing current. It is shown in Appendix I, that for *small* alternating currents, the change in the resistance of the barretter is proportional to the square of the strength of the superposed alternating current.

As shown in Fig. 3, the barretter b was connected at the receiving end of an artificial telephone cable lent by the American Telephone and Telegraph Company. This artificial cable has a conductor-resistance of 2820 ohms, and a capacity of 1.92 microfarads at 15 deg. C. Its CR time-constant was, therefore, 0.0054 second. The cable represents 32 loop-miles of standard underground cable of No. 19 B & S copper wire (88 ohms and 0.060 mfd. per loop-mile). The electrical length of this artificial cable could be adjusted to even miles. With the condenser c short-circuited, and a balance in R of 130 ohms, loud singing into the transmitter at A, operated by 1 storage cell, or 2 volts, produced a distant deflection on the galvanometer G, representing a received current-strength of nearly 100 microamperes, over the 32 miles of cable. This length represents the limit of "easy commercial" telephonic conversation. As the length of artificial cable in circuit was reduced, the strength of the received current increased, roughly as the inverse square of the length.

It was found practically impossible to obtain steady readings of the current-strength received through the barretter either over different lengths, or even over one and the same length, of the artificial cable, owing to variations in the transmitting apparatus, including the singer. The galvanometer showed that the intensity of the note delivered by the singer could not be steadily sustained for even a few seconds. Moreover, the difference in the effective current at the receiver due to variation in the distance between the lips and the transmitter was very remarkable. The current received, when the lips of the singer were only a few centimeters from the transmitter, was only a small fraction of that received

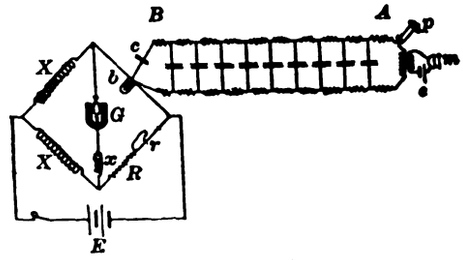

FIG. 3.— CONNECTIONS OF LABORATORY BARRETTER TESTS.

when the lips almost touched the transmitter cone. It was evident, therefore, that the conditions of sound-production at the transmitter would have to be standardized, if consistent and reproducible measurements were to be secured.

A short standard organ-pipe was lent for this purpose by Prof. W. C. Sabine of the Jefferson Physical Laboratory. This pipe sang a fairly pure note of $C''=512\sim$. It was connected by an electromagnetically controlled valve to a small air-holder, which, descending under a constant imposed weight, maintained a nearly constant amplitude of sound at the lips for half a minute at a time. By setting this pipe immediately facing the transmitter, and at a carefully maintained distance therefrom, fairly consistent measurements of alternating-current strength were obtained, with different lengths of cable in circuit. The results are indicated in the curve sheet of Fig. 4. It will be seen that the received-current strengths are roughly proportional to the inverse squares of the lengths of the cable, the inductance of which was negligible. The received current varied from 0.13 milliampere at 32 miles, to 1.16 milliamperes at 13 miles. The dotted line follows the values calculated from equation (4), taking $E=1.74$ volts. It will be seen that there is a rough agreement between the observed and computed current-strengths. The sources of the discrepancy between them were not, however, investigated.

It is evident that the sensibility of the test depends upon the smallness of the filament's diameter, so that it may become heated by a feebler alternating current, and also upon the minimum increase in resistance that can be accurately determined by the Wheatstone bridge. With 3-micron wire this was about 1/700 of 1 per cent. This represented the effect of a telephonic current strength of 23 microamperes. With 1.7-micro wire in air, the limit was reduced to about 7 microamperes, and with the same 1.7-micron wire *in vacuo*, to 3 or 4 microamperes.

Although such degrees of sensitiveness are attainable under

Digitized by Google

laboratory conditions, and might suffice for measuring telephonic conversation currents at the receiving end of long circuits, yet the reflecting galvanometer is quite unsuited for routine tests at the switchboard. Any galvanometer that can at present be used under switchboard conditions is much more limited in sensibility. If, however, the limit of resistance change to be detected is increased from 1/700 of 1 per cent. to 1/10 of 1 per cent., the minimum measurable telephonic current-strength becomes about 1/2 milliampere, with 1.7-micron wire in air. This current strength can be supplied over the longest commercial telephone circuits if an effective impressed alternating e.m.f. of about 25 volts be substituted, at the sending end, for the transmitter. That is to say, routine tests using switchboard instruments become quite practicable if a standard 25-volt alternator of telephonic frequency can be applied at the sending end of each circuit to be tested.

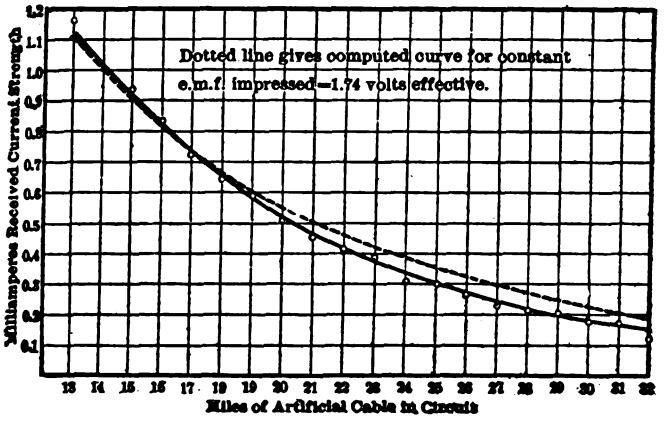

FIG. 4.—CURVE SHOWING RECEIVED CURRENT STRENGTHS AT EACH SUCCESSIVE MILE LENGTH OF ARTIFICIAL CABLE BETWEEN 13 AND 32 MILES.

In order to adapt the apparatus in this manner for switchboard use, a Weston milliammeter, in series with the barretter, was substituted for the reflecting galvanometer and Wheatstone bridge.

The connections of the switchboard apparatus are indicated in

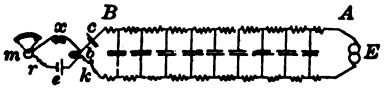

FIG. 5.—BARRETTER AND MILLIAMMETER AT RECEIVING END OF CIRCUIT OPERATED BY ALTERNATOR.

Fig. 5, where *b* is the barretter, with a 2-microfarad condenser in its circuit, to stop the testing current, supplied by the dry cell *e*, from flowing around the telephone circuit; *x* is a reactance coil to stop the telephone current from being diverted through the Weston milliammeter *m*, which gives a full-scale reading at 10 milliamperes over 100 divisions of 1/10 milliampere each. The dry cell *e* has an e.m.f. of 1.45 volts, and an internal resistance of less than 1 ohm. The resistance of the local circuit is adjusted, with the aid of the rheostat *r*, until the full deflection of 10 milliamperes is obtained. This requires 145 ohms in the circuit, of which about 120 are in the barretter, at working temperature, 8.5 in the reactance-coil *x*, 4 in the milliammeter and the remainder, or 12.5, in the dry-cell and rheostat, *r*.

Pressing the key *k* allows alternating current from the source *E* to pass through the barreter, thereby heating it, increasing its resistance, and temporarily reducing the current in the local circuit. Each division of the milliammeter scale represents 1 per cent. of the testing current, and 1/10 of a division or 0.1 per cent. can be readily estimated. A convenient strength of alternating current is one which will reduce the testing current 1 per cent., or one scale division. The action is very prompt and deadbeat, so that the needle's deviation follows at once upon the movement of the key. It is shown in Appendix II, that the strength of the received alternating current is equal to the square root of the needle's deviation in scale divisions, on pressing the key, multiplied by an instrument-constant, depending on the barretter. Thus in the actual instrument, one division of deviation from the full scale reading represents 1.4 milliamperes of superposed alternating current, with shunt multiplier of unity.

The source of standard alternating e.m.f. *E* employed with the switchboard testing-set was a small 12-pole inductor alternator, weighing about 2 kilogrammes, and originally designed for a very different purpose. When belt driven, this little machine could readily deliver a few milliamperes at a frequency of 1200 ~, and, when directly connected to a small motor, 600 ~, The rotor consisted of a laminated inductor cylinder with grooves and polar

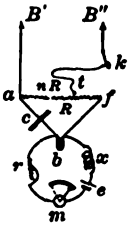

FIG 6.—CONNECTIONS OF BARRETTER HIGH-FREQUENCY MILLIAMMETER FOR TELEPHONE CIRCUITS.

projections. Owing to the peculiar magnetic actions set up during operation, the frequency delivered was very impure. Thus, when running at a speed corresponding to the principal frequency of 1200 ~, there was a prominent undertone frequency of 600 ~ in addition to overtones of 1800, 2400, and higher orders. Moreover, the pressure regulation of this little alternator was very defective, the voltage at terminals varying greatly with the nature and impedance of the circuit to which it was applied. Consequently, although this was the only convenient source of telephonic-frequency e.m.f. available, yet it left much room for improvement. An ideal source of alternating current for these tests

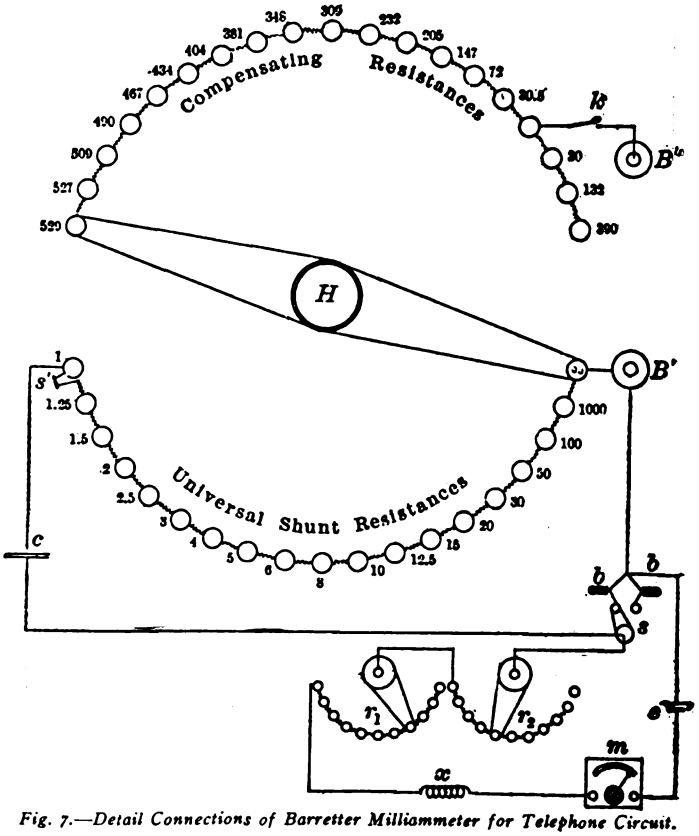

Fig. 7.—Detail Connections of Barretter Milliammeter for Telephone Circuit.

should be simple, reliable, consume little power, having constant freqency and terminal e.m.f. with a pure sine-wave.

Since the 1.7-micron wire melts at approximately 14 milliamperes in air at ordinary pressure (about 2.5 milliamperes *in vacuo*), and the steady testing current is 10 milliamperes, the barretter should fuse when the measured superposed alternating current reaches 10 milliamperes ($10 + j\,10 = 14.14$). Consequently, the barretter must be protected from alternating currents of more than 3 or 4 milliamperes. The theory of Appendix I also shows

Digitized by Google

that beyond 2 or 3 milliamperes of measured alternating current, the readings diminish in accuracy unless the formula of the measurement is complicated by the introduction of a correction. It becomes desirable, therefore, to protect the barretter by an adjustable shunt, as shown in Fig. 6. Here R is a resistance of 2000 ohms, permanently bridged across the barretter b and 2-microfarad condenser c. By shifting the contact t, to points distant nR ohms from a, where $n = 1, 1\text{-}2, 1\text{-}3, 1\text{-}4, 1\text{-}5$, etc., successively, the multiplying power of the shunt is made 1, 2, 3, 4, 5, etc., on the principle of the Ayrton universal shunt as shown in Appendix II, for all frequencies of alternating current.

The actual connections employed differ only from those of Fig. 6, by the insertion of compensating resistances in the wire kt, so as to keep the impedance of the apparatus constant under all conditions, and about equal to that of an ordinary telephone receiving apparatus at the testing frequency. In the case considered, the frequency selected was 600 ~, and the constant impedance, including barretter, condenser and universal shunt, 529 ohms. The full connections are given in Fig. 7.

B' B'' are the line terminals, connected to the telephone circuit under test, at its receiving end. H is a double-ended ratchet-switch, bridging diametrically across the two semicircular rows of contacts. The upper contacts are separated by the compensating resistances. The lower contacts belong to the universal shunt.

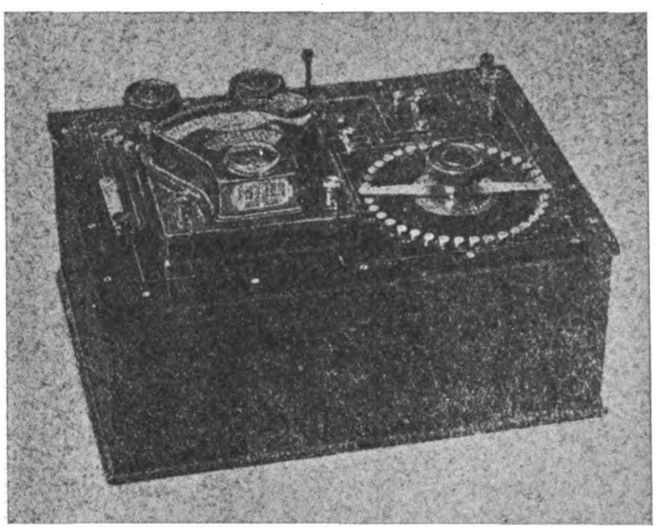

Fig. 8.

In the position shown, the barretter b and condenser c are entirely short-circuited, or shunted with a multiplying-power a; while the impedance of the apparatus, between line binding-posts, is 529 ohms, when the key k is depressed. On turning the handle H clockwise from this initial position, the multiplying power of the shunt is gradually reduced to 1, in 18 steps. By this means the instrument has a theoretical range of measurement from 0.5 milliampere to 4000 milliamperes.

Two barretters b b are installed, under the control of the switch s, one for working, and the other for reserve, in case of accidental fusing. The adjustable rheostats r_1 r_2 of 1/2-ohm and 5-ohm steps respectively, enable the testing current from the dry cell e to be kept constant at 10 milliamperes, except at such moments when the key k is depressed.

A view of the actual form of barretter receiving apparatus, as constructed by the International Instrument Company of Cambridge for the Engineering Department of the American Telephone and Telegraph Company, is seen in Fig. 8.

The process of testing a circuit with this apparatus consists in applying the required voltage and frequency of alternating e.m.f. at the sending end of the circuit, connecting the receiving ends to the line terminals B' B'', adjusting the steady testing current to the precise value of 10 milliamperes, pressing the testing key with the left hand, and turning the handle of the universal switch with the right hand from point to point by rachet, until a suitable small deviation of the needle is observed with the magnifying glass on the milliammeter scale. The square root of this deflection times the shunt multiplying-power, times the instrument constant, gives the effective alternating current in milliamperes received through the 529 ohms impedance in the instrument. From this current, and the applied effective e.m.f., the receiving-end impedance follows at once by Ohm's law. If the impressed e.m.f. is pure, or simply harmonic, this observed receiving-end impedance can be compared with its computed value, for the frequency employed. If the e.m.f. is a complex harmonic, the observed receiving-end impedance can be compared with that similarly observed

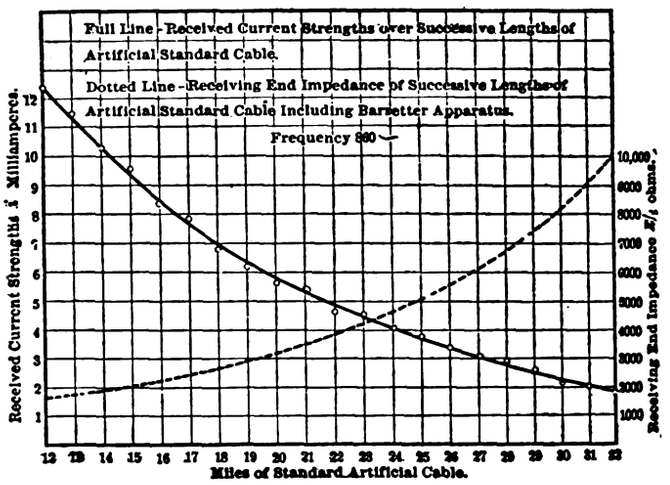

FIG. 9.

on varying lengths of artificial standard underground cable. The comparison will show whether the circuit under test is in satisfactory telephonic condition.

The curves of Fig. 9 show the current-strengths received with the apparatus of Fig. 8 through successive lengths of the artificial standard underground cable above described, and also the corresponding receiving-end-impedance. In this case the e.m.f. E had a magnitude of from 18 to 20 volts, varying with the length of the circuit, and the frequency was 860 ~ with components of 430 ~ and upper harmonics. It will be seen that the received current-strength increased from 1.85 milliamperes at 32 miles to 12.35 milliamperes at 12 miles, and the receiving-end-impedance from 1650 ohms at 12 miles to 10,000 ohms at 32 miles, with the particular frequencies used. With lower frequencies these impedances would ordinarily be less, and with higher frequencies greater.

The following table gives a few measurements made with the apparatus over various looped circuits, the inductor alternator and the barretter receiving apparatus being in the same room, near the switchboard. The frequency was 600 ~ (with 300 ~ and harmonics):

Length of circuit loop. Miles.	Wires. Gauge.	Applied e. m. f. E. volts.	Received current. Deflection divs.	Shunt.	i. Milli. amp.	Receiving end impedance. ohms.

The experimental research described in this paper was undertaken with the assistance of Messrs. Moses King, Jr., and E. A. Stevens, Jr., senior students in the Department of Electrical Engineering at Harvard, in consultation with the Engineering Department of the American Telephone & Telegraph Company, as represented by Dr. Hammond V. Hayes, Mr. H. S. Warren, Dr. George A. Campbell and Mr. G. W. Pickard.

We also desire to express our indebtedness to Prof. R. A. Fessenden, who assisted us with apparatus, barretter and valued suggestions, as well as to Prof. W. C. Sabine for apparatus and aid.

Appendices will appear in the next issue.

INDEPENDENT TELEPHONE ASSOCIATION OF PENNSYLVANIA

A CONFERENCE of representatives of the Independent telephone companies of Pennsylvania was held recently at the office of the United Telephone & Telegraph Company in Harrisburg.

There were present at this conference E. C. Wilson, of the Keystone Telephone Company of Philadelphia; J. G. Splane, of Pittsburg and Allegheny Telephone Company; George B. Rudy, of York Telephone Company; B. F. Meyers, of Cumberland Valley Telephone Company; F. E. Wunder, of Keystone State Telephone Company; W. D. Barnard, of United Telephone and Telegraph Company, and H. E. Bradley, of Eastern Traffic Assn.

The preliminaries of a proposed convention of representatives of Independent telephone interests were discussed, and it was concluded to hold the convention in that city on the 27th and 28th of this month, to conclude with a banquet at the Board of Trade on the evening of the 28th.

Papers will be read before the convention by experts on subjects of interest to those engaged in the telephone business as well as to the general public. A large attendance is anticipated and the meeting is expected to give great impetus to Independent telephone enterprises in this part of the country and to bring the various companies into closer relationship.

SIMULTANEOUS TELEGRAPHY AND TELEPHONY

Paper Presented at the International Electrical Congress at St. Louis

By Joseph Hollos.

THE question of simultaneous telegraphy and telephony is not of recent date. While, however, in some places, good results have been obtained in others the advantages reached by this combined using of telephonic circuits are hardly worth mentioning, and in view of the difficulties experienced in the service, it was thought preferable to abandon the scheme.

If we look closer at this question, we can at once observe that wherever the telegraph and telephone services are under the supervision of one and the same interested person, the results obtained are excellent. Where, however, the two systems are in different hands the result is unsatisfactory. Thus, in America, where the financial interest of the telephone companies is involved, because of the desire to increase income by leasing lines for simultaneous telegraphy, and where, for this reason, these two operations are under the control of one technical staff, the result is excellent. The results are also fair in the European services, if the same technical officer supervises both telegraphy and telephony, and one service is co-ordinated with the other. The result is, on the contrary, very poor in all cases if the telegraph and the telephone services are in different hands.

This is evident if we consider how greatly the one system interferes with the other; that is, that careless handling of the one interferes at once with the proper functioning of the other, the two systems thus being brought into mutual opposition.

For this reason the service must be arranged in such a manner that the two systems cannot interfere with each other, and in as far as troubles are unavoidable, they must be reduced to a minimum. If they should exceed certain arrangements must be provided to hold out the less important service without delay.

In this direction the Hungarian telegraph and telephone service can show good results by comparison with similar installations, and, therefore, it will not be without interest to outline the principles which were followed in the formation of the system.

Above all, the simultaneous installation must be the simplest possible, because only thus and with the fewest possible instruments may undisturbed working be obtained. For this reason the method of simultaneous working, founded on the Wheatstone bridge principle, was made the basis of procedure.

The telephone circuit is closed through two inductive branches. At their point of intersection the battery branch is led off to the group of telegraph apparatus, while the telephone apparatus is placed in the so-called galvanometer branch.

It is thus evident that the connecting-in of the telephone apparatus—namely the leading of the telephone circuit through the switchboard—requires some care, because if there is a ground in the switchboard connections, the telegraph working is disturbed. Even if one telephone circuit is directly connected to another, and there be simultaneous working on the latter, the two telegraph simultaneous systems are brought into contact, which again causes marked disturbance. This may also be caused by the operators ringing simultaneously on several circuits from the same common source of ringing current.

Even if only one of the circuits fed from the common ringing source is connected for simultaneous telegraphy, such working will still be slow, because, in ringing on the simultaneous conductor, we ring also on five or six other conductors. However well insulated these circuits may be individually the insulation of the simultaneous telegraph circuit will be so far reduced by the connection that it will hardly be possible to maintain continuous telegraph working.

It is true that we can remove all these difficulties at one stroke, by connecting the incoming telephone circuit, before leading it to the switchboard, to a repeating coil working then only on the other half of the repeating coil. But by this plan the difficulty is only transferred to the other side—the telephone side. Above all, we have a loss of energy in the repeating coil to which are added losses inevitably occuring in the signaling apparatus, and it may happen that with such an arrangement the telephone subscriber does not get as much as 50 per cent. of the incoming speaking energy into his receiver. We must strive, therefore, that along with the undisturbed working of the telegraph, the telephone working be kept at the same relative level that would exist in the absence of simultaneous working. Moreover, the repeating coil not only weakens the speaking current but also the calling current, and we must, therefore, take precautions in this direction.

Under these conditions it is inadvisable to connect the circuit first to the repeating coil. As long as the circuit is on the calling apparatus there is no danger of disturbing the simultaneous working. The disturbance arises only at the moment of connecting. For this reason it would be sufficient to place the repeating coil in the connecting cord; but in the same path there is also the clearing-out signal, and a great loss of energy might thus be incurred. This we may, however, remedy if the repeating coil is constructed in such a manner as to serve at the same time as the clearing-out signal.

The clearing-out signal is, as a rule, connected in the bridge between the two branches of the circuit, and its duty is by its great self-induction to prevent the wasting of any considerable part of the speaking current. How far it is able to satisfy this

Digitized by Google

demand might be readily ascertained by inserting a receiver in the shunt path. In spite of thus increasing the impedance of the bridge, we still obtain intelligible speaking even with a clearing-out signal of 2000 ohms resistance, if the latter is entirely embedded in iron. These currents do not so rigidly follow the rules which apply to strong currents and, therefore, inferences drawn from such rules do not apply in this case, as may be shown by a simple experiment. With such a clearing-out indicator 30 per cent. of the energy is lost on the average, and 70 per cent. only is available, as I have been able to ascertain myself.

With a well-constructed repeating coil, if arranged as a clearing-out signal, the loss is not greater. Consequently if we insert such a repeating coil into the connecting cord simultaneous working without affecting the telephone is secured.

The repeating coil transformed into a clearing-out drop naturally possesses a closed iron circuit. In European practice this plan is avoided and an open-circuit repeating coil is generally preferred. The question whether the repeating coil has an open or closed magnetic circuit does not affect the high frequency involved, and for weak currents this is of much less importane than the other losses that arise in an open-circuit repeating coil.

For relatively strong signaling currents the closed iron circuit is of decided advantage, because with open-circuit repeating coils it is not exceptionally possible to ring through with alternating current, while it is always certain when there is a closed iron circuit.

From the point of view of simultaneous working it only remains to separate the ringing currents.

This may be accomplished if alternations are used, by branching the ringing current at each operator's position on a separate repeating coil. Where batteries are used, which are to-day exceptional, each operator's position must be given its separate battery. This is a matter for the technical department.

As for the operating department it is only desirable that the telephone and telegraph operators should be able to communicate with each other quickly, so that they can co-operate in case of troubles.

In the simultaneous working apparatus itself, the branching coil is of the highest importance. It is most important that the inductance on the two sides should be equal. This is more important than the exact quality of their ohmic resistance. This, however, determines not only the resistance of the coil but also the size of copper wire to be used.

From the point of view of choking, it is desirable to use long coils; such coils, however, by reason of the phenomena of dispersion, prevent the complete neutralization of the telegraph currents, and, therefore, it is necessary to select short coils. With such an arrangement the operation of the telegraph apparatus is not perceptible on well-balanced telephone circuits.

In the Hungarian Telephone System the results hitherto obtained with simultaneous telegraphy and telephony, in the manner above described, have been excellent.

THEORY OF TELEPHONE-EXCHANGE DEVELOPMENT

Paper Presented at the International Electrical Congress at St. Louis

By G. De La Touanne.

THE question of telephone rates is one of widespread interest, but, although daily discussed, it is generally little understood by the public and sometimes even not by telephone managers. When looking at a large railway station and its extensive switching system, any one understands that every new track is a source of complication; but strange to say, as to the telephone, everything seems simple and cheap, because the subscriber's instrument is simple and easy to handle. It is just as if we considered the railroad industry easy, simple and cheap, because we have only to sit down in a car. The fault does not lie, perhaps, entirely with the public; the current opinion would possibly be less erroneous if the public were allowed more freely to learn what is behind the walls of a telephone office and what is the organization of the big telephone exchanges. Even the fact that to satisfy the call of one subscriber for any other of only 10,000 subscribers, involves provision for about 50,000,000 circuit combinations, does not make clear to the public the amount of capital, skill and inexhaustible care necessitated.

Thus, in spite of efforts to develop a better understanding of telephone affairs, it may not be useless to call to mind from time to time some of the conditions to which the telephone industry is subject. The following is an attempt to summarize the principal commercial questions met in starting a new telephone exchange. This attempt is necessarily academic, for I assume my city to be virgin ground, telephonically, and I leave competition out of account. These conditions are hardly to be found in practice, but it may not be without interest for others to compare with the theory here developed the data derived from experience, and I hope that some members of the section may be induced to make statistical contributions of actual results.

For illustration, let us consider a simple case, a single-office exchange to be started in a city of 50,000 inhabitants, one subscriber's instrument on each line. The income must cover expenses and provide a dividend. The outlay depends on the prospects of development. The first question is, therefore—What are these? It is exceedingly difficult to answer, even from what is known of old exchanges; the demand is quite different to-day from what it was in the early days. For want of precise data, we may reckon on 6 subscribers per 100 of population in, say 12 years, and perhaps 12 in 20 years; the 6 per cent. in 12 years seem very probable, and in 20 years the telephone will likely be more common than gas is to-day. Taking as the rate of increase of population in the city only the general rate of increase, 20 per cent. of the United States between the two censuses of 1890 and 1900, the present city of 50,000 inhabitants will have a population exceeding 60,000 in 12 years, and 72,000 in 20 years, that is, for the exchange 3,600 and nearly 8,500 subscribers, respectively. Therefore, we may plot the curve Fig. 1 of the mean yearly number n of subscribers supposed to be provided for.

The charges on the enterprise correspond first to the total capital invested; second, to the annual expense of working the exchange. Two portions are to be made of the total capital T, one, P, for permanent investment, another, F, as a portion of the floating capital necessary for the payment of the working expenses.

$$T = P + F.$$

Permanent Investment, P.

The part P is devoted to four classes of expenses, lines, land, building and apparatus (subscribers' instruments and central office apparatus), each presenting very distinct features.

Lines.

The line plant includes the wires and the distributing system of these wires.

As to the distribution of the circuits, there is no doubt that, the exchange being devised for several thousand subscribers, the

Digitized by Google

distribution will be almost entirely underground; nowhere, probably, shall we again see a new Stockholm telephone tower, however remarkable a piece of work it may be. Both the interest of the public in the street and the interest of the enterprise will forbid frequent underground construction or reconstruction. We want, therefore, sewers with cable racks or some form of conduit, but both of ample capacity. The former system is probably the ideal one, but much too costly for an exchange of the size considered, unless the sewer system exists and is available for the purpose, as in Paris. We turn, therefore, to conduits; and as a properly built conduit lasts for years, there is no risk, and our policy will be to plan at once a system of conduits substantial and flexible, and devised for the full number of subscribers contemplated, 8,500.

But for spare plant, it would be sufficient to have 43 ducts, one per cable, for as many 200-pair cables, divided at the office into three or four routes, then, further away, into routes of 10, 8 ducts and less for 100 and 50-pair cables. But spare plant is one of the most difficult things to foresee. In the conduits you are bound to have spare ducts, first, because you cannot determine the ultimate number of lines in every direction; you can only approximate; second, because spare ducts facilitate repairs; third, because the addition of a few ducts at the start costs very little, but becomes

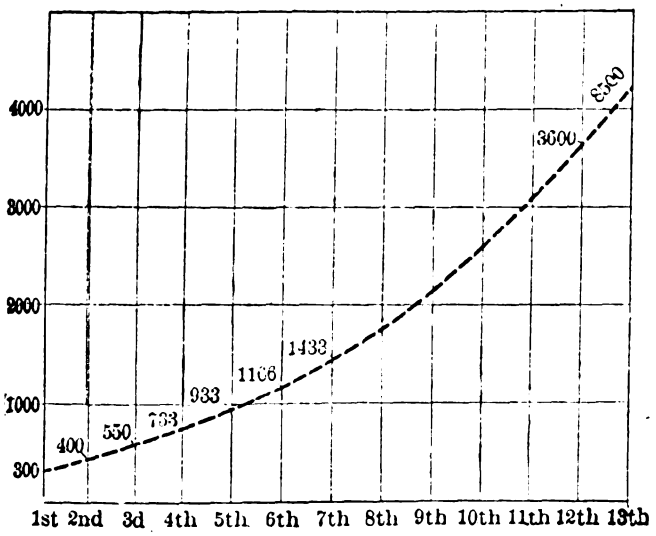

FIG. 1.—MEAN YEARLY NUMBER OF SUBSCRIBERS.

very expensive later on. The best practice allows an average of 40 per cent. spare ducts.

Outside the conduit system, the lines must be completed in different ways—inside house wiring, short sections of cable, pole lines, etc. An estimate of the probable average length l and of the probable average price p' per unit length (reserves included) will give the probable average lp' of this complement of the subscriber's line, while the principal part will be the cables drawn into the general system of conduits; the lines in the outlying districts are often disproportionately expensive; it is necessary to allow for this in estimating the average cost per subscriber.

As to lines in general ducts, the cost is that of the metallic circuit in the cable, laying and spares included. The lowest average preparation of spares is about 40 per cent.; this means that, in the calculations, the average length l' of underground circuit for a connected subscriber must be taken as 40 per cent. greater than it really is.

If there are rights of way to be paid for in any form—cash, free telephones, etc., this is a charge on capital, to the extent to which it involves immediate outlay; for a free telephone it will be the price of the user's instrument, line, jack, etc., and a proper proportion of land and building.

LAND, BUILDING, APPARATUS.

Apparatus comprises subscribers' instruments and central office equipment.

Calling the cost of a subscriber's set t, the total cost of the subscriber's instrument is nt.

Location and building must suit the type of switchboard adopted; storerooms, repair shops and offices can be leased almost anywhere; the switchboard with its accessories affords the only reason for buying land and erecting a building. The question of the switchboard must, therefore, be examined before the two others.

At the beginnings we shall use standard switchboards (cost b) for three reasons: First, they are cheap; second, untrained operators and inspectors cannot be charged with the handling of a multiple, with a complicated power plant and other accessories; third, up to, say, 600 answering jacks, there is little or no gain to the service in the multiple switchboard. But, of course, the land must be bought from quite other data and in view of the remote future, or what is considered a remote future in telephony, say 20 years; that is the space should provide a single floor for a multiple switchboard, to accommodate the ultimate number of subscribers, estimated at 8,500; if we put the average subscriber's connections per year ultimately at 3,000, or 10 per working-day, this will give 85,000 connections a day, which, with two-thirds of the traffic in five hours means a load of 11,333 connections per hour; at 200 per operator and per hour these 11,333 require 56.66 operators during the busy hours, let us say 57, able to reach the total number of jacks; this they will do with 19 sections, equipped with 450 answering jacks each; the 19 sections, with two end-sections, will have in a straight line (or in horseshoe shape) a length of about 129 feet. In dealing with the working capacity of the switchboard, we shall do better to abandon the old expression "subscribers per operator," and talk of "connections per operator's hour." "How many subscribers do the operators attend to?" is a question of idle curiosity, if not completed by another one as to the average number of connections per subscriber during the busy hours. "How many connections per operator and per hour, or more briefly, per operator hour, do you admit?" has a definite and practical meaning.

Coming back to the switchboard-room, we need a surface of about 3,700 sq. ft. to be doubled, if possible, for the cloakroom, the tearoom, etc. In round numbers the area of the land to buy will be 8,000 sq. ft. Such a purchase is almost free of risk, especially if not all built on, for the price L of the land is not likely to fall, and will probably rise: during the first years one floor will answer all the requirements of the service; if there is no existing building a light structure, one-story high, will suit all purposes, and the saving in building will partly make up for the price of the land, leaving the latter as good security for a loan, if necessary. The cost of this first construction, equipment included (protection against fire, heating apparatus, service telephones, furniture, lighting appliances, etc.), will be quite moderate. Some years later, when the enterprise is a success, a more substantial building (cost E) will be erected. Some may consider that the adoption of a single office is wrong, that it is better to have branch offices, and that, therefore, the above provisions for the head office are too costly.

The problem of sub-offices versus a single office is too important to be treated here, and we are leaving it out of consideration; we are studying simply the equipment of this single office. Taking the mean number of subscribers during the first year at 300, and for the second year at 400, we shall have four 100 line standards at once, another one the next year which will provide spare jacks for a time, and yet another one at the beginning of the third year. As the mean number of subscribers during this third year is assumed to be 550 (Fig. 1) we should have a margin of only about 100 at the beginning of the year, quite inadequate, unless, at the same time, we order a multiple switchboard to be furnished in about six months. As to this, to reduce the annoyance from frequent extensions in the switchroom when extensions are needed, we shall endeavor to make them for at least two years at a time. Even if it was not for the small size of the first multiple, we should, in consequence, order it for at least the mean number of subscribers in the fifth year, 933 from Fig. 1. In five years the traffic will be a known quantity, but to figure the probable cost B of the multiple switchboard, we must assume something; we can suppose that the average annual number of connections for these

Digitized by Google

933 first subscribers has reached its ultimate figure, say 3,000, which corresponds to a traffic of 9,330 connections per working day, two-thirds of which concentrated on five hours at 1,244 per hour is not full work for seven operators.

This shows, first, that it will be amply sufficient to get three sections with one end-section, three operators' positions for the section, 150 answering jacks per position; second, that seven operators, or even six, during the busy hours will easily handle the work, facilities being afforded for calling in two or three extra operators either to relieve the others or for learning the service during the busy hours; third, that the multiple must be provided with electrically worked signals (self-restoring drops or lamps), thus permitting three operators only being used most of the day, without being worried to replace signals in position; fourth, that, if proper precautions are taken at the beginning, the mounting of the multiple will be easy.

Working Capital, F.

Working capital is a necessity, and it must be liberally provided for. For some time, and before the earning power of the exchange has become substantial, the only source from which it can be derived is the capital invested: a part F of the total capital T will constitute the working capital.

As a résumé we have $T = P + F$ where

$P=p+$	$nlp'+$	$nl'p''$	$+nt+$	$\left\{\begin{matrix}b\\B\end{matrix}\right.+$	L	$+\left\{\begin{matrix}e\\E\end{matrix}\right.$
Permanent investment. Conduit.	Complements of subscribers' lines.	Subscribers' circuits in general conduits.	Subscribers' instruments.	Switchboard.	Land.	Building.

Annual Expenses, A.

These include:

Working Expenses	W
Maintenance	M
Depreciation	D
Sinking Fund	S
Contingencies	C
Reserves and Dividends	R

Working Expenses, W.

Under this head may be grouped:

Taxes.
Fire and Accident Insurance.
Rights of Way and Royalties.
Management.
Operating Force.
Labor.

As to taxes and insurance there is little to be said. Rights of way and royalties paid under one name or another include a certain proportion of annual expenses; for instance, on the free telephone hypothesis, the user's service (maintenance of instruments, lines and switchboards, operators' pay, etc.) is a charge which must be taken into account.

As to expenses of management, or generally speaking as to staff, for a few subscribers the staff may be proportionally very small; but when the system grows and becomes more complicated, it is otherwise; you want numerous statistics, accurate records for every part of the business, strictly kept accounts of the various kinds of expenses and earnings, a high grade of maintenance of the plant, that is, you want a numerous and skilled staff, without which you will lose money, and dissatisfy the subscribers by an inefficient service. Telephony is purely an industry of the age. The product to be delivered, a quick service with good commercial transmission is to be delivered in large quantity; it is a wholesale industry; like a big manufacturing or commercial house it can make money; or, it may fail completely, if the whole machine is not kept in perfect order and if every detail is not constantly watched. From actual needs, the proportion in big exchanges has gradually risen to one employee to every twelve subscribers; the manager must bear this in mind to prevent any further necessity of raising the rates; when fixing rates at the start he is bound to consider the inevitable expenses of the future and not the low ones of the present.

Maintenance, M.

Maintenance includes materials and salaries.

The money provided for salaries is part of the above working expenses and is not considered here.

The cost of materials M can be divided into: Materials for general conduits; cost p_1.

Materials for completing the subscribers' lines outside of the conduits; cost npl'_1.

Materials for the portion of circuits in the conduits; cost $nl'p''_1$.

Materials for the subscribers' instruments; cost nt_1.

Materials for switchboard and accessories; cost $\left\{\begin{matrix}B\\b_1\end{matrix}\right.$

Maintenance $\left\{\begin{matrix}e\\E_1\end{matrix}\right.$ for the building will be added, but done as it is for the most part on contract, there will be no distinction between materials and labor.

The conduit being of substantial construction will not cost much; maintenance may be put at 3 per cent. of the initial cost. As a more delicate piece of apparatus and submitted to hard work, the switchboard will cost more for maintenance, probably between 5 and 10 per cent.

$$M = p_1 + nlp'_1 + nl'p''_1 + nt_1 + \left\{\begin{matrix}b\\B_1\end{matrix}\right. + 0 + \left\{\begin{matrix}e_1\\E_1\end{matrix}\right.$$

Depreciation, D.

Depreciation differs widely for the different parts of the system.

For the reason just given, the conduit depreciation will be small and 5 per cent. is probably more than enough, but as we have no sufficient data as to the life of the modern conduits, we may retain this percentage.

The same percentage, 5 per cent., seems reasonable for cables in conduits.

The aerial subscribers' lines, which are of less durable construction, we put at 20 per cent., and the subscribers' instruments, which are often roughly handled, at 33 per cent.

The first building may have to be replaced in eight or ten years; we shall take 12.50 per cent. depreciation. The second building, being assumed to be of first-class construction, 5 per cent. seems proper.

Switchboards of the standard type are assumed not to be used after the end of the third year, because of the growth of the exchange; there will be probably an opportunity to use them again in the future; but we shall not rely upon this and shall, therefore, count 33 per cent. depreciation on the price of the six standards, in spite of the very short service of the sixth.

For the multiple switchboard, we could, on the basis of the manufacture of to-day, count 10 years' use; but it is hard to say that any system can be considered as fulfilling all requirements more than six or eight years, owing to rapid changes in type; we think to-day that we are pretty nearly perfect; the same has been supposed in the past and has always proved erroneous by the remarkable improvements of the switchboard. Therefore, if our aim is to give the best service obtainable (and that is the only way to make the telephone popular), we are bound to consider changing our switchboards even when in good working order; from the commercial point of view alone there may be strong reasons for the prompt adoption of a new and more efficient system; putting the maximum certain life of the switchboard at eight years corresponds to a depreciation of 12.50 per cent. If later improvements do not necessitate changing the switchboard, it will be used two years more, thus saving so much for other purposes.

$$D = 0.05p + 0.20nlp' + 0.05nl'p'' + 0.33nt + \left\{\begin{matrix}0.33b\\0.125B\end{matrix}\right. + \left\{\begin{matrix}0.125e\\0.125E\end{matrix}\right.$$

Digitized by Google

SINKING FUND AND INTEREST, S.

It will be perhaps difficult to avoid some borrowing; we shall assume that this is the case for a fraction mT of the total capital T and we have, therefore, to provide for a special sinking fund; we shall hasten, of course, the redemption of this debt as much as possible, in 10 years at the most; at 4 per cent. interest for 10 years, the annuity to be allowed is $0.1233mT$.

For the redemption of the capital $(1 - m)\ T$ we shall figure $0.05\ (1-m)\ T$ corresponding to redemption in 20 years.

$$S = 0.1233mT + 0.05(1 - m)T.$$

CONTINGENCIES, C.

Whatever expenses we may have provided for, there are always contingencies, gas explosions in manholes, flooding of the conduits, breaking down of fixtures or poles, accidents, etc. For such contingencies we shall add at least 10 per cent. to the above general expenses.

$$C = 0.10\ (M + D + W).$$

RESERVES AND DIVIDENDS, R.

The gross earnings must allow a certain sum to be put aside for further extensions or improvements. Considering the development of telephony, 10 per cent. of the total capital will not be too much to face the corresponding expenses.

Finally will come the dividends. Very little is to be expected in that respect for the first two or three years; later on a dividend of 7 per cent., when possible, will be only fair; but an increase of this dividend is not to be advocated even if the profits increase, until the reserves equal the capital, in one form or another.

As to annual charges, we allow 17 per cent. on the capital as a minimum to cover reserves and dividends, whenever circumstances permit, I mean when the rates calculated on that assumption remain within reasonable limits.

$$R = 0.17T \text{ (minimum)}.$$

INCOME.

The revenue is derived entirely from the rates paid by the subscribers (flat rate or measured service). The average sum to be paid per subscriber (or per conversation) is the quotient of the division of the annual charges A into the number of subscribers n' (or number of conversations, i. e., number of subscribers $\times$ average number of conversations). The number of subscribers n' to be now considered is lower than the number n used in the calculation of the expenses. We are not sure to get the subscribers for whom we have provided; and as the expenses are for the largest part not proportional to the number of actual subscribers, it would be unsafe to fix the rates from the numbers n. For instance, the three great elements of cost are the underground plant, land and building; it is obvious that you cannot wait until you have 8500 subscribers to be repaid for your outlay. The ideal would be to adopt what the well-known economist, Mr. Cheysson, has called the "Tarif avantageux." If you sell any desirable product for nothing, you will sell much of it and get no return; if you sell at a prohibitive price, you could have a profit if there was any selling, but as there is none, the return is again naught. Between these two extremes the curve of total return (number of pieces sold $\times$ profit per piece) reaches a maximum and the corresponding price is the most advantageous, the one giving the maximum profit. This we could determine if it were possible to get from the public true answers to a circular stating the different rates which could be accorded by the exchange on different numbers of subscribers and asking them to state the highest rate at which they agree to subscribe. For a time the exchange would stand by this "advantageous tariff"; later on, when the financial situation is stronger (loan repaid or reserves laid by for plant renewals), the rates will be reduced and a new "advantageous tariff" applied, benefiting both the enterprise and the public; if the subscribers knew that with a certain growth their own rates would be reduced, they would become soliciting agents. But this is impracticable, and the manager must base his rates on other considerations. He might plot the probable charges for a certain number of years and not only for the two or three first ones, and thus get a better idea of a scheme of rates to apply progressively and methodically, but only a knowledge of the local conditions will allow him to start on a proper basis.

Two general remarks may be added.

As has been noted above, conduit construction and land purchase are two heavy burdens on the enterprise. Therefore, if for some reason the cost of conduit is practically eliminated or considerably reduced, as by the use of a system of sewers or by the payment of a small rent for municipal or private subways, the telephone enterprise will be able to reduce rates very appreciably. Similarly a reduction will be possible if the concession is a long one and if only a small sinking fund rate is applied to the land, being justified by the nature of the property.

The next most important feature is the discipline, care and close co-operation of the whole staff. Since in many cases maintenance is a third or more of the gross earnings, it is needless to say that not only must the best construction be done at the start, but also that the greatest care is called for in the use of the plant and in its up-keep. As to the operating force, the necessity of discipline is still more striking. Discipline can increase the efficiency of this force as one to three or four. In this connection some may think 200 connections per operator hour too high, but in reality this should be taken as a minimum; it is a mere question of training. I remember in the Paris system of the old times with an average of two trunkings for each connection, a certain operator who could usually make 120 connections per hour; her work represented something like 400 connections an hour with a modern switchboard in a single office exchange. And about 1890, the operators at Nashville, Tenn., series multiple switchboard, with testing as distinct from connecting plugs, actually made 300 connections per hour and thought they could make 30 in five minutes (rate: 360 per hour) on a spurt. These same operators could doubtless handle 400 connections per hour with the improved switchboards of to-day (say one-fourth to one-third less, if the connections are trunked). This was due to discipline. The operators knew what they had to do and not to do, never talked with a subscriber, but connected him with the chief operator as soon as he began to say anything besides the number of the subscriber wanted, and so on. The force was well disciplined, so were the subscribers. The result was an efficient co-operation of both, giving the public the kind of service paid for.

If for any reason the management is afraid to give the operators more than say 1500 connections a day to handle, this has nothing to do with the operating capacity of the switchboard nor with the number of connections per operator hour; that means simply a special distribution of the force through the day, three gangs of operators, for instance, instead of two. The operator when at work must get all that can be got out of the switchboard, then go home; that is the place for rest, not the exchange. Let her work hard six hours or even five, and go; she will enjoy her rest and work more cheerfully. Hard work, good rest, is a sound rule everywhere.

THE WEEK'S MESSAGES

FINANCIAL.

BIRMINGHAM, ALA.—At a recent meeting of the stockholders of the People's Telephone Company, it was determined to cancel the present authorized issue of $100,000 bonds and to substitute therefor a new issue of $200,000 five per cent. twenty-year gold bonds. The new issue will be a first mortgage and will be secured by a trust deed on all of the company's property and franchises. The proceeds of the sale of the bonds will be devoted to settling outstanding indebtedness and to take care of the future growth.

CHICAGO, ILL.—The Interstate Telephone & Telegraph Company has given a trust deed to the American Trust & Savings Bank for the purpose of acquiring and enlarging the property of the Northwestern Telephone Company and retiring the bonds outstanding. Provision is made for the issue of $50,000,000 5 per cent. bonds.

WAVERLY, ILL.—The Waverly Telephone Company has increased its capital stock from $35,000 to $50,000.

CENTERMORELAND, IND.—The Centermoreland Telephone Company has increased its capital stock to $50,000.

EDINBURG, IND.—The Citizens' Telephone Company, of Edinburg, has increased its capital stock from $3,000 to $9,000. J. A. Thompson is president of the company.

SOUTH WHITELY, IND.—The Laimerr Mutual Telephone Company at a recent meeting decided to increase the capital stock from $25,000 to $100,000.

PHILADELPHIA, PA.—The report of the Keystone Telephone Company for the year ending Dec. 31st, 1903, shows total income of $482,832 and after paying operating expenses, etc., a net sum of $249,073.

AUSTIN, TEX.—The Citizens' Telephone Company has increased its capital stock from $4,000 to $8,000.

SANTA ANA, CAL.—G. A. Edgar, representing the United States Long Distance Telephone and Telegraph Company, was awarded the franchise for a telephone system here.

FRANCHISES.

ATHENS, GA.—The Georgia Telephone Supply Company, of Atlanta, has asked for a charter to install a local and long distance telephone system in this city. The company already has franchise granted for exchanges at Union Point and Madison.

CORDELE, GA.—The Farmers' and Business Men's Telephone Co. has been granted a franchise to do business here. J. C. Ledbetter is at the head of the company.

QUINCY, ILL.—The ordinance granting a franchise to the Quincy Automatic Telephone Company has passed second reading.

CITY OF MEXICO, MEXICO.—Jose Sitzenstatter, of the City of Mexico, has obtained from the Mexican government a concession for the installation of a new Independent telephone system in this city.

ARGENTINE, MO.—The Home Telephone Company has asked the city council for a franchise.

FREMONT, NEB.—The Fremont Telephone Company has been granted a franchise in this town.

MINDEN, NEB.—The Kearney Construction Company has been granted a franchise for an independent telephone system at Minden. T. F. Parmele, of Plattsmouth, is president, and W. J. Stadelman, of Kearney, vice-president. A first-class exchange will be installed in the near future.

GENEVA, OHIO.—A franchise has been asked by H. Hood, of Toledo, to operate a telephone system in this city.

COUDERSPORT, PA.—The Allegheny Valley Telephone Company has been granted a franchise. It will also ask for a franchise in Austin and Galeton. It is expected that the toll system will be in operation in the very near future.

ELECTIONS.

MONTICELLO, N. Y.—The Monticello Telephone Company has elected officers as follows: President, C. L. McLoughlin; secretary, G. L. Hatch; treasurer, H. F. Holmes.

NEW COMPANY NOTES.

ENTERPRISE, ALA.—The Enterprise Telephone Company has been incorporated with a capital stock of $5,000. The incorporators are: J. E. Henderson, Walden Thompson, T. D. L. Edwards, Nick Thompson. Local and long distance telephones are to be operated.

TALUCAH, ALA.—The Inter-County Telephone Co. has been chartered here by E. C. and C. B. Hageboom.

EUSTIS, FLA.—A new telephone company has been incorporated with a capital stock of $2,500 by the following incorporators: H. G. Whitsett, H. W. Bishop, Charles H. Newell, W. B. Merck and F. A. Hall.

FINDLAY, ILL.—The East Okaw Telephone Company has been incorporated with a capital stock of $600 by James E. Francisco, Archibald W. Lesley and Curtis Spicer.

FINDLAY, ILL.—The Mutual Telephone Company No. 3, of Findlay, has been organized. D. B. Yantis is president and G. H. Clay secretary. The line will be erected and telephones installed at once.

UNIONVILLE, IND.—The Unionville Telephone Company has been incorporated with a capital stock of $399. The directors are: George W. Welch, Milford Young, P. F. Lincicome, N. W. Lincicome and J. W. Slater.

LARRABEE, IA.—The Spring Cedar Mutual Telephone Company has been incorporated with a capital stock of $5,000 by Richard Gilbert and others.

VIELE IA.—The Viele Telephone Company has been incorporated with a capital stock of $3,000 by R. C. Conlee and others.

HILLSBORO, KY.—The Hillsboro and Flemingsburg Telephone Co. has been incorporated to do business here.

SCOTTSVILLE, KY.—The Scottsville and Barren River Telephone Co. has been incorporated by W. B. Ray, R. F. Hood and J. T. Hunt.

RED HOUSE, MD.—The Red House Telephone Company has been organized by H. Lisler and P. F. Snyder.

LITCHFIELD, MICH.—The Banker Telephone Company, of Litchfield, has filed articles of incorporation with the Secretary of State with a capital stock of $10,000.

STERLING, MICH.—The Aranno Telephone Company has been incorporated with a capital stock of $6,000.

MORRILL, MINN.—The Morrill Rural Telephone Company has filed articles of incorporation with a capital stock of $50,000. The directors are: Henry Foss, Fred Cassidy, Aaron Montz, Guy Cowill, John Thoen, C. S. Weigel and C. W. Bouck.

STILLWATER, MINN.—The Twin Lake Telephone Company has been organized and will build a line to connect with the city service. O. B. Masterson is president.

BOONEVILLE, MISS.—The Booneville Telephone Co., capitalized at $10,000, has been chartered, with Harvey Mayers, B. G. Henning and others as incorporators.

PURVIS, MISS.—The Purvis Light and Power Company has been organized here, with the following officers: W. H. Magee, president; J. W. Woodward, vice-president and general manager; C. V. Hathorne, secretary and treasurer. The purpose of the corporation is to operate an electric plant, local telephone system, water works and manufacture ice. Machinery has been ordered for the electric light plant.

LAMONTE, MO.—The Lamonte Telephone Company has been organized here with a capital stock of $6,600. The following officers were elected: W. E. Piles, president; F. Wimer, vice-president; J. A. Fleming, secretary, and John McCurdy, treasurer.

SPRING CREEK, MO.—The Spring Creek Telephone Company has been incorporated with a capital stock of $500.

WAYNE, NEB.—The Wayne Independent Telephone Company has been incorporated with a capital stock of $15,000.

JERSEY CITY, N. J.—The Dixon Home Telephone Company has bees incorporated with a capital stock of $125,000. The incorporators are: Charles N. King, W. Monds Green, Elmer H. Geran, all of Jersey City.

NORTH CREEK, N. Y.—The North Creek Telephone Company has been incorporated with a capital stock of $10,000. The incorporators are: C. A. Pereau, W. T. Campbell and J. L. Fuller.

ROMULUS, N. Y.—The McDougal Telephone Company has been organized here with the following officers: Addison Baldridge, president; R. C. Allen, vice-president; Clarence C. Updike, secretary, and Alexander Daldridge, treasurer. Work is to be begun at once and it is expected the new line will be in operation before winter.

VALOIS, N. Y.—The Caywood, Lodi and Valois Telephone Company has been incorporated with a capital stock of $5,000. Incorporators are: W. Traphagen, of Caywood, Charles Marsh and Bert Van Vleet, of Valois.

NORTHWOOD, N. D.—The Red River Valley Telephone Company was destroyed by fire with a loss of about $300.

CLARIDON TOWNSHIP, OHIO.—The Beach Telephone Co. has been incorporated by W. O. Miller, Levi Harruff, Joseph Klinefelter, E. F. Tittlebaugh and Philip Ruehrmund; capital, $10,000.

MARION, OHIO.—The Besch Telephone Company has been incorporated with a capital stock of $10,000 by the following incorporators: W. O. Miller, Joseph Klanefeller, E. F. Tittlebaugh, Levi Harruff and Philip Ruehrmund.

NORMAN, OKLA.—The Farmers' Central Telephone Co. has been chartered with a capital stock of $5,000. The incorporators are: G. E. Fuller and J. W. Abscher, of Franklin, and J. P. M. Ham, of Norman.

HERNDON, PA.—The Mahoney and Mahantongo Telephone Company has been organized here.

BATESBURG, S. C.—The Batesburg Telephone Co. has been chartered by William Westmoreland, J. T. Kneece and W. P. Timmerman.

ST. STEPHENS, S. C.—W. A. Floyd, W. P. Russell, R. Rittenberg and W. A. Bunch have incorporated the Kerkeley Telephone Co. They have forty miles of line in operation and contemplate various extensions to the system.

NASHVILLE, TENN.—The Tri-State Telephone Company, of Shelby County, has been incorporated with a capital stock of $10,000 by Charles D. M. Greer, J. T. Warren, F. N. Fisher, L. T. Cavanaugh and A. Outzen.

HUBBARD, TEX.—The Hubbard City Telephone Company has been incorporated with a capital stock of $5,000 by C. W. Hobson, A. L. Collins and Hyde Macfarlane.

NACOGDOCHES, TEX.—The Nacogdoches Southeastern Telephone Co. has been chartered. Purpose, the construction and operation of telephone lines in Nacogdoches County. Incorporators: Charles Hoya, June C. Harris, Allan Seale, Robert Lindsay and George H. Nusenheimer.

RELIANCE, TEX.—A telephone company has been organized at this place to build a line from Reliance to Bryan. The line will be four miles long. The promoters are: Howell Brothers, O. Saunders, Mr. Morgan and Walter Edge.

RELIEF, VA.—The Frederick & Shenandoah Telephone Company has been incorporated with a capital stock of $1,000. The officers of the new company are: President, I. Funkhouser; vice-president, I. A. Graves; secretary, E. R. McDonald; treasurer, H. A. Richards.

UNDERGROUND.

LITTLE ROCK, ARK.—A meeting of the electric street and ordinance committees will be held to take up the ordinance regarding underground telephone wires. The ordinance has already been drafted and will be submitted to the city council.

Digitized by Google

RIVERSIDE, CAL.—The Home Telephone Company has been granted permission to lay underground conduits in the business section of the city.

COMBINATIONS.

JACKSONVILLE, FLA.—The Jacksonville Telephone Company has been sold to D. L. Gerow.

ST. JOHNS, N. B.—The Union Telephone Co. and the Central Telephone Co., operating in New Brunswick, intend to amalgamate. The Union Co. has its headquarters at Florenceville, and uses the Stranger automatic central. The Central Co. operates from Bellisle.

TORONTO, ONTARIO, CANADA.—The Toronto Municipal Association passed a resolution favoring the purchase by the government of the trunk telephone lines.

MISCELLANEOUS.

NORTH BIRMINGHAM, ALA.—The People's Home Telephone Company's exchange was destroyed by fire recently. Loss about $1,500, partly covered by insurance.

LONDON, ENG.—A number of towns on the northern coast of France are now connected with London by telephone, the charge being $2 for three minutes' talk.

CHICAGO, ILL.—The Illinois Tunnel Company has now in service over 8,000 trunk line telephones, and is rapidly extending its service in every direction. President Wheeler predicts that within another year the company will have about 25,000 telephones in service.

LEXINGTON, KY.—The East Tennessee Telephone Company has been sued by the city of Lexington through the firm of Hunt & Hunt for $949.89 back taxes, not including penalty and interest alleged to be due upon its franchise. The petition recites that the franchise was assessed at $15,217 for 1899 and $15,000 for the years 1900 to 1903 inclusive, and states that the defendant company failed to pay taxes for those years.

PORTLAND, ME.—The Moosehead Telephone Company has applied for permission to build its line along the route of the Canadian Pacific Railway.

NORWOOD, MINN.—The Norwood Young America Telephone Company's exchange at Wauconia was almost totally destroyed by the cyclone which passed through this section recently.

HASTINGS, NEB.—The Independent Telephone Company is making preparations for erecting a new exchange building to cost $10,000.

OMAHA, NEB.—The Mutual Telephone Companies operating in Garfield County have formed an association with headquarters at Burwell.

YORK, NEB.—The Independent Telephone Company is issuing a new directory for York County, which shows 1,400 subscribers. This is one of the largest independent companies in the State and has one of the best equipped telephone exchanges and gives entire satisfaction. Nearly every farmer now has a telephone, and with the rural mail service, farm life in York County is not as monotonous as a farmer's life years ago.

ERIEVILLE, N. Y.—The Erieville branch of the Newton Telephone system is ready for business.

OSWEGO, N. Y.—The Ontario Telephone Company will shortly issue a new directory which, besides being the most complete ever issued, will also show the great strides this company has made during the last six months.

HOBOKEN, N. J.—The Erie Railroad Company has applied to a number of telephone equipment houses in Cleveland and the east for estimates on the cost of installing a system between Cleveland and New York. The telegraph system of the road has, particularly of late, been greatly overtaxed, and it is the intention of the company eventually to extend the telephone system to Chicago, the approximate entire length being 639 miles. It is estimated that the cost will be in excess of $100,000.

BRANTFORD, ONTARIO.—Recently the special committee of the council of the telephone service resolved by a vote of four to two to commence the construction of a civic telephone system at an estimated cost of $37,000. This matter has been under consideration for several months and the committee visited Port Arthur and Fort William in connection with the proposal.

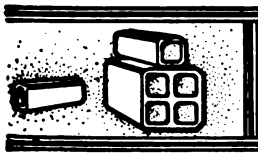
POTTSVILLE, PA.—The Mahoning & Mahantongo Telephone Company, a concern that will do business throughout the farming regions of Northumberland, Dauphin and Snyder Counties, will be organized in the near future.

BROWNSVILLE, TEX.—The city will establish a telephone system. Address the mayor for information.

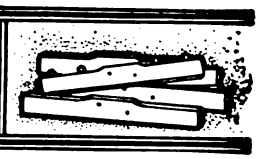
EL PASO, TEX.—The receiver has been discharged in the bankruptcy case of Mrs. Anna M. Brett, who has for several years been promoting the establishment of an independent telephone system in El Paso, and it is announced that that system will now be completed as fast as possible.

EL PASO, TEX.—The city council has under consideration an application made by R. A. Wooldridge and C. F. Wren for a franchise to establish a new telephone system in El Paso, at a cost of not less than $100,000.

KENOSHA, WIS.—The forthcoming directory of the Citizens' Telephone & Telegraph Company will embrace a list of subscribers to the Independent telephone companies of about twenty-five surrounding towns. The Independent telephone system of the neighborhood is exceedingly prosperous and growing rapidly.



New Construction in the Field



TORONTO, CANADA.—The Columbiana County Telephone Company is anticipating re-establishing an Independent telephone exchange here connecting with the Phoenix and United States lines.

LATON, CAL.—A new farmer's telephone line is being established east of Laton.

SAN DIEGO, CAL.—The Home Telephone Company is rapidly completing its line plant and exchange building.

LANARK, ILL.—The Lee County Telephone Company will rebuild its system and will place the wires underground. It is estimated that the change will cost about $75,000.

MARSHALL, ILL.—The Westfield Telephone Company will install 500 feet of aerial cable in the business part of the town.

PEORIA, ILL.—The Citizens' Telephone Company will install a line from this place to Roanoke and into East Peoria.

SOUTH McALESTER, I. T.—The South McAlester-Eufaula Telephone Company has installed a new switchboard.

OSGOOD, IND.—A telephone line is being built from here to Dewberry.

SOUTH WHITLEY, IND.—The Farmers' Mutual Telephone Company will install a new system here.

CHESTER, IA.—The Chester Standard Telephone Company, of Waukon and Dubuque, is installing a complete up-to-date long distance telephone exchange system in this place.

WEBSTER CITY, IA.—The Martin Telephone Company is installing another section on its switchboard. The new section will contain 400 drops.

ASHLAND, KAN.—A movement is on foot to put in a telephone line from Ashland to Lexington and probably on to Bucklin.

LEWISTON, ME.—The White Mountain Telephone Company is making large extensions to its system.

PENTWATER, MICH.—An automatic exchange is being installed in this town.

STILLWATER, MINN.—The Northwestern Telephone Company is putting in about 10,000 extra feet of cable.

MOOREHEAD, MINN.—The Red River Telephone Company is extending its lines into Clay and Cuss Counties from this town.

WELDON, N. C.—The Home Telephone Co. will make improvements and extensions to its system here. F. C. Toeplemann is general manager.

GENEVA, N. Y.—The Geneva Telephone Company is extending its lines into the county districts.

NEWBURGH, N. Y.—The State Line Telephone Company is constructing lines into Dutchess County and will connect with Wetchester County and the Colonial Telephone Company at Newburgh.

OWEGA, N. Y.—A telephone line connecting Newark Valley with Foster is nearly completed. The line will run to Union Center to connect with the York state line.

PINE PLAINS, N. Y.—The State Line Telephone Company has completed its lines to connnect with the Sharon Company. The company is also building a line to connect Shekomeko and also a line from Poughkeepsie and Arlington.

AKRON, OHIO—The People's Telephone Company will construct lines into the country district surrounding Barberton.

CLEVELAND, OHIO.—The United States Telephone Company has started the construction of new toll lines at Columbus and Medina. A line will also shortly be started between Ravenna and Alliance.

KENTON, OHIO.—The Kenton Telephone Company will install a new two position toll board. New copper toll circuits are being strung between Kenton and Columbus and Kenton and Bowling Green.

PORTSMOUTH, OHIO.—The Home Telephone Company is rapidly pushing its line, which passes between Portsmouth via Mabee, to completion.

WEST UNION, OHIO.—The Independent Telephone Company, doing business in Scioto, Pike, Adams, Jackson and Ross Counties, has bought a telegraph line of the Western Union Telegraph Company and will install a system of telephones in these counties. A line to connect with the Clinton, Highland and Clermont County system will be built.

MEADVILLE, PA.—The Meadville Telephone Company will build a line between Meadville and Cochranton. When this line is completed it will give the Meadville company a through copper circuit to Pittsburg and also direct connection with Franklin, Oil City and Titusville. John H. Wright is general manager of the company. The company has over 1200 telephones in use in Meadville.

MUNCY, PA.—A telephone line will be built from this town to Unityville.

RICHMOND, PA.—A new telephone line is to be established between Conneaut and Richmond. The line will soon be in working order.

COLUMBIA, TENN.—The Citizens' Telephone Co. has let the contract for the building of a new line from this city up the Bear Creek pike to Losea and points beyond. It is also projected to be extended to Hardison's Mill and Rally Hill.

LEXINGTON, VA.—The Lexington Mutual Telephone Co. will improve and enlarge its exchange here at a cost of $5,000.

SUFFOLK, VA.—The Nansemond Telephone Company, of Suffolk, is putting in new telephones. Long distance communication can be had with the surrounding country and this territory is being rapidly extended.

BETHESDA, W. VA.—The Belmont Telephone Company will build a system in this town.

TRADE NOTES.

THE STERLING ELECTRIC COMPANY, Lafayette, Ind., has just completed a large export order for London, England. This company reports a steady growth in export business.

THE S. H. COUCH COMPANY, 156 Pearl street, Boston, Mass., is manufacturing a fine line of magneto telephones and apparatus, and all exchange managers looking for the right article at the right price should communicate with the firm and secure a copy of its catalogue.

FRANK B. COOK, of Chicago, has recently sold an addition to the distributing frame of the Auburn Telephone Company, of Auburn, N. Y., which was manufactured for him. The frame is Cook's type L, equipped with a No. 44 protector. The addition of 400 lines brings the total capacity up to 2,050.

Digitized by Google

THE NATIONAL TOLL TICKET Co., Albion, Mich., has recently issued catalogue No. 2, which describes the tickets this company manufactures. There are samples of 12 varieties of toll tickets beside trouble tickets. This firm will also be pleased to furnish estimates for printing special forms and subscribers' lists.

A. GROTHWELL, of 136 Liberty street, New York, and 26 Montgomery street, San Francisco, has issued a booklet describing "Mogul" preservative paints, compounds and varnishes. The preservative paint is specially prepared to prevent dry rot of poles at the butt, bolt holes, gains or any other point that is liable to be affected. It is a quick dryer, water-proof, ice, frost and snow-proof, and affords ample protection for cables and battery cells in damp places. "Mogul" armature varnish is especially good for fine work in insulating cable boxes and other places requiring insulation.

THE MONARCH TELEPHONE MFG. Co., of Chicago, has issued an attractive booklet entitled "The Secret of Our Success." It contains a number of testimonial letters received from users of Monarch apparatus and also gives illustrations and descriptions of new features found in the telephones manufactured by this company. The title page indicates that the success of the Monarch Company is due to an honest endeavor to make perfect telephone apparatus, to always have its equipment up to date and to treat its customers in a fair and square manner. Such a policy as this should bring success to any one.

THE BAIRD MANUFACTURING Co. (maker of Baird Pay-Stations), has just brought out a new Permanent Adjustment Invisible Joint Telephone Transmitter Arm which is finding great favor wherever it is shown. That there is genuine merit in this arm is proven by the fact that after being attached to a machine and given 1,000,000 motions, the friction of the arm is not injured in the slightest, but it will hold a transmitter exactly where it is put. These arms are beautifully finished and telephone companies may secure them by specifying Baird Transmitter Arms in their orders for telephones of their usual manufacturer.

THE MEASURED SERVICE Co., 153-159 So. Jefferson street, Chicago, is putting on the market a measured service meter of entirely a new type. Each subscriber registers his call and at the end of each month instead of sending around a collector the subscriber is called up and asked to "turn the lever forward." In doing so a statement of the number of calls on the meter is sent over the wire and recorded on a tape, by the Morse code, at the central office. The system has the advantage of allowing the subscriber to know how many calls he is making and does away with the detail of keeping track of the calls at the exchange and yet at the same time everything is completely under the control of the central office. The company will be glad to give interested parties any further information.

THE AMERICAN ELECTRIC TELEPHONE Co., of Chicago, have just received an order for the building of a combination long distance and rural line switchboard to be installed at Hopkinsville, Ky., by the Ideal Construction Company, of Lima, Ohio. This order is regarded as an important one from an engineering standpoint owing to the special requirements which it is necessary to meet, for this switchboard must be provided with means for trunking to and from both the Strowger Automatic Exchange and the Globe Automatic Exchange. At the same time, service must be given on the American Company's system of selective party lines. Thus, it will be observed that the trunking and cord circuit arrangement must be such as to permit of interconnection between magneto bridging lines, party line selective, Globe Automatic and Strowger Automatic lines.

THE CENTURY TELEPHONE CONSTRUCTION Co., of Buffalo, N. Y., has recently increased its capital stock from $100,000 to $500,000. This increase was made necessary on account of the rapid growth and development of the company's business within the last few months. The entire increase of capital stock will be fully paid up. This company manufactures an improved style of apparatus which, from the number of voluntary testimonials, is filling a long-felt want. The sales of the Century switchboards, telephones, and various other pieces of apparatus are increasing in an unprecedented mannner. The directors of the company will be: A. D. Bissell, president People's Bank, Buffalo, N. Y., and vice-president of the National Banking Association; Theodore S. Fassett, of the Smith-Fassett Co., lumber dealers, Tonawanda, N. Y.; Martin Carey, of Bissell, Carey and Cook, attorneys, Buffalo, N. Y.; and B. G. Hubbell, president of the Consolidated Telephone Company, Buffalo, N. Y. The men associated with the company are among the best financiers in this part of the country, and are enthusiastic over its organization. In fact, there are few telephone companies that have so prominent a personnel in its list of stockholders as is embraced in that of the Century Telephone Construction Company.

THE AMERICAN CONDUIT COMPANY, of Chicago, Ill., has an attractive and interesting exhibit in the court of the Palace of Electricity at the World's Fair. This exhibit is worthy of the attention of anyone interested in underground electrical construction. The exhibit demonstrates the high class of underground construction obtained by the use of their bituminized fiber conduit. It consists of a portion of a manhole showing the neatness of construction possible with this conduit at the entrance of the manhole. Also a portion of the underground system with the street, the earth and the concrete filling removed to expose the ducts themselves. This portion brings out one of the advantages of the long lengths, namely, the few joints in the system, and also shows the perfect and permanent alignment secured and the sealed joints, a feature invented and introduced by this company.

Another portion of the exhibit shows the open trench with the various layers of ducts as they appear in the course of actual progress of the construction work.

There are in addition to the above some bends of various radii and diameter and some lengths of conduit. Also some interesting photographs showing construction work in various cities where bituminized fiber conduit has been used. An attractively furnished office or reception room is provided for the convenience and comfort of those who are directly or indirectly interested in electrical conduits, and visitors will secure the courteous attention of C. M. Ripley, electrical engineer, in charge of the exhibit, who seems always delighted to give information relative to bituminized fiber conduit.

The company hopes to give some interesting demonstrations in the way of tests showing the high insulating qualities of this conduit.

FOR SALE

Advertisements under this head, $1.00 for 25 words or less for each insertion. Prepaid.

WANTED TO SELL.—A telephone system operating in eight counties in a western State, with five small exchanges. Good city connections and a first-class investment. Easy terms to the right party. Address, Box 239, AMERICAN TELEPHONE JOURNAL, 116 Nassau Street, New York City. 239

WANTED

Advertisements under this head, 25 cents for 25 words or less for each insertion. Prepaid.

WANTED you to know that I can locate your cable troubles. Charges moderate. Address C. E. NICHOLAS, Columbus, Ohio. 226

WANTED to correspond with investor for the advancement of Independent telephone interests in Eastern Iowa. Good territory; small capital. Address Box 250, AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 250

WANTED—Second-hand generators and ringers in good condition; give make, general condition and price asked. Address Box 223, AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 223

WANTED—Good mechanical draughtsman; must be perfectly familiar with telephone work. Address Box 243, AMERICAN TELEPHONE JOURNAL, 116 Nassau St., New York City. 243

POSITION wanted as manager or assistant of exchange, 400 to 1,000 subscribers, within 150 miles of New York. Experience with Bell and Independent companies in all lines, construction, repair and maintenance, switchboard, lines and instruments. Address Box 249, care of AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 249

WANTED—Position as manager or superintendent of telephone company; East preferred. Eight years' experience as superintendent of largest plants. Best of references. Address Box 248, AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 248

WANTED—Bright young man of good appearance, who understands thoroughly technical telephony. One who has worked in the field preferred. Must be able to write descriptive booklets on telephone apparatus. Exceptional prospects for the right man. Address Box 242, care of THE AMERICAN TELEPHONE JOURNAL, New York City. 242

POSITION WANTED—As manager or superintendent of telephone company; have had seven years' practical experience in all branches of the business. Address Box 247, AMERICAN TELEPHONE JOURNAL, 116 Nassau Street, New York City. 247

WANTED.—At half value, fifty first-class second-hand compact series telephones (magneto) from some independent company that has changed to common battery. Must be from one of the best manufacturers. Address, Box 238, AMERICAN TELEPHONE JOURNAL, 116 Nassau Street, New York City. 238

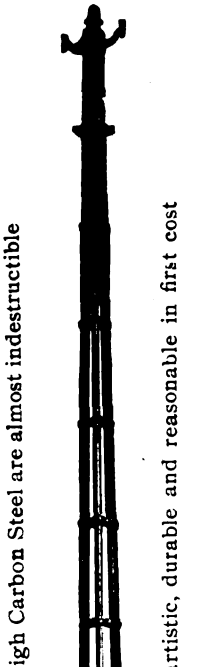
The Open-Wireless Telephone Plant

is an all-cable plant; that is it has no open wire (bare wire) or cross arms, and when supported on steel poles

DEPRECIATION IS ALMOST ELIMINATED; MAINTENANCE REDUCED TO A MINIMUM



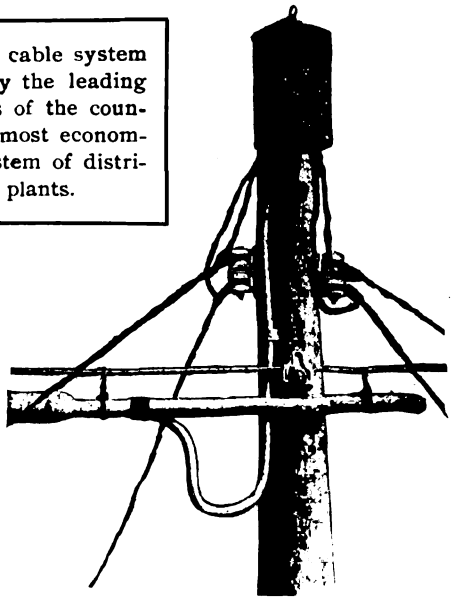
POLE OF THE FUTURE

Poles made from High Carbon Steel are almost indestructible

The Steel Pole is artistic, durable and reasonable in first cost

No poles to rot.
No cross arms to rot.
No glass insulators to break.
No crossed wires to interfere with service.
Trees do not interfere.
Sleet storms lose their terror.
No unsightly cross arms and wires on the streets.
No bare wires to break and fall on electric light wire and kill some one passing by.

The multiple tap cable system is acknowledged by the leading telephone engineers of the country to be by far the most economical and durable system of distribution for telephone plants.



THE SYSTEM OF THE FUTURE

The undersigned is a pioneer in the multiple cable distribution and makes a specialty of

Planning Cable Layouts
Multiple Cable Distribution
Equipping for Party Lines
Rate Raising, Etc., Etc.
Plans, Specifications and Supervision of Installation of Complete Telephone Plants

WILL GUARANTEE TO INCREASE THE DIVIDENDS IN 99 TELEPHONE PLANTS OUT OF EVERY 100

Engineering, constructing and putting plants on a dividend-paying basis a specialty.

There are many serious mistakes made in the selection of apparatus, construction and maintenance of telephone plants due to lack of experience.

There are many leak holes in a telephone plant unless properly watched.

With proper co-operation on part of owners of telephone plants, I will guarantee to make any Telephone Plant pay dividends or increase your present earnings. Can refer you to a number of telephone plants where I have saved thousands of dollars in first cost of the plant, increased the earnings, improved the service, decreased the operating expenses by installing proper apparatus in the proper way and properly organizing the working force. Can furnish expert engineer, wire chief, auditor, solicitor, chief operator, each a specialist in his line.

Bituminized Fiber Conduit
For Underground Construction

Combines the **good features** of other conduits. **Eliminates** the **bad features** existing in many kinds. **Has valuable features** not found in any other ducts. :: ::
Made in 7-foot lengths with male and female joints, making construction very rapid and simple, with consequent low cost. :: :: ::
Alignment is perfect and permanent without tedious care and skill required in laying of butt-joint conduits.
Users are astonished by the ease and rapidity with which cables can be drawn in, and this without the slightest scratching or injury to the lead covering thereof.
Made in sizes from 1-inch to 10-inch diameter. ::
Bends of any radius and any angle. :: ::
Write us for further information and prices, stating sizes and quantities required. :: :: ::

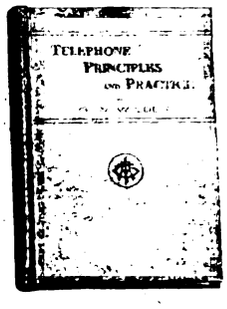
THE NEW TELEPHONE BOOK



By G. W. WILDER, Ph.D.,
Professor in Telephony
Armour Institute of Technology

This book is strictly up to date and complete in every respect. It deals with all of the ins and outs of telephone apparatus. Profusely illustrated with drawings and half tones. Instruments, switchboard and cord circuits with detailed descriptions, enable anyone to thoroughly understand all the problems met with in telephone practice.

CONTENTS

CHAPTER.		CHAPTER.	
I.	Magnetic Action.	XVI.	Instruments and Instrument Circuits.
II.	The Centimeter-Gram-Second System.	XVII.	Party Lines.
III.	The Electric Current and Magnetism.	XVIII.	Exchange Systems.
IV.	The Solenoid.	XIX.	Switchboard Circuits.
V.	The Production of an Electrical Pressure.	XX.	Switchboard Details.
VI.	Sound.	XXI.	Complete Switchboards.
VII.	Early Forms of Telephony	XXII.	Capacity.
VIII.	The Telephone Receiver.	XXIII.	Common Battery Systems
IX.	The Transmitter.	XXIV.	Selective Party Lines.
X.	Induction.	XXV.	Location of Exchanges and Pole Lines.
XI.	The Induction Coil.	XXVI.	Poles.
XII.	The Magneto Generator.	XXVII.	Wire.
XIII.	Ringers.	XXVIII.	Construction of a Wire Plant.
XIV.	The Generator Shunt.	XXIX.	Cables.
XV.	The Hookswitch.	XXX.	Lightning Protection.
		XXXI.	Line Disturbances.
		XXXII.	Electrical Testing.

THE AMERICAN TELEPHONE JOURNAL

Out of the Business, Still Needs the Journal

Here is a letter from a subscriber who is engaged in other work, but says he still needs the Journal:

> "I have retired from the telephone field to engage in the mercantile business. I have been local manager of the Union Telephone Co., at Mount Pleasant, Mich., and district manager for northeastern territory for four years, and while giving up the work, I still retain the Independent spirit. Kindly notify me of expiration of my subscription for I do not wish to be without the Journal."
>
> H. E. JEFFERY,
> Auburn, Ill.

We think this letter is as good as a page of reasons why every telephone man should have the Journal.

Our System is
"Just What You Need"
FOR
GENERATOR CALL PARTY - LINES -

Single wire **Ground** Lines, Straight Metallic or "Divided Circuit" Metallic Lines.

When Switchboard Drop falls, **it means** that some subscriber has called "Central."

Drop does **not** fall when subscribers call each other, as **Alternating** current is used for this, and our Selective Central Relay does **not** respond to Alternating current.

When Subscribers call "Central," **Direct** current is used, therefore they do **not** ring Telephone Bells along Line, but **instantly** throw Drop at the "Central" desired (either of Two "Centrals").

We advise Managers, Stockholders, Subscribers and Central Operators of party lines to send us their address. We CAN SAVE you ALL—Time, Labor, Wear and Tear on Apparatus, Nerves and Temper.

REMOVE from your Switchboard your Cow, Sheep, Sleigh and Extension Bells. Use Drops made by the manufacturer of your Board in this VALUABLE space, connect Drops to our Selective Central Relays, and give your Subscribers **better** service than is POSSIBLE any other way.

You can use the Telephones you have now.

TELEPHONE PRACTICE

TAUGHT BY MAIL

Under the direction of widely known Telephone Engineers and Technical Instructors. ∴ ∴ ∴ ∴ ∴

No matter what your particular branch of telephone work may be, you ought to know the general principles underlying all telephone practice. Our textbooks have been prepared by the foremost telephone engineers in the country and the instruction is thorough and scientific, though easy to master. ∴ ∴ ∴

Among the Subjects Covered in the Course are

Elements of Electricity.
The Electric Current.
Theory and Types of Dynamo-Electric Machinery.
Electrical Measurements.
Sound: Batteries; Alternating Currents; Electro-Static Capacity.
Telephone Lines: Circuits; Line Construction; Open Wire Lines; Underground Cable Lines; Terminal Points; Distributing Points. Submarine Cable Lines. Retardation Coils; Pupin's Load Coils.
Telephone Exchange: Switchboards; Exchange Wiring; Power Apparatus; Primary and Secondary Batteries; Charging Machine; Special Machines.
Operation and Maintenance: Toll Boards and Lines; Long Distance Switchboards; Direct and Party Lines; B. W. C. System. Common Battery System. Locating Faults.

We also offer 60 other courses in Engineering, and until October 31st will grant three great special inducements. This is the time for you to act. Fill out the coupon and *MAIL TO-DAY.*

.....**Cut Here**.....

Please send me full information regarding your four special offers as advertised in The Am. Tel. Journal (Oct. 1st).

INDEPENDENT LOCAL AND LONG DISTANCE TELEPHONE

LAFONTAINE, INDIANA, Sept 13th 1904

Swedish-American Telephone Co.,
Chicago, Ill.

Gentlemen:-

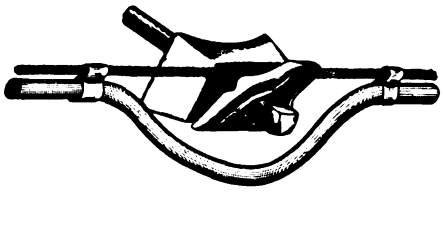
We have been using your instruments and switchboards since May 1902 and are now ready to tell you they are just as good as you represent them to be.

We have 500 telephones installed, 400 of which are on party lines of 8 and 12 and one man has been able to keep them in good working order at an average of 2 days per week.

We heartily recommend your instruments and your way of doing business.

Yours truly.

LaFontaine Tel Co
by L B Morris
Mgr



OUR MESSENGER HANGERS

are unbreakable, easily installed and lasting.

THEY ARE CHEAP

Because we make them in large lots, thus cutting down the cost of material and labor.

ONE INSTANCE OF THEIR SUPERIORITY

The Consolidated Telephone Co., of Buffalo, N. Y., formerly used the old "L-Shaped" hangers. One of these broke where it was bent, allowing the cable to drop, just escaping an employee's head, and putting an extraordinary strain on the cable. **The Company then equipped its Entire Plant with our Hangers, and has used them exclusively since that time.**

Write for sample and prices and our complete catalogue of Line Specialties and Telephone Supplies.

THE MAN OF THE HOUR IN THE INDEPENDENT TELEPHONE MOVEMENT

By ANTONIO WEST.

JAMES B. HOGE, the newly elected president of the National Independent Telephone Association of America, is one of the most interesting figures in the Independent field. His association with Independent telephony started in 1898, and since that time he has been using his best efforts to place the companies with which he has been connected upon a sound financial basis. Mr. Hoge is also a typical illustration of the American business man, and in both connections a short biography may be interesting to our readers.

He was born near Flushing, in Belmont County, Ohio, on December 20, 1866, his parents being Byron M. Hoge and Tamzen L. (Merritt) Hoge. The early part of his life was spent upon his father's farm, where his father still resides, his mother being deceased. The Hoge family can trace ancestry back to a long line of sturdy Scots, the first of whom came to America as early as 1650 and settled in Virginia. In the latter part of the 17th century the family moved to Ohio, where it has since remained.

James B. Hoge.

Mr. Hoge secured his early education at the village school near Flushing. When 16 years of age he took up the study of bookkeeping, telegraph operating and other railroad work, employing his services, when possible, by delivering messages for the Western Union Telegraph Company at Flushing. At 18 years of age he accepted a position as night telegraph operator for the Cleveland, Lorain & Wheeling Railroad at Bridgeport, Ohio, where he remained for two years, occupying various positions with this railroad and its allied interests. In 1888 Mr. Hoge was transferred to Lorain as chief clerk for the Cleveland, Lorain & Wheeling and Nickel Plate Railroad, which position he filled for nearly three years, when he retired from the railroad business and organized the Lorain Savings and Banking Company, of which he became secretary and treasurer. In 1894 he was elected secretary of the Lorain Chamber of Commerce. During that year arrangements were made for the Johnson Steel Company to move their works from Johnstown, Pa., to Lorain. Besides this, the Chamber of Commerce negotiated a number of improvements for the city, among other things undertaken being that of securing a telephone company for the thriving village, then having a population of about 6,000. The Bell Company refused to build an exchange unless they were guaranteed fifty subscribers at $54 per year. Although the basic patents had not yet expired, the subject of this sketch organized a syndicate to build an exchange, with the result that it was placed in operation before the close of that year. At the present time this exchange has over 1,600 subscribers, and the Bell less than 15 telephones in that city.

While secretary of the Lorain Savings and Banking Company, Mr. Hoge became connected with the Everett-Moore syndicate. The head of this organization recognizing his ability, in 1898 made him secretary of the U. S. Telephone Company, when he moved to Cleveland, resigning his position in the bank he had organized and made a prosperous institution. Mr. Hoge still holds the position of Secretary of the U. S. Telephone Company, and also that of vice-president of the Federal Telephone Company, to which position he was elected later on. He organized the Citizens' Gas and Electric Company, of Lorain and Elyria, consolidating the electric light and steam heating interests of those cities into one organization, later selling them to the Union Natural Gas Corporation, of Pittsburg when natural gas was found in Central Ohio.

Mr. Hoge is a member of the Union Club, of Cleveland. He is a whole-souled gentleman, and, although a busy man, is always ready to give attention to those who desire to consult him. Never having the time nor the inclination to take a hand in political affairs, he has never held a public office.

In 1891 Mr. Hoge was married to Anna Wallace, of Lorain, and three children have blessed the union—Rachael, aged 12; Eleanor, aged 10, and Wallace, 2 years old.

Success or failure in a business enterprise is nearly always traceable to the governing head. No matter how good or how well designed the institution may be, the selection of the dominant power is a task which requires a very great deal of foresight and knowledge.

The National Independent Telephone Association has secured in Mr. Hoge a man with an indomitable will and energy, who is well able to pilot its affairs. The amount of work to be done in the direction of the association's interests could not be placed in better hands than in those of its new president. Co-operation is the keynote of success, and, as was recently said by Senator Flynn, its great value will come from quick organization. Mr. Hoge is thoroughly capable of organization, and if he secures the right sort of co-operation, the success of the National Independent Telephone Association of America is assured.

PLANNING A TELEPHONE SYSTEM

By Samuel G. McMeen.

I SUPPOSE a good many of you are saying: "I hope it won't be a long story; I hope he has not put in a lot of figures." Well, it isn't; and I haven't.

If all the towns were about alike in the ways their people are distributed over the town's territory; if the prices of materials did not change; if no improvements were made in machinery and supplies; if there were reasonable expectation that styles and fashions in telephone things would be constant; if it were just as easy to dig holes and ditches in the ground in one town as in another; if the people in one town were just as wealthy as in any other, and if the long distance line systems were now complete enough to cover the continent, then planning a telephone system would be easy.

In such ideal conditions a person with the telephone fever might place an order with the manufacturers for "one standard equipment of so many stations," and with the contractors for "one standard system of so many lines." And there would be a great final gratification in the fact that the real investment would be found very much like the original estimate; a condition which happens so seldom as to be quite striking when it does occur.

A certain gentleman who wanted to overhaul the plumbing in his house declined to give money to charity when requested. His reason was that he was about to spend several thousand dollars on his house, as the estimate alone was $350. Some of the people who have been attracted to the telephone business because it seemed to be cheap and easy may drop a tear of sympathy.

It is no news to say that a plan for a telephone system, whether it includes merely an exchange for a town or a toll line system as well, must plan to build the system at the lowest possible cost in investment, and the lowest possible costs of operating the thing when done, keeping it in operating condition, replacing parts of it when they are worn out, and replacing other parts at just the time it is wisest to do so to get the advantages of newer and better ways. There is a real difference between the annual cost of keeping the thing in operating condition, ordinarily called "maintenance," and the annual cost of replacing parts which are no longer serviceable, due to their having worn out or become superseded by something better.

It has been supposed that the cost of operation depends mostly on good management, and this is probably true; but the more recent development of automatic apparatus is causing some of the old-timers in the business to sit up and take notice. I do not mean to say that it is always cheaper to make the connections by machinery than by hand, but that there is much more reason now to believe that such a result may be reached than there was five years ago.

To accomplish the lowest cost in investment does not always mean lower annual costs in maintenance, depreciation and operation. You have seen systems which impressed you as having come into being largely by accident; in some of these a little inspection of the accounts will show such annual sums of unnecessary outlay as are really adding substantially to the effective investment. As a fundamental principle, it is supposed to be best to run your business on your own capital; but there are many telephone exchanges in which borrowed money applied in betterments would pay interest on itself, and a substantial profit besides. This because of the greater saving, even though the borrowed investment did not increase the gross revenue at all.

Differences of opinion among telephone men as to the right number of offices to establish in a fairly large city have been supposed to be due to the natural tendency of men not to agree with each other. In large cities in Europe there exists a liking for one central office, with a large number of lines. In the larger cities in the United States it is quite usual to prefer a number of offices.

The explanation is very simple. As telephone systems are now built, a very large part of the annual cost of merely owning the system a year at a time is in the wire plant; and this in a large city of only reasonable density of population varies strikingly with different arrangements of the lines in offices; when they are centered in one office it is quite the rule that the average length of line is greater than when part of the lines center in one office and other parts in others. It is true that where there are several offices in a city these must be joined to each other by trunk lines; but as trunk lines are so heavily used, it is never true that the total amount of wire in subscribers' lines and trunks is as great with several offices as it is with one.

In the cities of Europe a great many more people live in a given space than here. The lines are therefore shorter. Labor is cheaper. And in some cases a one-office arrangement was chosen because the engineers made a bad guess.

If there were no other reasons to be considered, more than one office in a town would generally be cheapest; but, fortunately or unfortunately, the cost for operators is always greater in the several-office arrangement than in that of one office. But in any town whatever, an arrangement can be found in which the total cost of owning and operating and keeping up the lines and offices, when taken as a whole, will be the least. In laying out a system of reasonable size, finding the number of offices and where they ought to be is one of the important considerations; and is a condition which, if poorly established, can absorb a surprisingly large amount of money each year.

In a small city, one office is nearly always the best arrangement, and in the past it has been customary to assume that this would be so, and to plan accordingly, leaving the consideration as to what future arrangement might be best to be taken care of by the future. It has resulted—and will result again—that it is found that the one-office originally established is in a surprisingly bad place when the day does come that others must be opened. By being in a bad place I mean simply that when additional offices are established, this first one may be found by its location to be adding to the annual cost of owning, operating and keeping up the system.

In establishing any office, even if the exchange be small, wisdom of choice is required with reference to the location of the building, its size and its character. I have pointed out that the location of the building has an effect on the length of lines. It also has an effect on the fire risk, and sometimes there is also a risk from high waters. Service has been interfered with by fire in an adjoining building, even though there was no immediate danger to the central office itself. Whether the building be owned or rented, the arrangement of the apparatus in it is best when not only the exact location of future additions is taken into account, but when a growth of unexpected amount is provided for. Instances have occurred where a plan otherwise good has been found to be very bad beause the growth was great enough to carry the switchboards against a wall which could not be removed and in which direction the building could not be extended.

The best central office arrangement, other things being equal, is that which carries the entering cables, and those which are joined to them, through their runs with the greatest directness, and therefore at the smallest cost. In the larger offices a saving of a foot length in a cable run is a very considerable advantage.

As to choice among the many types of equipment now available, one may gain a great deal of information from the manufacturers, as they will tell you all about the good points of their own manufacture, and sometimes about the bad points of that of others. A great deal of light is thrown upon the situation, and the embarrassment of choosing is much relieved by the application of a few simple but exacting tests to samples submitted by the manufacturers. In every case the prospective purchaser has a great advantage if he purchases in accordance with definite specifications covernig his exact needs, because those things not only assist the manufaturer in knowing exactly what is called for, but

Digitized by Google

assist the purchaser in protecting himself in case the things delivered are not satisfactory.

In all except the very smallest offices, careful planning of the equipment will usually make a saving in the expense of operators. Where local and toll duties devolve on the same operator during quiet hours, economy and convenience may both be accomplished by an intelligent arrangement of the switchboard locations.

Since the first introduction of lead covered cables there has been a decrease in the use of bare open wires. Except as to the cost of the system, there is no reason why all wires should not be in cables. Where the development is very dense, it is really cheapest to carry cables directly into the buildings, but in residence districts it is best to strike a happy medium between all cables and all open wire. Because a subscriber should be connected as soon as his contract is secured; because to do so means a line must be ready for him in advance; the future development of the residence districts can be guessed with less exactness than the denser districts, it is necessary that the multiple tap method of distributing cable conductors be used at least in some degree. If intelligently applied, the multiple tap method also reduces the wire plant cost below that of the more cumbersome open wire treatment of line ends, with its attendant maintenance expense, and annoyance of service interruption.

Like many other good things, however, the multiple tap system may be practiced to excess. There is no involved mathematical formula which will answer the multiple tap question for a given town, but it is possible and necessary as well to make comparisons between the costs of several arrangements for a given territory. And these comparisons should be made with care enough, and patience enough, to make certain that the best way has been chosen when a conclusion really is reached.

In recent times quite substantial changes have taken place in the costs of things which go to make up the wire plant. It is gratifying that this is so, because this part of the system has always been predominant in using up investment. No matter how cheap, however, the materials for line construction may become, the proportion of labor cost to the total cost of the constructed thing will remain large. As a comparison, it may be interesting to know that the equipment for central offices and subscribers may be installed for from 5 per cent. to 10 per cent. of its cost, while very many of the elements of line construction cost as much for labor as for material. A thing which the constructor, therefore, must plan toward is the elimination of labor wherever possible.

There are two good results of such watchfulness; one is the natural keeping down of the total cost, and the other a higher final depreciated value. For if it costs a dollar to put a dollar's worth of copper in place, 50 per cent. is more than you can ever get out of it by selling it as junk. This is one of the reasons why placing cables under ground has had such an effect on annual telephone costs. Two cables just alike, one on poles and one in ducts, may reasonably be expected to have an annual depreciation cost of several to one in favor of the underground cable; and this without taking into account the superior lasting qualities of the structure which cares for the latter.

Without citing further examples, I think I may generalize by saying that it is necessary to apply these and other simple rules to the planning of a telephone system for a town, and to lay out the course of action which, when methodically pursued, will bring the originate estimate and the actual cost reasonably close together, not only as to the first investment, but to the annual charges when in service.

Not the least important thing in preparing to make such a plan is to get on the ground, and become saturated with the local facts. It is gratifying to find by experience that an outsider may get such a knowledge of a town by tramping over it, by consulting public records, and by diligent inquiry from those who know, as to enable him to compile field notes almost as accurate as to the things he needs to know as those taken by the civil engineer in laying out a railroad.

By this I do not mean merely finding out what is under the pavement, and where there are alleys and where none, because these are simple matters. The important thing is to get so many facts about the town as to enable correct guesses to be made as to where the future growth of the town will occur, about how fast it will go on, and in what direction it will push; what kind of houses will be built in this quarter, and what kind in that; the probable change in the business area, and its present tendency of expansion; is the street railway system going to develop this residence area more than that, or will a new district spring up next year? One of the greatest helps toward reasonably correct conclusions in this plodding sort of investigation is to cut it up into such small pieces that the great quantity of estimates will prevent a serious error being introduced by a few bad ones. In five hundred guesses the influence of one wrong one is not only relatively small, but each guess is easier to make with truth.

In all of these cases the elements of estimate are made with a view to determining not so much what the town is to-day, but what it will be at the end of a selected period. It is not difficult to build a system for the present for a town of known conditions. It is more difficult, and more important as well, to make the plan complete for the town which is to be, because it is that town which the system must serve. The only difference between the best method of planning to-day and those which have been used heretofore is that the later method uses more care in details, and realizes more fully the kinds of mistakes which are likely to be made. Perhaps it reflects little credit on the engineers, but it is distinctly to the advantage of their employers that they have made almost all the blunders that are possible to be made; and it goes without saying, of course, that a man of reasonable common sense will not make the same mistake twice. If it were only long-lived enough, this tendency might result in quite a perfect telephone condition being reached.

So far as I have described the manner of such planning, it has been in the way of accomplishing minimum costs. It goes without saying that the minimum cost plan must involve due consideration of the quality of service to be given. A plan which will not make good service falls short of its mission, quite as would a manufacturing property which would not turn out good product. This brings me to the very important and widely neglected feature of planning all parts of a telephone system, whether in a town or between towns, so that it may ultimately form a part of a successful continental telephone system. I do not mean by this merely that a consolidation of telephone interests may take place. What I do mean is that any plan falls short of its mission which does not involve making all elements as nearly as may be such as will be serviceable and useful when the continent is covered with a complete network of long distance lines, connecting exchange with exchange. You may answer that the day of such a system is so far away that it is foolish to waste money on it now. My answer is that the day in question is not so far away as many are thinking, and that it does not always mean an excess expenditure to take this into account. Further, in any telephone system which is wisely planned there are elements which ought to last so long as to be overtaken by the time of which I speak. It is no fancy dream to expect such a condition. We will agree on this if we will stop to think of what has been accomplished by the Independent interests already. I am advised that there is under consideration the construction of a considerable length of long distance circuit of heavier copper than has ever been erected for any purpose of communication, and this by an Independent company. I can call to mind exchanges lying in the region of these excellent projected circuits from the stations of which I should be surprised to receive good speech even over lines of such cost and quality.

It may be that I have harped too much upon patience, persistence and common sense, and not enough on experience and preparation. It is true, of course, that these are necessary also. If there is one thing which has been of value in developing the telephone business, it is experience, and its application to the new things always arising. The successes that are to come will result from an intelligent use of what can be learned by a proper study of what has been done already.

EDITOR'S NOTE.—Paper read before the Convention of the National Independent Telephone Association of America at St. Louis.

CONSTITUTION OF THE NATIONAL INDEPENDENT TELEPHONE ASSOCIATION OF AMERICA

ARTICLE I.

The name of this Association shall be THE NATIONAL INDEPENDENT TELEPHONE ASSOCIATION OF AMERICA.

ARTICLE II.

The aim and purpose of this Association is to cement together in a firmer union all Independent telephone interests in the United States for the purpose of promoting uniformity of operation, maintenance and construction; to protect and defend the members of this Association by moral effort, co-operation and such other means as may be available; and any and all other purposes that are to the best interests of the members of the Association.

ARTICLE III.

OFFICERS OF THE ASSOCIATION. The officers of this Association shall consist of not less than 15 Trustees, one of whom shall be elected from each State having members or associations affiliated with this body; and as many more as may be necessary to give each State affiliated with this body one representative; a president, first and second vice-presidents, a secretary and a treasurer (which latter two offices may be filled by one and the same person).

The president shall be a member and ex-officio chairman of the trustees.

ARTICLE IV.

COMMITTEES. The president shall within 15 days after the annual meeting appoint an executive committee of 8 members, who, with himself, shall constitute a committee of 9 to be known as the executive committee of the association. The appointments made shall be approved by the two vice-presidents, treasurer and secretary, or a majority thereof and in case any appointment should not be so approved, the president shall appoint some one else agreeable to them to fill the place. The president shall also fill all vacancies in said committee within 30 days after they occur, subject to the approval of the foregoing officers.

ARTICLE V.

ELECTION OF OFFICERS. The officers herein provided for other than the executive committee shall be elected by ballot, upon the adoption of this constitution, and thereafter by ballot at the annual meeting each year, and shall serve until their successors are elected and qualified.

ARTICLE VI.

LITIGATION AND LEGISLATION AND OTHER COMMITTEE. There shall be appointed within 30 days after the annual meeting by the president, a committee composed of five members which shall be known as the committee on litigation and legislation, which shall have charge of all legislation affecting the interests of the association, and inquire into all litigation that might affect the interests of the association or its members. The chairman shall appont such other commttees as the association may from time to time direct; said committees to be approved by a majority of the other officers as heretofore provided.

ARTICLE VII.

ANNUAL AND SPECIAL MEETINGS. The annual meeting each year shall fix the time and place of the annual meeting for the following year and special meetings may be held at such other times and places, as the executive committee may from time to time direct. The call for any such special meetings shall set forth the subject or subjects to be considered at such special meetings and no business affecting the general interests of the association shall be disposed of except as specified in the call.

ARTICLE VIII.

MEMBERSHIP. Any State, district or local organization representing a majority in interest in such district of Independent telephone exchanges, or telephone toll lines in the United States with not less than 500 units, (each unit to consist of either one operating telephone or one mile of long distance toll line) and having subscribed to this constitution, shall be eligible to membership in this associaton upon an affirmatve two-third vote of the members present at any regular or called meeting of the association; provided, however, that application may be made in the interim between meetings to the executive committee who may pass upon such applications; and further provided, that the units represented by any such organization shall not be represented by any other organization in which they may have membership; and provided further, that after the State organization is completed in any State (or Territory), representing a majority of the Independent telephone or toll lines in such State (or Territory), district or local organizations in such States, shall not be eligible for separate membership in this association, except upon the recommendation of the State organization, or when after direct application to this association, that the reason for such direct application is valid and reasonable, whereupon they may be admitted by a two-thirds affirmative vote of the association and in no other way. Membership in this association, however, shall be contingent upon the payment of assessments levied as provided for in the following paragraph.

ARTICLE IX.

ANNUAL DUES. The annual dues shall be levied from time to time by the executive committee through the treasurer, who shall send out the call 30 days before the same is payable, which shall not exceed one cent per telephone or mile of toll line circuit per year.

ARTICLE X.

REPRESENTATION. The several State, district or local organizations being members of this association shall be represented at the annual or special meetings of this association, by delegates chosen or appointed by such State, district or local organizations, in such manner, as may be prescribed by the constitution and by-laws of such organizations, but the number of delegates so chosen shall not exceed 1 for each 10,000 units or majority fraction thereof, as prescribed in Article VIII hereof. The members shall be entitled to one vote for every 10,000 units or majority fraction thereof, local organizations having less than 10,000 units shall have such fractional vote as they represent.

ARTICLE XI.

QUORUM. A majority of all the delegates present at the annual meetings of this association, or special meetings thereof, duly called, shall constitute a quorum for the transaction of business.

ARTICLE XII.

DUTIES OF PRESIDENT. The president shall preside at all the meetings of the association, board of trustees and executive committee and shall approve and countersign all orders drawn on the treasurer thereof, and shall be the general executive officer of the association, for the purpose of carrying on the business of the association; and perform such other duties as may be prescribed by this constitution or the association.

ARTICLE XIII.

DUTIES OF VICE-PRESIDENTS. The duties of the vice-presidents shall be to act in their order in the absence of the president, and perform such duties as would devolve upon the president, if personally present. They shall act upon appointments made by the president as heretofore provided, and perform any other duties prescribed by the constitution of this association.

ARTICLE XIV.

DUTIES OF SECRETARY. The duties of the secretary shall be to keep the records of this association and notify all members of any general or special meetings of the same to be held; draw all orders upon the treasurer after approval by the president and auditing committee and perform such other duties as the executive committee may require.

Digitized by Google

ARTICLE XV.

DUTIES OF TREASURER. The duties of the treasurer shall be to collect all moneys from the members of the association and to safely keep and pay out the same upon the order of the president, duly approved by the auditing committee. He shall also be custodian of any contracts or other papers except the records of the proceeds of the association. He shall give bond of some approved surety company for such an amount as may be required by the executive committee; said bond to be approved by executive committee and paid for by the association.

ARTICLE XVI.

DUTIES OF TRUSTEES. The trustees may be called together at any time by the executive committee upon ten days' notice; the notice shall specify the object and necessity for calling the meeting. A majority shall constitute a quorum for the transaction of business. It shall be their duty to meet at the place of holding the annual convention, the day preceding the first session of the convention at 10 o'clock A. M. At that time they shall appoint a committee of three to audit the books and vouchers of the association and report their findings to the convention. They shall hear reports of the officers and executive committee, recommend a policy to be pursued by the association at their convention.

ARTICLE XVII.

DUTIES OF THE EXECUTIVE COMMITTEE. The duties of the executive committee shall be to co-operate with the officers in the promoting the interests of the association; they shall have the right to create the office of assistants to the secretary or treasurer and employ one or more persons to fill those offices, who shall give their entire time to the interests of the association. They shall appoint an auditing committee of three, whose duty it shall be to audit all bills of the association before payment is made. They shall fix salaries of all officers and employees; said salaries to cover actual time spent in the interests of the association. They shall be allowed actual traveling expenses when on the exclusive business of the association; they shall assist the officers in doing all things necessary to make the organization a success.

ARTICLE XVIII.

MEMBERS OR OFFICERS CEASING TO BE INDEPENDENT. Any member or officer becoming in any way connected with other telephone interests than those identified with the Independent Companies, shall be regarded by the executive committee as having tendered their resignation to said association. Any one becoming a member of or accepting an office in the association does so with the above understanding; and the executive committee shall in case of resignation of officers, appoint their successors until the next regular or special meeting of the association, when the vacancies shall be filled.

ARTICLE XIX.

COMMITTEES AT ANNUAL MEETING. The president shall appoint at the first session of the annual meeting, the following committees:

Committee on credentials.
Committee on nomination.
Committee on next convention.
Committee on amendements to constitution.

ARTICLE XX.

ORDER OF BUSINESS.

1. Meeting to be called to order by president.
2. The election of chairman.
3. Reading of the minutes of the last meeting by the secretary.
4. Report of officers and committees.
5. Appointment of committees, regular and special.
6. Program.
7. Hearing reports of committee.
8. Election of officers.
9. Transaction of miscellaneous business.
10. Presentation of new business.
11. Adjournment

ARTICLE XXI.

BY-LAWS. The executive committee may, in its discretion, adopt such by-laws as it may deem expedient, not inconsistent with this constitution.

ARTICLE XXII.

AMENDMENTS TO CONSTITUTION. This constitution may be amended at any annual meeting of the association by an affirmative vote of a majority of the members present; or at any special meeting of which due notice by mail shall have been given at least thirty days previously to every member of the association, when such notice shall specify among other things the sections of the constitution proposed to be amended and the amendments offered thereto.

REPORT OF CONVENTION OF MUNICIPAL ELECTRICIANS

THE ninth annual convention of the International Association of Municipal Electricians met this year at St. Louis, Mo., on Tuesday, Sept. 13. The meeting was called to order by President Farrand, of Atlantic City, N. J., at 9:30 A. M., in the Grand View Fraternal Hotel, who, in his annual address, congratulated the members on the fact that the meeting was to be held during the week of the Electrical Congress, when the exhibitors at the Exposition would be able to show them special courtesies. He also urged the members to special efforts to increase the membership of the Association, and in that way increase its field of usefulness.

Mr. Adam Bosch, of Newark, N. J., read a paper entitled "Limitations of the Telephone for Fire-Alarm Purposes," taking the position that the telephone should not be depended on as an alarm system, as it was more liable to mistakes than the regular automatic systems. The majority of the members took part in the discussion of the paper, agreeing with the writer.

Mr. W. H. Thompson, of Richmond, Va., wrote a paper on the "Inspection of Theaters from an Electrical Standpoint," but he was taken ill and unable to attend the meeting. His paper was read by the secretary.

Mr. Hatch read his paper, "Street Lighting."

"Methods of Testing" was the title of a paper prepared by Walter M. Petty, of Rutherford, N. J., and was given the best of attention by the members, and a general discussion followed.

The officers elected for the ensuing year resulted as follows: Walter M. Petty, Rutherford, N. J., president; J. B. Yeakle, Baltimore, Md., first vice-president; G. H. Holderman, Indianapolis, Ind., second vice-president; C. E. Diehl, Harrisburg, Pa., third vice-president; Charles Greenwald, New Brunswick, N. J., forth vice-president; Frank P. Foster, Corning, N. Y., Secretary; G. F. Macdonald, Ottawa, Canada, treasurer. Executive Committee—Jerry Murphy, Cleveland, O.; Wm. Crane, Erie, Pa.; M. J. Donohue, Niagara Falls, N. Y.; A. S. Hatch, Detroit, Mich.; C. L. Williams, Laurel, Miss. A. C. Farrand, Atlantic City, N. J.; W. H. Thompson, Richmond, Va.; F. C. Mason, Brooklyn, N. Y.; J. S. Craig, Toronto, Canada. Finance committee—W. H. Bradt, Troy, N. Y.; James Grant, New Haven, Conn.; T. C. O'Hearn, Cambridge, Mass., and J. D. Hall, Peoria, Ill.

In the selection of the place for the next meeting Erie, Pa., was the successful city.

On Thursday morning, Sept. 15, the association held a joint session with Section G of the Electrical Congress.

IN THE OPERATING FIELD.

NORTHEASTERN IOWA TELEPHONE ASSOCIATION.

THE fifth semi-annual meeting of the Northeastern Iowa Telephone Association was recently held in the parlors of the Gedney Hotel, Independence, Iowa. Twenty-five Independent telephone companies were represented. These comprise the entire membership of the association. The meeting was called to order by President Stevens, and the following program was carried out: "The Situation in Our Neck O' The Woods," O. F. Blazier, Rockford, Iowa. "Are Our Relations with Farmers Improving?" by A. H. McClun, West Liberty, Iowa. "Advantages of a More Compact Organization," by E. C. Hampton, Marion, Iowa. "Needed Legislation," by S. G. Elgin, Monticello, Iowa. "Long Distance Lines," by G. Houck, Belleview, Iowa. The session lasted two days, and the entire time was taken up with interesting discussions of the papers mentioned.

George F. Hewes, of the Sioux City Telephone Company, gave an address upon the subject, "The National Monopoly," which was one of the best speeches of the session. He also talked at length on the new automatic system, which is being installed at Sioux City. The regular business meeting of the association occurs each year in February, at which time the election of officers is held. The following is a list of the present officers: President, Victor H. Stevens; vice-president, J. F. Van Vors; secretary and treasurer, S. S. Lichty. The present standing of the association is in a first-class condition, and reports from the various companies intended to show that in general the past summer has been the most posperous in the history of the association.

L. D. LINES OF THE MARYLAND TELEPHONE COMPANY.

DURING the past few months the Maryland Telephone Company has extended its long-distance lines so that now they reach about 2500 cities and towns in Maryland, Delaware, Pennsylvania, Virginia, West Virginia and New Jersey. The subscribers to these lines number about 100,000. The company is completing the connection with Cumberland, Md., which makes possible communication with Pittsburg, Johnstown, Somerset, Erie and other towns in Western Pennsylvania and towns and cities in Western Ohio.

The company hopes soon to give service to Illinois through Independent companies operating in Ohio. The completion of the Cumberland connection, say the officials, will add 2000 cities and towns to the system, embracing about 120,000 additional subscribers.

MEETING OF DISTRICT NO. 4, OHIO INDEPENDENT TELEPHONE ASSOCIATION.

THE meeting of fourth district of Ohio Independent Telephone Association was held at Chillicothe, Ohio, August 30, 1904. This district comprises the counties of Pickaway, Fayette, Vinton, Jackson, Scioto, Lawrence, Pike, Adams, Highland, Clinton and Ross.

Mr. P. G. Thorpe, of Wilmington, vice-president of the Ohio Association, presided at the meeting, and E. E. Knox, of Portsmouth, O., acted as secretary. About twenty towns in the district were represented. Mr. F. L. Beam, of Columbus, president of Ohio Association, made a short talk on the ideas of the State Association.

Mr. J. B. Hoge, of Federal Telephone Company, Cleveland, spoke on general organization. Mr. C. Y. McVey, assistant general manager of Federal Telephone Company, Cleveland, made a few very good remarks on telephone service, and Mr. M. B. Overly, general manager United States Telephone Company, Cleveland, O., told of some of the developments of the long-distance company of Ohio.

The meeting was a very enthusiastic one and augured well for the success of the district organization.

Reports from each county in the district were made by members present, after which committees were appointed and the meeting adjourned, subject to call by the chairman.

ILLNESS OF JUDGE THOMAS.

JUDGE J. M. THOMAS, the former president of the National Telephone Association, is very ill at his home, Irvington-on-the Hudson, in New York State. His physician announces that there is no hope for Judge Thomas, and that at the most he can be expected to live only three or four months. As reported in last week's issue of THE AMERICAN TELEPHONE JOURNAL, the National Telephone Convention in session at St. Louis adopted resolutions of sympathy for its former chief officer, as follows:

ST. LOUIS, MO., SEPT. 23, 1904.

Be it resolved by the Independent Telephone Association of the United States, in convention assembled in St. Louis this 23d day of September, 1904, that it most earnestly deplores the illness of Hon. James M. Thomas, who is at his home in Irvington, N. Y.; that without detracting from the value of the services rendered the cause of Independent telephony by many others, it recognizes in Judge Thomas one who has done more for this cause than any other living man; that from his earnest, honest and unselfish labors in the general cause of Independent telephony, from its real inception until the time of his physical disability, he has not only accomplished a great deal himself, but has stimulated and encouraged others in the work, and to his efforts most largely is due the fact that in nine years there have been placed and are now in operation in the United States approximately two and one-half million Independent telephones.

Be it further resolved that we extend to him the sincerest sympathy of the members of the Independent Telephone Association, and through them for all others who are interested in this cause, and express the most earnest wish for his early and complete recovery.

Committee on Resolutions to Judge Thomas as follows: H. D. Critchfield, Chicago; Geo. W. Beers, Fort Wayne; Hugh Dougherty, Buffalo, Ind.; P. Sheeron, Indianapolis, Ind.; E. B. Fisher, Grand Rapids, Mich.; C. W. Kleine, Hazleton, Pa.; J. B. Hoge, Cleveland, Ohio; F. L. Beam, Columbus, Ohio.

SUB-MARINE SIGNALING FOR ST. LAWRENCE RIVER.

THE Canadian Government, by an order adopted in council at Ottawa, will enter into an agreement with the Submarine Signal Company of Boston for the installation of 30 bells in the St. Lawrence River and off the coast of the Maritime Provinces. Of the 30 stations to be established, 26 are to be operated from the shore and four from lightships.

It is expected that all ships making Canadian ports will be equipped with the telephonic apparatus for picking up the sounds of the bells. Already provisional arrangements have been made with the principal steamship companies of the Dominion for the installation of the apparatus.

The system has been installed experimentally for some months at Boston lightship, Pollock Rip Shoals lightship and Vineyard Sound lightship.

The telephone apparatus on the ships never fail to pick up the sounds of the bells at distances ranging from 4 to 10 miles. As there is no difficulty in locating the direction from which the sounds come, the mariner, by the use of the signal system, is

Digitized by Google

enabled to know his position when near a signal station, if he has wandered from his course for any reason, or if he is picking his way through a dangerous passage in fog or storm.

NEXT MEETING OF THE NATIONAL TELEPHONE ASSOCIATION.

JUDGE H. D. CRITCHFIELD, E. E. Clements and J. B. Hoge were appointed a committee at the recent National Telephone Convention to fix a time and place for the next convention. They are to report to the Executive Committee not later than three months before the proposed date, so that a general call may be issued.

CONVENTION DELEGATES RECEIVED SPECIAL ATTENTION.

AT the National Telephone Convention, held last week in St. Louis, the delegates were the recipients of special attentions from the various manufacturers that were very much appreciated.

After the adjournment of the convention the delegates were treated to a trolley ride, as guests of The Controller Company of America, on the private car "Mabel," belonging to Mr. E. G. Lewis, of the E. G. Lewis Publishing Company, who is secretary of the Controller Company. Mr. H. D. Stroud, engineer of that company, was in charge of the party. After a ride through the city the delegates alighted at the Mercantile Club, where an elaborate luncheon was served, after which the tour was continued.

The afternoon's entertainment was ended by an inspection of the now famous Woman's Magazine Building, which is owned by the E. G. Lewis Publishing Company.

Several manufacturers distributed souvenirs to the delegates at the convention. Among them were the Swedish-American Telephone Company, of Chicago, Ill., which presented the delegates with a small neat watch charm, telephone receiver of the same design as their standard receiver. This company also distributed leather blotter pads having an elaborate design and the name of the company stamped on the back.

The American Electric Telephone Company, of Chicago, had a unique souvenir in a small brass nickel plated telephone receiver, useful as a paper weight.

The Central Telephone and Electric Company, of St. Louis, furnished the delegates with buttons and convention badges.

The Kellogg Switchboard and Supply Company, of Chicago, had a very desirable souvenir in a purse whose combination lock caused some consternation and merriment.

INDEPENDENT SYSTEMS OF LEWIS COUNTY, MO.

IN Lewis County, Mo., there are two Independent telephone companies—the Lewis County Telephone Company and the Citizens' Telephone Company of North Missouri. The Bell company has hardly any telephones and these are at toll stations. Both the Independent companies operate in different territories, although in some towns both have exchanges. These systems are kept in first-class condition and the lines are all in good shape. There are country lines on almost every public road in the county, yet ten years ago there was not an exchange in the county and but few county lines. Both companies have cables across the Mississippi, that of the Lewis County system crossing at Quincy, Ill., and the Citizens' lines at Canton.

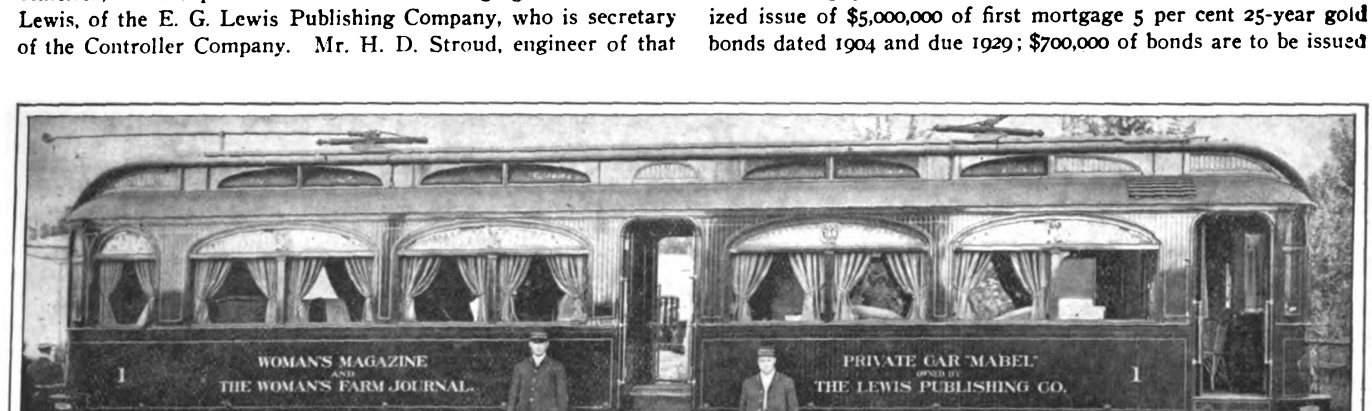
EXTENSIONS OF TOLL SYSTEMS OF KINLOCH L. D. TELEPHONE COMPANY.

THE following official statement has been issued by the Kinloch Long Distance Telephone Company, of St. Louis, Mo.:

This company has completed lines to Terre Haute, and established connection with the Indiana and Kentucky Independent long distance companies to Sedalia and Nevada, Mo., where connection is made with the lines of the Kansas City Independent Telephone Company, and has finished toll lines to Joplin. We have under construction now toll lines to Springfield, Ill., for connection with the Independent telephone companies operating in the northern part of the State of Illinois.

Our mortgage is dated January 1, 1904, and secures an authorized issue of $5,000,000 of first mortgage 5 per cent 25-year gold bonds dated 1904 and due 1929; $700,000 of bonds are to be issued on the present property and $300.000 whenever the company shall expend that sum for actual additions; the remaining $4,000,000 are to be issued from time to time when required by our company in amounts equal to 75 per cent. of the actual cost of permanent additions and improvements, provided the net earnings amount to at least the rate of 10 per cent. per annum on the principal of the bonds outstanding, and also the bonds to be issued at the respective times. The American Trust and Savings Bank, of Chicago, and Geo. W. Galbreath, of St. Louis, are the mortgage trustees.

None of the stock is owned by the Kinloch Telephone Co., nor are our bonds guaranteed by this latter company. Our stockholders, however, are in the main stockholders in the Kinloch Telephone Co. Of the $5,000,000 of authorized share capital, $400,000 has been issued.



Private Car Owned by Mr. E. G. Lewis, of the Controller Company of America.

CUYAHOGA SUES BELL.

THE Cuyahoga Telephone Co., of Cleveland, Ohio, has brought suit in common pleas court against the Cleveland Telephone Co. and Fred S. Avery, proprietor of the Euclid hotel. The hotel was equipped with the Cuyahoga company's telephones, and a few days ago the hotel management contracted to use the service of the Bell company. The latter, it is alleged, cut the wires of the Independent company and connected up its own. The contract is an important one as every room in the hotel is connected, a total of 200 telephones being used. The Cuyahoga company alleges that it went to great expense and is suing for the fulfilment of its contract with the hotel.

SOME REMARKS ABOUT THE TELEPHONE.

THE AMERICAN TELEPHONE JOURNAL, as the exponent of Independent telephony, of course, believes in the telephone and in the telephone habit—for it is a habit as well as a convenience. We would not for anything say a word against that most wonderful scientific contrivance. The telephone can speak for itself, and needs neither condemnation nor praise. But the fact remains that when it comes to service, in spite of its undeniable usefulness, the telephone, especially the Bell variety, is sometimes a nuisance. We mention this matter, not in a fault-finding spirit, but to emphasize the overshadowing importance of good service.

To be sure, the telephone facilitates business, to which somewhat doubtful blessing we all cry amen, as if business was the chief aim in life. But with the invention of the telephone our modern pandora has let an entirely new set of annoyances out of the box, which chasten the Christian spirit most severely. Undeniably the telephone is useful. But at what cost! Its way is strewn with ruined tempers and profanity. If thoughts, instead of spoken words, could be sent through the telephone, ordinary copper wire would be found entirely inadequate, were it three times as large. To sit down at the desk and hold conversation with some one in a distant city, or even in the next block, fills one with wonder and admiration. To talk into a hole in the wall and receive a more or less intelligent answer is enough to fill the soul with awe, when viewed in calmness and appreciation. But what if the telephone girl cuts us off in the most interesting part of the conversation? Ah, there's the rub, as Shakespeare would have said had he possessed modern advantages. It is all just as wonderful as before, but the spirit chafes at such interruption.

All of which shows what a queer creature the human mind is. A few months ago hours were required and expected as a matter of course for an answer to our question. A few years ago it took days to hear from a friend. We asked our questions and waited with unruffled temper for telegraph or post to bring us reply. Now, response must be instantaneous and uninterrupted, or there is trouble. It is useless to argue with human nature. When a person drops his work to answer the telephone bell and finds that the presence at the other end of the line has gone to sleep or has forgotten that he rang, does human nature stop to ruminate on the wonders of science? No. It promptly gets mad at the telephone girl. The aggrieved individual wants to call her up and tell her so frankly; but he cannot raise "central"; he cannot raise anybody. He sits down and becomes absorbed in his work once more. Then the bell sounds and the telephone girl sweetly inquires if he rang. In this evil manner does the aggravating invention follow him throughout the day, if the service is not all that it should be. These are little things, but it is the little things in life that grind human nature.

WHY GOOD SERVICE IS MOST ESSENTIAL.

He goes back to his toil and tries to forget that there is such a thing as a telephone; then the bell again sounds and a voice inquires if this is sixty-six. No! It is seventy-six! After a little, he asks for his grocer, and "central" gives him the coal dealer, with whom for certain reasons he dislikes to hold a conversation. He tries to get him off the wire and can't. He tries again. He jerks the instrument nearly out of place in vain attempt to get central. Each succeeding struggle brings the other fellow to the machine, until human nature can endure no more. Both he and the coal man gaze at the ceiling and heap dreadful maledictions on the innocent head of the telephone girl.

And so it continues until the tired victim of the telephone habit goes home at night to dream of telephone girls and the coal man.

Many and many a time in some small exchange, after wrestling with the telephone for hours until the burden became greater than he could bear, has the exasperated subscriber sought out the mysterious "central," going up the stairs two steps at a time, determined to cast the burden with great force at the feet of the telephone girl. But how the courage oozes when one stands face to face with a womanly presence! One can talk to a girl through miles of copper and express his mind freely. It is different at close range. Besides five minutes in a busy operating room will convince the most unreasoning that the telephone girl is more sinned against than sinning. Naturally, human nature is the same inside of a telephone room as outside, and no doubt occasionally an employee is found who is not courteous and vigilant, but it is safe to say that the telephone operators have more to try their temper and come in contact with a more varied assortment of human nature in the course of an hour than most people do in a week.

It is hardly necessary to more than allude to this question of service when Independent companies are concerned. From necessity, almost from the force of circumstances, Independents have been forced to lay unusual emphasis upon good service. In no other way have they been able to so successfully invade the field of the Bell monopoly. If for no other reason, the patrons of the many telephone companies owe a debt of gratitude to Independent telephony, for, by making good service its watchword, it has in many instances aroused its great rival out of its apathy and characteristic disregard for the rights and needs of the people.

The Telephone in the Courts

Conducted by A. H. McMillan.

Readers are invited to submit questions on any point of Telephone Law. They will be answered and explained on this page.

UNLAWFUL DISCRIMINATION

THE Southwestern Telegraph & Telephone Co. was sued by D. L. Phillips in the Circuit Court of Pulaski County, Ark., for unlawfully discriminating against him and refusing to supply him with telephone connection at his residence. Complainant sought to recover a penalty under the statutes of Arkansas, of $100 for each and every day that elapsed between his first demand and his last, the plaintiff alleging that he made a demand for connection continuously from day to day from July, 1899, until the middle of February, 1900. The defendant demurred on the grounds that the plaintiff did not state facts sufficient to contsitute a cause of action. The demurrer was sustained and the case carried to the Supreme Court.

Said the Court, "The plaintiff does not allege that he was discriminated against. Had he done so without stating facts constituting the discrimination, it would have amounted only to a conclusion of law, but he merely alleges that the defendant had refused and failed to supply him at his residence with telephone connection and facilities after repeated application by him therefor. Then he says, 'that by reason of the aforesaid discrimination and refusal, defendant has incurred a penalty under the provisions of the statute.' This does not amount to a statement of facts constituting discrimination. It is only a statement of facts constituting a refusal to furnish telephone connection and facilities, and we do not understand that this is actionable." The Court therefore sustained the judgment of the inferior Court in dismissing the complainant. Phillips vs. S. W. Telegraph & Telephone Co. (Ark.), 81 S. W., 605.

TELEPHONE LINES NOT AN ADDITIONAL SERVITUDE.

THE Supreme Court of Kansas has arrayed itself by a divided court with those States that hold the construction and maintenance of a telephone line upon a rural highway is not an additional servitude for which compensation must be made to the owner of the way over which the highway exists. In constructing a telephone line the Johnson County Telephone Company was proceeding to plant poles in a highway in front of the farm of Michael McCann. The poles were placed near the hedge fence on the line dividing the farm from the highway, and were so located as to interfere with the trimming of the hedge and also with the cutting of the grass and weeds on the roadside. He sued for an injunction, alleging that the company had not obtained his consent to plant telephone poles on the highway opposite his farm, that his interest as the owner of the fee had not been conveyed, condemned, or otherwise appropriated, and that no compensation had been paid to him for the proposed use.

In Kansas the adjoining owner of land owns the fee in a rural highway and retains the ownership of the land for all purposes not incompatible with its use as a public highway. The highway was established for the use of the public, and "the telephone line," the court held, is not only a public convenience, but is a recognized public use." "The question," said the court, "is, whether it is a contemplated and appropriate use of a highway, or a use outside the scope of a rural highway, and therefore, an additonal burden?" "The use of the highway," said the court, "has been variously defined to be for passage, travel, traffic, transportation, transmission and communication." The use is not to be measured by the means employed by our ancestors, nor by the conditions which existed when highways were first defined. The design of a highway is broad and elastic enough to include the newest and best facilities for travel and communication which the genius of man can invent and supply. In a certain sense, the telephone is an adjunct of the highway as a telegraph is of the railway. The messages transmitted over the line are a substitute for the messengers who formerly passed over the highway, and thus, to a great extent, relieved it from the burden and wear of travel. The court further held that the telephone was within the purpose contemplated when the highway was established, and refused the injunction asked for.

One of the justices expressed the opinion that the injuries complained of by the plaintiff were trivial. He said: "I am not in favor of opening the courts to injunction suits which are purely obstructive, which are brought merely for the vindication of a theory, and which have for their basis nothing more than an intangible interest in land which suffers nothing but an imaginary injury." Justice Johnson dissented from the views of the court, being of the opinion that a telephone *was* an additional servitude upon the highway. McCann vs. Johnson County Tel. Co., 76 Pac., 870.

COMPANY SUES TO PROTECT ITS EMPLOYEES.

THE Federal Telephone Company of Monongahela, Pa., has filed a bill of complaint asking that the Pittsburg & Charleroi Street Railway Company be compelled to raise its lines so that the lives of workmen may not be in jeopardy and the operation of its system may not be hindered. To support the statement that lives of men are in danger while working on the poles of the Federal Company, the bill mentions the electrocution of one of their employees last April, an accident which is claimed to have been caused by the proximity of the two lines, and not by contributory negligence. Over a portion of the distance from Black Diamond to River View the two lines run parallel, and it is the endeavor of the telephone company to have the street car company remove the high-tension lines to a safer place than at present. The bill asks that "the defendant be required to reconstruct said lines at points of interference as set forth in such a manner that danger and interference may be removed."

The street railway company in answer, claims that the high-tension lines carrying 15,000 volts are absolutely necessary to operate the road and that they were placed in position with full knowledge of the plaintiff company as to the voltage carried. The defendant company also alleges that at an extraordinary expense it obtained the tallest poles possible. The defendant avers that the death of the empolyee mentioned was caused by his own contributory negligence. The defendant avers that they are willing to make any concessions that are reasonable and proper, but consider it the duty of the plaintiff to move its lines.

COMPANY IN DEFAULT.

THE Missouri and Kansas Telephone Company will not be permitted to erect poles in the streets of Kansas City until it complies with the ordinance levying a tax on its poles and wires. The company has many applications on file for permits to erect poles and extend its wires. When these were brought up for action at a former meeting of the board of public works the subject was referred to the city counsellor to ascertain whether the company was complying with the city ordinance in the matter of erecting poles. The counsellor replied that the company was in default on its pole and wire tax.

The ordinance with which the company has failed to comply levies a tax of $1 a pole, twenty-five cents a mile on open wire and fifty cents a mile on wires inclosed in cables. The company contends that as it pays a tax of thirty cents a lineal yard on its conduits it should be exempt from tax on its poles and overhead wires. The city holds that the poles and the wires outside of the underground districts are subject to a tax.

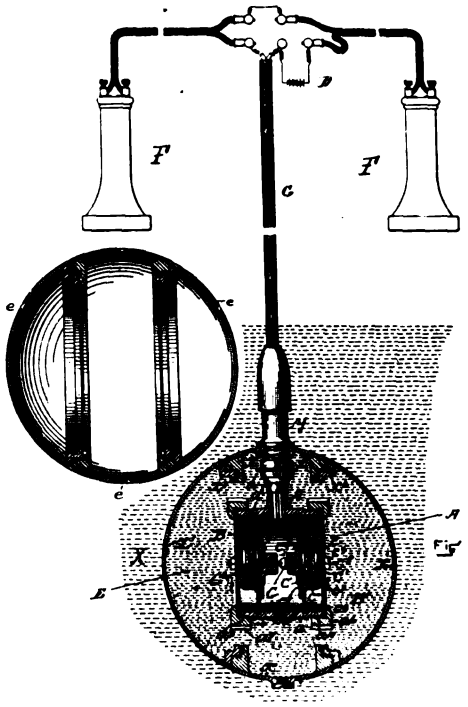
TELEPHONE PATENTS

SUBMARINE TELEPHONIC APPARATUS.

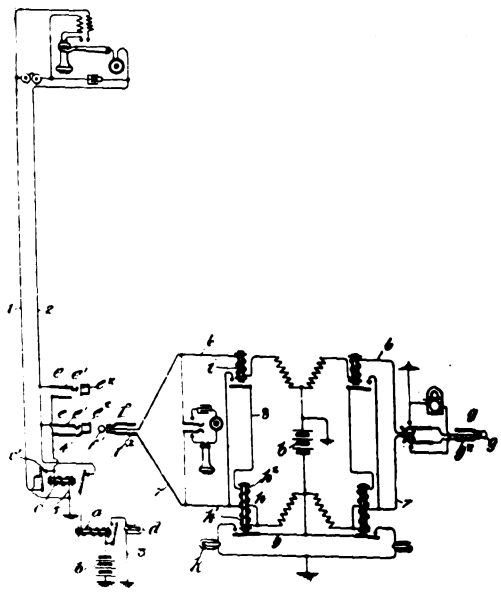
A. J. Mundy, of Boston, Mass., is granted patents (Nos. 768,568, 768,569, 768,570, 767,571, 768,572, 768,573 and 768,567) and assigns to the Submarine Signal Company, of Waterville, Me. The object of these patents relate to telephonic apparatus which is arranged to be submerged in water and to be used as detectors of sound waves which may be transmitted through the water. The essential features of the invention, which is protected by all of the patents, are shown in the accompanying illustrations, from which it will be perceived that the inventor provides a watertight cylindrical case, which is filled with a fluid capable of transmitting the sound waves which impinge upon its exterior to a microphone which is located in the center of the case. The micro-



phone consists of a fluid-tight box containing two diaphragms, as is shown, to which the microphonic buttons are attached, these microphonic buttons being connected with a pair of receivers through a waterproof cable. The theory of the invention lies upon the assumption that a sound wave traveling through the water will impinge upon the case, and will be taken up thereby and transmitted by the fluid to the diaphragms B and B', which will actuate the microphones attached to them and cause these sound waves to be repeated in the receivers, which may be located at any convenient place. The various patents cover the application of this device to ships, buoys and other similar cases where it is desirable to detect sound waves, which are transmitted through the ocean or long distances.

COMMON BATTERY CIRCUIT.

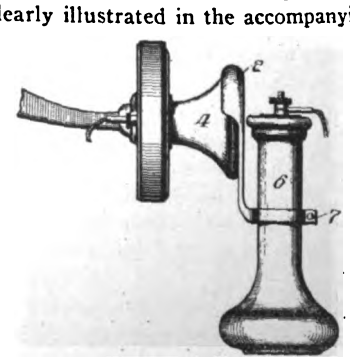
J. L. McQuarrie, of Chicago, Ill., patents (No. 768,617) and assigns to the Western Electric Company, of Chicago, a common battery circuit. The intention of this invention is to provide a two-wire circut which is adapted to common battery requirements, as is shown in the accompanying illustration. The operation of the system is as follows: When the subscriber removes the receiver, the line relay *a* is excited, closes the local circuit *3* and illumines the signal lamp *d*. The operator inserts the plug *f* into the answering jack. This completes circuit from the free pole of the grounded battery *b* through the strand *7* .contacts *f2* of the plug *f*, thimble *c2* of the spring jack *c*, conductors *4 5* of the cut-off relay *c* to the ground. The cut-off relay is excited and attracts its armature, extinguishing the line signal. The front contact *c'* of the cut-off relay is closed, completing circuit from line wire *1* to the free pole of battery *b*. A complete metallic circuit is now formed from the positive pole of battery *b* through strand *6*, tip *f'* of plug *f*, linespring *e'* of jack *e* to line wire *2* through the substation apparatus and back over conductor *1*, contact *c'* of cut-off relay *c*, conductor *4*, thimble *c2* of spring jack *c*, ring *f2* of plug *f*, con-



ductor *7* to the negative pole of battery *b*. As relay *i* is included in this circuit it is energized, closing branch *8*, including winding *h2* of relay *h*. The branch *5* forms the return path from conductor *7*, independent of the hookswitch, so that a local circuit is provided through winding *h'* of relay *h* so long as the cord is in use. Both windings *h'* and *h2* of relay *h* are now in the battery circuit, but these windings neutralize each other and the supervisory signal is not illumined. When the receiver is replaced the circuit through the winding of relay *i* is broken, opening branch *8* containing winding *h2*, then relay *h* becomes excited; its armature completes local circuit *9* and the supervisory signal *k* is illumined.

RECEIVER SUSPENSION.

W. Stanley Haddock, of Uniontown, Pa., patents (No. 769,863) an improved receiver suspension. This invention is intended to provide a new and novel method of suspending telephone receivers and is clearly illustrated in the accompanying figure, from



which it appears that the receiver is provided with a kind of hook clamp *7*, which is attached to the stem of the receiver, having its upper extremity so formed as to provide a hook which may be hung upon the mouthpiece of the transmitter.

THE TELEPHONE PATENT SITUATION

By Edward E. Clement.

THE subject of patents has probably been as closely considered by telephone men in the United States as any subject, even engineering practice bearing on their chosen work—and this for a very good reason. They have been forced to consider it or stay out of business. When the telephone was born, as usual there were several claimants for the honor of fraternity, and when the Supreme Court, by anything but a unanimous vote, confirmed the claim of Bell, it gave additional impetus to a fight that has raged ever since, and which bids fair to continue as long as men need to annihilate distance and use wires instead of legs. So when a man has come into the telephone business, he has needed some money, more sense, and a lot of nerve, together with a good knowledge of the patent situation or a competent adviser—and a man has had to be a fighter to succeed.

The reason some of the early manufacturers got their start so well was that in 1894 and 1895 the people at large were like a lot of sheep waiting to see which way they scented the wolf, and watching the dogs who wanted to lead them half in admiration and half in distrust. These men got a reputation as fighters and I occasionally get letters yet from back country districts up Northeast or out in the West recalling the fears and shakes of the old days ten years ago.

These very words, "old days," when we consider the brevity of the real time that has elapsed, tell a story. A giant has grown from a puny infant in that brief period; all the thirty or more suits brought by the Bell Company, and the thousands of patent claims outstanding, have proved only "Packthreads on Gulliver," powerless to hold him down. And the full promise of the giant's youth is not yet realized. All civilization rests on two factors—transportation and communication. The time will come when the electric telephone and the electric railway will encompass and cover this broad land, if not the world from ocean to ocean, and the telephone at least will cross the oceans. The present occasion furnishes a convenient opportunity to look backward as well as forward, to review past achievements, and to forecast from these what the future may hold.

We are met here for one purpose which all present, I believe, hope earnestly may be accomplished. I refer to the formation of a strong, representative and truly national association, which shall not only serve to unite and harmonize the operations of the various State organizations, but shall furnish an offensive and defensive alliance in the best and fullest sense. The necessity for such a body is strongly apparent, and its effect, not only in strengthening the market for telephone securities and insuring protection from patent persecution in the courts, but in adding to the facility and ease of transaction of business, cannot be overestimated. With regard to patents it is far too soon to consider the field as open. On the contrary, in this case, as in every other, eternal vigilance is the price of liberty. The old association has done excellent work in defending the suits brought under the Berliner and other patents, but its future work, if properly carried out, will be even more important.

Day by day more patents are being issued, month by month the Bell interests and Independents alike are acquiring new leases of monopoly on the application of principles which in the near future will become essential to the operation of high grade systems. The patent office is issuing an average of over thirty patents a month, and whereas a few years ago two examiners could handle the class of telephony, it now takes four, with the assistance of a fifth, and they are overworked. Few people have any adequate conception of what the patent situation has meant in work and money expended. I will give you a few figures to illustrate.

There have been issued 4,298 telephone patents, of which 3,798 are in the class of telephony proper, and 500 are scattered. I do not include in this number all the patents for electric lighting, power generation and distribution which have a bearing on telephone system as installed, but I should say there are probably 500 more of these.

The modern telephone plant is not essentially telephonic. It comprises really a power generating and distributing system, with auxiliary telegraph system, whereby the supply of power is controlled. The only thing telephonic about it are the transmitters and receivers at subscribers' stations and the central office.

Of the 3,798 strictly telephonic patents, that is, those so exhibited and classified, 3,798 are for receivers, 683 are for transmitters, of which 216 relate to the granular type, 469 relate to exchange systems and 715 to switchboards, of which 465 cover multiple boards exclusively, and the rest single or transfer boards. About 75 of the system patents also relate to multiple boards, and nearly 300 cover circuits which are applicable thereto. Ninety-five are to exclusively transfer systems, so the preponderance of choice in the favor of the multiple board is thoroughly apparent. Of intercommunicating or house systems there are 57 patented, and of party line systems 577. Of the latter, 200 employ step by step selective mechanism, and I believe there are two things every man who has an idle hour tries his hand at. They are car couplings and step by step telephone selectors. Both classes absolutely overworked.

There are 160 patents for transmitter arms and receiver supports, and 211 switch hooks. Last, but by no means least in importance at the present time, there are 125 patents for automatic exchange systems and apparatus. The actual number of automatic patents is small, but I assure you they must be measured by *weight* to be appreciated. No living man knows all the details of all the apparatus in those 125 patents, and no man ever will, not even the inventors themselves. Some of the devices are fearfully and wonderfully made, and some are distinctly abortions.

In these patents I estimate there are altogether 48,038 claims, each, of course, standing as a distinct patent for what it covers.

The patents have cost:

Government fees	$150,430
Attorney fees and expenses	200,000
Interferences	300,000
A total of	$650,430

This is what the patents themselves cost. It does not touch the value of the inventions, nor the amount at which they may have been capitalized, which has, of course, run into many millions. Nor does it touch the cost of litigation, past and present. For all this the people at large have to pay sooner or later. The manufacturer or operator is only a middle man, who collects on the one hand and distributes on the other. Out of the total number given, about 1,800 or 2,000 are owned or controlled by the Western Electric Company and the American Telephone & Telegraph Company (Bell).

Assuming that 20 per cent. of the patents in the class of telephony have expired, and that 30 per cent. are invalid or worthless, there remain 24,000 in force, many of which probably need serious consideration. A respectable percentage of these 24,000 belong to Independent companies or individuals, but I wish to point out that without more than a friendly understanding (which binds nobody), this is no guarantee that suits will not be brought on them. If the Independent companies, both operating and manufacturing, stand together, the Bell interests can never again do them serious damage by patent suits; and the growth of public sentiment in favor of Independent investments will be sure, though slow; but if any amount of litigation develops among the Independents themselves, it will be the very worst thing that could happen, and must have a very depressing effect. The weakness of a house divided against itself is proverbial, and so surely as the larger Independent companies are gathering the elements of

Digitized by Google

monopoly into their hands, so surely will division come. I know that men do not spend money in development and patents out of charity, nor do I mean to depreciate the full protection of every man's property; but surely there must be some division line between those things that are essential and those that are not. There are many patents on transmitters—683 in all—and the transmitter is a common necessity. Of the 216 granular instruments patented, probably 100 belong to Independent owners, and more are coming as fast as patent attorneys can hatch up new excuses for them.

There are 327 magneto receiver patents, of which probably 75 are modern and in Independent hands. Suits on such patents as these, where they cover only difference in details, should be discouraged. Of course, no one can be absolutely deprived of his right to go into court, but a strong restraining hand could tend to avoid scandals.

My suggestion upon this point would be that a national arbitration board be appointed, and that it be made absolutely obligatory upon all members of the association or its component State associations, as well as upon those non-members with whom they deal as purchasers, that they submit all disputes or questions of infringement to this board *before* going into court.

They need not disclose their proofs necessarily—but if a charge of infringement be made, the board should have an opportunity of passing upon the prima facies, so that if upon the face of things the complainant had not a righteous cause, he would go on with the official stigma attached to him stamped *Disapproved.* This board, of course, would have to be made up of disinterested men of sufficient standing and technical knowledge to give their decisions weight. I believe such an arrangement would tend to discourage litigations over trifles, and in my belief large causes of dispute are few and far between.

The manufacturers have shown a meritorious desire to avoid infringement of any patents, and some of them have spent large sums in securing competent advice to this end. This is money exceedingly well spent. Another method of achieving the same result would be to form a pool to hold all non-essential patents, with a scale of reciprocal royalties, so that any one in the pool could be free of the patents held for a reasonable sum per annum, which would be divided among the members in proportion to the pro rata royalties paid on claims they put in. This, however, is for the manufacturers to settle, although the operators are the parties most interested.

With regard to important suits of the past, or likely to be brought, especially by the Bell, in the future, the broadest patents are all expired, and the most threatening ones are out of business, temporarily or permanently. The Firman multiple board patent, the Haskins and Wilson busy test patent, the Seeley answering jack patent, and the Bell common battery patent are all gone forever, while Berliner is on the shelf along with the narrow subject matter to which he was restricted and which no one wants to use.

The Scribner patent, 330,061 (expired), was sustained against the switchboard, put in use at Mobile, Ala., but resulted in no other damage to the interests of the Independent telephone business. The Carty patent for the arrangement of bridging bells in party line work was sustained in the Millheim case, but was reversed in the Anthracite case and is now awaiting final decision by the Court of Appeals.

The suits brought by the Western Electric Company against the Citizens' Telephone Company, of Grand Rapids, Mich., on the Eldred patent, 303,714 (106 F. R. 215), and the Watson patent, 266,806 (89 F. R. 670), and against the Western Telephone Construction Company on patents 215,833 to Rosevelt (79 F. R.) and 270,522 to Watson (81 F. R. 572), and against the Williams Abbott Electric Company on the Gray patent 309,617 (108 F. R. 952), all resulted in defeat for the patents sued on and established the right of the public to use the various switching and switchboard devices alleged to have been covered by them.

More recently Judge Wing decided against the Western Electric Company on suits brought by it against one of the Independent manufacturing companies for the alleged infringement of four of its patents (357,358, 477,616, 488,033 and 552,729), involving the construction of spring jacks and annunciators, while suits on the five common battery patents to Bell 346,708 (expired), Stone 507,568, Scribner 559,616, Kitsee 430,960, and Hayes 474,323, brought by the American Bell Telephone Company against certain Independent operating companies, and suits brought by the Western Electric Company on patents 575,653, 488,938, 431,531 and 11,929 (reissue) against other Independent telephone companies have been indefinitely suspended awaiting the decision of the court in the alleged illegal purchase of the Kellogg Switchboard & Supply Company by the Bell interests. Numerous other patent suits have been brought and subsequently abandoned by the Bell interests, while suits on a number of patents, including 427,629, 669,708 and 667,463, in addition to those above mentioned, which have been indefinitely suspended, have not as yet received action from the courts.

Another decision has been rendered in Rochester within the past few days on a Bell patent, which will be welcomed generally. I refer to the Scribner patent 559,411, covering the control of supervisory lamp in the third conductor in the cord. The patent is declared invalid, I am informed, and this opens one more door which is of some importance.

On the whole, I can see no reason to fear successful attack along any important line from the Bell Company. I do not mean by this that there will be no suits, but they will be brought for effect only, and the effect can be discounted, if not entirely destroyed, by a united and harmonious stand. With the same amount of reasonable precaution and the same investigation that an investor in any other field would feel bound to make, every assurance can be given that success will continue to crown our banners in the future as it has in the past.

Independent telephone securities are absolutely safe, so far as patent suits now being prosecuted or to be brought in the future by the Bell people may go. All that is needed to create confidence is union, and I trust in closing I may be permitted to express my earnest hope, as one who has been with this movement since its birth, that its end will be more glorious than its beginning or in Oriental phrase, "May the end of this house be *Peace.*"

EDITOR'S NOTE.—Paper read before the Convention of the National Independent Telephone Association of America at St. Louis.

INDEPENDENT SYSTEM FOR CHICAGO SCHOOLS.

AN independent telephone system is to be established by the Board of Education of Chicago. It will connect all the public schools with the offices of the school board in *The Tribune* building. The object is to facilitate school work.

A subcommittee of the buildings and grounds committee, composed of Chairman O. A. Thorp, President Clayton Mark, and Trustee George J. Thompson will meet this afternoon to complete the plans. The cost of installing the service is estimated at $30,000, but the trustees believe it will be more economical to meet this initial expense and the cost of maintenance than to pay rentals to the Chicago Telephone Company for similar equipment. The manner in which the system is to be installed has not yet been determined upon.

The subcommittee has had the plan of establishing the Independent telephone system under consideration for more than a year.

ALASKA CABLE FINISHED.

THE last link in the government cable from Sitka, Alaska, and Seattle, Wash., was completed recently, when the cable steamer *Burnside* entered the Straits of Fuca and picked up the shore end for the final splice. This cable is solely for telegraphic purposes and was built by the United States Government to give a direct route without crossing foreign territory. It connects with Sitka, Skagway and Juneau, and will probably be extended to Dutch Harbor and Kiska Island, when a naval station has been established.

QUERIES

Questions on any subject relating to telephony will be answered on this page.

CROSS TALK AND TRANSPOSITIONS.—(429.)

Will you kindly inform me whether it is possible to transpose a metallic circuit so that there will be no cross talk or to reduce it to such an extent that it will be practical to use when run on same pole line for six miles with a grounded telephone circuit? If so, will you please state the best method of transposition for three grounded lines and one metallic circuit on a ten-pin cross arm for six miles? If it is possible to get rid of the cross talk on the metallic circuit, we could get along with the grounded lines. A. C. A.

Cross talk may arise from one or all of three causes. It may be due to electrostatic induction, to electromagnetic induction or to leakage. If the cross talk which you speak of is due to either or both of the first two causes, a sufficient number of transpositions will usually obviate the trouble, but if the cross talk be due to leakage, the best remedy is to improve the insulation of the several lines. We would suggest that you try the experiment of transposing your metallic lines in accordance with the accompanying diagrams. If you find that this is satisfactory, no further steps need to be taken. If after you make the transpositions the cross talk is decreased, but not sufficiently eliminated, it is probable that still further improvement can be secured by increasing the number of transpositions, say by doubling them. Whereas, if the experiment of transposing does not make a marked improvement, it is probable that the cross talk is due to leakage and it will then be necessary to improve the insulation of your lines.

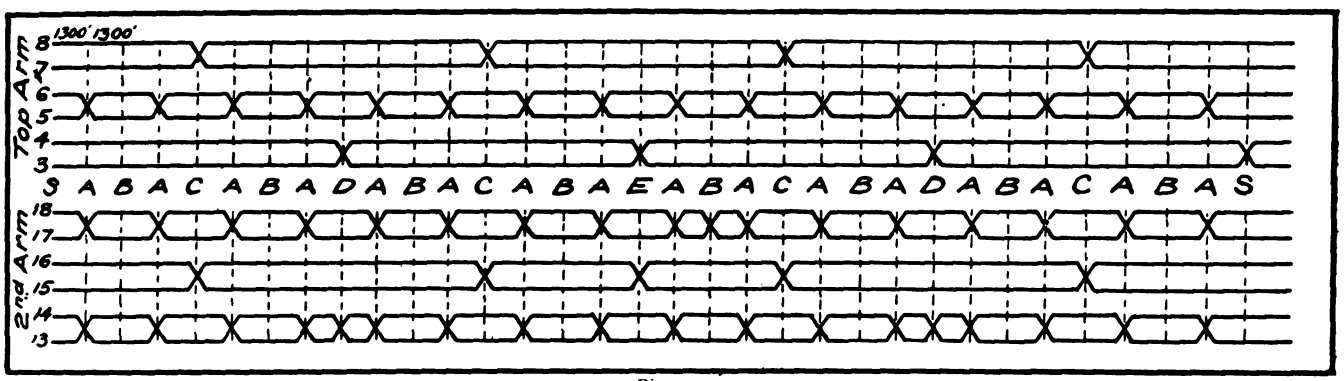

Fig. 429a.

BELLS AND CONDENSERS.—(430.)

We are considering changing over our system from magneto to common battery. At present we are using 1,000-ohm ringers; could they be used in the common battery instruments, and if so, what size condensers would have to be used? Could we use the old transmitters? L. Tel. Co.

We think it would be better to buy the common battery instrument complete, otherwise the telephones will be patched up and at best you will not save enough to warrant keeping the old ringers. If you have party lines of any size the ringers should have at least a resistance of 1,600 ohms. A 2 m. f. (micro-farad) condenser is the standard type used and will answer your purpose. The transmitters you have are of low resistance and intended only for local battery work. They would not operate successfully with common battery, and on this account it would be necessary to get common battery transmitters which are of much higher resistance.

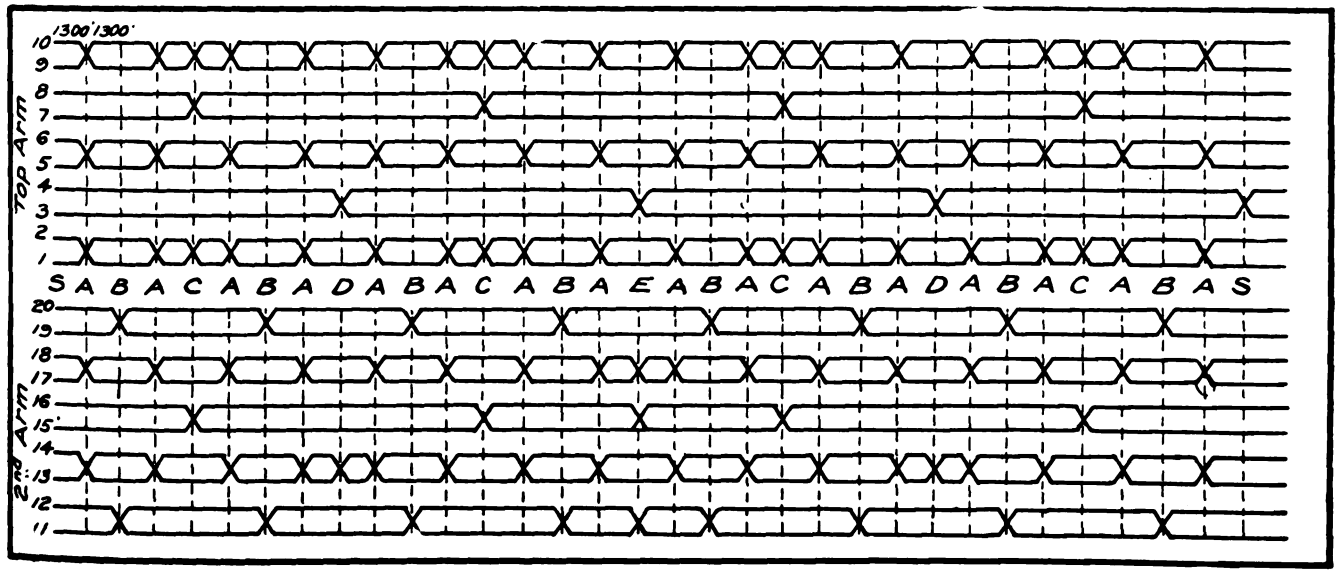

Fig. 429b.

CROSS TALK.—(431.)

We have bridging grounded lines and from 4 to 8 lines on a cross arm. The cross talk is bad. What is the best method of transposition to eliminate this trouble? G. C.

It is impossible to transpose grounded lines. The only way for you to overcome the difficulty with satisfaction is to make the lines metallic and then properly transpose them.

THE WEEK'S MESSAGES

FINANCIAL.

JEFFERSON CITY, MO.—The Kinloch Long Distance Telephone Company, of St. Louis, has increased its capital stock from $2,000,000 to $3,000,000 and will use the new capital to extend its lines.

ROUND LAKE, N. Y.—At a meeting of the Clifton Park Telephone Company a dividend of 8 per cent. was declared.

CLEVELAND, OHIO.—It is reported that the Cuyahoga Telephone Company will pay a dividend on its common stock after the first of January.

COLUMBUS, O.—The Citizens' Telephone Company, of Columbus, is now selling $300,000 of preferred 6 per cent. stock, the proceeds of which will be used for enlarging the capacity of the plant to 8,000 main line telephones and an ultimate capacity of 19,000 telephones.

PLATTSBURG, O.—The Plattsburg Home Telephone Company has increased its capital stock from $10,000 to $20,000.

ERIE, PA.—The Union Telephone & Telegraph Company will be reorganized with $500,000 capital, and the lines extended. About $30,000 worth of new copper has been added, and connections will be made with all principal cities.

SUSQUEHANNA, PA.—At the last meeting of the directors of the Centermoreland Telephone Company, held at Tunkhannock a few days ago, it was agreed to increase the capital stock of the company to $50,000. This increase is made necessary on account of the consolidation of this line and the Northern Tier and Factoryville companies. The business has grown to a business where several hundred miles of wire, four exchanges and over 300 telephones are required, in a little over two years.

LONE OAK, TEX.—The Citizens' Telephone Company, of Lone Oak, has increased its capital stock from $4,000 to $8,000.

FRANCHISES.

OCEAN PARK, CAL.—The trustees have granted a franchise to the Home Telephone Company to construct and operate a system here.

SONOMA, CAL.—L. Breitenbach has secured a franchise from the trustees of Sonoma for a telephone system.

BRANTFORD, ONT., CAN.—F. Dagger, representing the Starke Telephone & Electric Light Company, was here recently arranging the claims of his company for a local franchise.

COLORADO SPRINGS, COLO.—M. H. Spere will ask the City Council for a franchise.

CORDELLE, GA.—The Farmers' & Business Men's Telephone Company has been granted a franchise to do business here. J. C. Ledbetter is at the head of the company.

DODGE CITY, KAS.—An Independent telephone franchise has been granted to L. J. Pettijohn and others, as the city claims the present company is not living up to its contract.

YONKERS, N. Y.—The common council of this city extend an invitation to the State Line Telephone Company to apply for a franchise in the city of Yonkers, provided the company would agree to give better service and at more reasonable rates than is now being given by the Bell Company. The company has replied that it would be pleased to meet the members of the City Council to agree upon terms.

BELLAIRE, O.—The Ohio Valley Telephone Company has obtained a franchise to erect a system. Work will begin at once. Both overhead and underground wires will be used.

CLEVELAND, O.—Homer Hood, of Toledo, has asked the City Council for a franchise for the construction of an Independent telephone exchange.

TIPPECANOE CITY, O.—F. G. Davis, in behalf of the Home Telephone Company, of Troy, has asked the City Cuncil for a franchise to operate in this city.

PHILADELPHIA, PA.—The People's Rural Telephone Company has been granted a franchise through Glassboro Township, Gloucester County.

FAIRFAX, OKLA.—The Fairfax Telephone Company, which has just been incorporated with a capital stock of $10,000, has secured a franchise for an exchange at this point and will begin construction very soon.

WALHALLA, S. C.—George L. Wilson, general manager of the Oconee Telephone Company, of this place, has been granted a twenty-year franchise for a telephone system at Poll City, Ala. He will commence construction October 1st on a thoroughly up-to-date metallic circuit exchange. He has fifty subscribers in sight with rates at $2 and $3 per month for residences and business, respectively. He is in the market and desires quotations on all material necessary for the construction of this system.

PELL CITY, TENN.—George. L. Wilson has been granted a franchise and within a short time the line will be under construction. It will connect Pell City, Eastonville and Coal City.

NEW COMPANY NOTES.

MONTGOMERY, ALA.—The Enterprise Telephone Company has been incorporated with a capital of $15,000.

PETALUMA, CAL.—The Vallejo Township Telephone Company has been incrporated with a capital stock of $5,000 by J. Caltoft, W. Evart, G. W. Ormsby and others.

ASSUMPTION, ILL.—The Assumption Mutual Telephone Company has been incorporated with a capital stock of $5,000 by Allen Peabody, Seth Benepe and James A. Lambdin.

CHICAGO, ILL.—The Rogers Telephone Company, of Chicago, has been incorporated with a capital stock of $100,000 by G. L. Lavery, A. G. Welch and F. H. Sellers.

LAGRANGE, IND.—The People's Mutual Telephone Association, of Lagrange county, has been incorporated with a capital stock of $10,000. The incorporators are John W. Evans, H. D. Portner, M. C. Miller.

UNIONVILLE, IND.—The Unionville Telephone Company has been incorporated with a capital stock of $3,000 to construct and operate a local telephone system. The incorporators are George W. Welch, W. J. Slater, Milford Young, B. J. Linicomb.

LARRABEE, IOWA.—The Spring Cedar Mutual Telephone Company, with principal place of business at Grundy School House No. 6, Cedar township, Cherokee county, Iowa, postoffice address Larrabee, has been incorporated with a capital stock of $3,000. The officers are Richard Gilbert, president; H. I. Weaver, vice-president; A. D. Castor, secretary, and H. W. Braasch, treasurer.

WEST UNION, IA.—The Rogers Telephone Company has been organized here.

VIELE, IOWA.—The Viele Independent Telephone Company has been incorporated with a capital stock of $3,000. The officers are H. A. Skyles, president; Fred Auwaerter, vice-president; R. C. Coulee, secretary-treasurer; B. F. Drollinger, Louis Coulee and William Kudebeh, directors.

EL PASO, KAS.—The El Paso Telephone Company has been incorporated with a capital stock of $500.

GREENFIELD, KAS.—The Gove County Telephone Company has been incorporated here with a capital stock of $5,000.

NORTH BRANCH, KAS.—The Farmers' Mutual Telephone Company has been incorporated here with a capital stock of $4,400 to construct a rural line out of this city.

SPRING CREEK, KAS.—The Spring Creek Mutual Telephone Company has been incorporated with a capital stock of $5,000 to construct rural lines.

ORIOLE, MD.—The Manokin Telephone Company of Somerset County, with headquarters at Oriole, has been incorporated with a capital stock of $5,000 by Dr. R. J. Hoyt, Albert B. Fitzgerald, Isaac G. Parks, William L. Muir, George B. Dozman and Josiah P. Muir.

ZUMBRO FALLS, MINN.—The Zumbro Falls Farmers' Telephone Company has been incorporated with a capital stock of $7,000 by Frank Robinson, Bert W. Disney, Charles Anding, Albert Sugg, Albert Robertson, John C. Brinkman, James Ross and Jacob J. Springer.

BROWNING, MO.—The Browning Telephone Company has been incorporated with a capital stock of $1,070 by S. L. Gibson, F. M. Haymaker, M. R. Jenkins, J. J. Smith, E. B. Fields and others.

FAIRFAX, MO.—The Fairfax Telephone Company has been incorporated with a capital stock of $10,000 by J. A. Holt, M. C. Holt Eby and others.

LAMONTE, MO.—The Lamonte Telephone Company has been organized with a capital stock of $10,000 by J. A. Holt, M. C. Holt, Eby and others. president; J. A. Fleming, secretary; John McCurdy, treasurer.

ADAMS, NEB.—Adams is to have a telephone line in operation soon. F. B. Dasper is president and W. C. Gray secretary-treasurer.

JERSEY CITY, N. J.—The Dixon Home Telephone Company, with headquarters at 245 Washington street, Jersey City, has been incorporated with a capital stock of $125,000.

MADRID, N. Y.—The Madrid Telephone Company has been incorporated with a capital stock of $10,000 by E. M. Akins, Lisbon, N. Y.; G. P. Hosford and F. T. Rutherford, of Madrid, N. Y.

NEW YORK CITY, N. Y.—The Pinar del Rio Railway & Iron Company, of New York City, has been incorporated under the laws of Delaware with a capital stock of $1,000,000 of constructing telephone and telegraph lines and other purposes. The incorporators are Joseph Bailey, of Patchogue, L. I., N. Y.; Leonard L. Bishop, of West Hampden, N. Y.; Fred D. Gillin, of Chicago, and Louis G. Cone, of Havana, Cuba.

SMITHBORO, N. Y.—The Ross Hill-Smithboro Telephone Company has been organized at a meeting held in Ross Hill recently. The following officers were elected: Charles Carpenter, president; E. E. Bailey, vice-president; E. A. Hussong, secretary, and Charles Bedell, treasurer.

CLEVELAND, O.—The Telagirl System Company has been incorporated with a capital of $25,000 to operate an exchange for public and private stenography. Edwin C. Riegel, Oscar P. Riegel, Henry Wilker, Rud. C. Frey and M. E. Meisel are the incorporators.

DEFIANCE, O.—Highland township will have a Farmers' Telephone Association of its own. A company has been organized with twenty-two subscribers to start with and will have connection with twenty-eight switchboards of various farmers' associations. The company will make an effort to get its line into Defiance. The exchange of the new company will be located at Ayersville. The officers are: President, Henry Greenler; vice-president, John Baum; secretary, Will Stone; treasurer, John Stork. The above officers with David Hill, J. M. Myers and J. J. Thieroff compose the board of directors.

ELMIRA, ORE.—The Eugene, Elmira & Florence Telephone Company has been incorporated with a capital of $1,000 by J. L. Inman, F. C. Walters and others.

OPP, PA.—The Muncy Creek Telephone Company has been organized with the following officers: T. W. Raper, of Bardsville, president; W. S. Opp, of Opp, secretary, and P. W. Opp, of Opp, treasurer.

WILLIAMSPORT, PA.—The Buffalo Valley Telephone Company has been organized with a capital stock of $10,000. Hon. H. M. McClure, Hon. G. C. Mohn, Capt. William R. Follmer, Dr. James Kleckner, John P. Ruhl, Charles R. Ruhl and William Dreisbach, board of directors.

BATESBURG, S. C.—The Batesburg Telephone Company has been incorporated with a capital stock of $500 by William Westmoreland, of Samaria, president; Elijah Hall, vice-president; Dr. J. A. Watson, secretary and treasurer; E. F. Struther, attorney, and John Bell Towill, William Westmoreland, E. R. Steedman, J. F. Kneece and Wilson Gunter, directors. The company will construct a line from Batesburg to Steadman.

WALTERBORO, S. C.—The Colleton County Telephone Company has been incorporated by Dr. T. B. Whatley, W. T. Gray and C. C. Tracy. Work has already been begun on the local system, with connections to Centerville and Cottageville. It is the purpose of the company to give every part of the county connection with Walterboro and secure long distance connections.

NASHVILLE, TENN.—Secretary of State John W. Morton has granted articles of incorporation to the Tri-State Telephone Company of Shelby County with a capital stock of $10,000. The incorporators are Charles D. M. Greer, J. T. Warren, F. N. Fisher, L. T. Cavanaugh and A. Outsen.

HUBBARD CITY, TEX.—The Hubbard City Telephone Company has been incorporated with a capital stock of $5,000 by C. W. Hobson, A. L. Collins and Hyde MacFarlan.

JACKSONVILLE, TEX.—The Jacksonville Telephone Company has been incorporated with a capital stock of $15,000 by W. H. Sory, W. H. Sory, Jr., and M. L. Sory, of Jacksonville.

THORNTON, WASH.—The Interstate Telephone & Telegraph Company has filed articles of incorporation with a capital stock of $5,000. The officers are J. J. Stephens, president; Nelson Howard, treasurer, both of Thornton; Dr. T. A. Swain, of Pine City, secretary and general manager.

GRANTSBURG, WIS.—The Mutual Telephone Company of Grantsburg has been incorporated with a capital stock of $100,000 by Simon Thoreson, Anton M. Anderson and William R. Ahlstrom.

PEWAUKEE, WIS.—The Pewaukee & Sussex Telephone Company has been incorporated with a capital stock of $2,000 by A. T. Larson, S. L. McDowell and William Parker.

ELECTIONS.

BLAKELY, GA.—At a meeting of the Board of Directors the following officers were elected: Arthur G. Powell, president; Wade H. Powell, vice-president and general manager, and Kathleen Odum, secretary and treasurer. The company will soon have its line completed to Albany, when work will begin on the exchange at that place.

LAWRENCEVILLE, ILL.—The following officers have been elected by the Starr Line Telephone Company, which has been incorporated with a capital stock of $100,000: President, H. H. Knipe; vice-president, J. H. Senseman; secretary, G. W. Chamblin; treasurer, A. H. Calvin.

DECATUR, IND.—At a meeting of directors of the Citizens' Telephone Company the following officers were elected: Henry Hite, president; John Baker, vice-president, and E. X. Ehinger, treasurer.

NORTHVILLE, MICH.—At the annual meeting of the Northville Telephone Company all the old officers were re-elected. The company now has 186 telephones and twenty miles f lines in operation.

WEST MILTON, O.—The West Milton Home Telephone Company has elected the following officers: Dr. W. H. Kessler, president; Charles Ammon, vice-president; Havilah Coppick, treasurer, and C. E. Emerick, secretary and general manager.

COMBINATIONS.

MAROA, ILL.—The People's Telephone Company has sold its system to the Maroa Mutual Telephone Company, which was recently organized. The consideration was $13,500.

SIDELL, ILL.—The Sidell Telephone Company has purchased the plant of the Douglas Cunty Telephone Company at this place and Allerton.

STERLING, ILL.—The Farmers' Telephone Company of Lee County has bought the Lee County Telephone Company's system at Franklin Grove, Ashton, Amboy, Lee Center, Sublette and Walton.

CARROLLTON, MO.—The Carroll County Telephone Company has sold its exchange and line to the town of Tina and the rural lines running into Tina.

WAYNE, NEB.—F. B. Bell has sold the Wayne Telephone System to Arthur Overshiner, of Chicago. The line, however, will be managed by local people, the officers being A. J. Ferguson, president; A. N. Matheny, secretary and treasurer, and L. F. Heur, superintendent.

NASHVILLE, TENN.—The half interest in the Cullman, Ala., Telephone Company, owned by E. T. Gable, has been sold by him to S. L. Sherrill, of Hartselle, Ala., who owns the system at the latter place. The two companies will be consolidated and the entire system improved and extended. A line already in operation from Hartselle to Lacon will be carried into Cullman and give connection with those two points to Decatur and New Decatur. Walter Gable owns the other half of the Cullman company.

UNDERGROUND.

RIVERSIDE, CAL.—The Home Telephone Company is placing its wires underground.

HOUSTON, TEX.—The aldermen have instructed the city engineer to prepare specifications for the Citizens' Telephone Company for the immediate laying of 3,000 feet of underground conduits according to their franchise.

PERSONAL.

R. D. ADAMS has been appointed manager of the South Western Telegraph & Telephone Company's system at San Antonio.

O. F. ALLEN, of Temple, Tex., has been appointed manager of the local Exchange of the Southwestern Telephone & Telegraph Company.

A. C. BRANUM has been delegated by the Belmont Telephone Company to establish an exchange at Bethesda, W. Va.

R. O. BRUSH, of Middleport, N. Y., has been appointed manager for the Home Telephone Company's system at Batavia, N. Y., to succeed J. C. Burton, who takes charge of the sysem at Dunkirk.

F. W. BRIGGS, of the Chicago Telephone Supply Company, paid a visit to New York last week and left for home on Wednesday. He will make the trip in his touring automobile.

R. G. CRANE has been appointed manager of the Home Telephone Company's exchange a Long Beach, Cal., in place of J. D. Love, resigned.

F. J. PAYAK has opened an office at Room 234, Crossley Building, San Francisco, Cal., for telephone engineering and construction of Independent telephone systems.

F. L. VAN ALMEN has been appointed manager for the Fox River Valley Telephone Company at Appleton, Wis., in place of F. S. Green, who has resigned to go to Los Angeles.

MISCELLANEOUS.

SAN JOSE, CAL.—The Holmes Brothers are promoting a telephone system in the Rueker and Orchard districts in Santa Clara county.

DENVER, COLO.—The Denver Telephone Company has brought suit against the Colorado Telephone Company for $1,800,000 damages, which it alleges is due on account of the Colorado Telephone Company causing its franchise to be revoked.

CHICAGO, ILL.—The Burlington Railroad will operate its system of train dispatching by telephone.

TUSCOLA, ILL.—J. H. Robinson has sold the Tuscola Company's plant to J. S. Campbell.

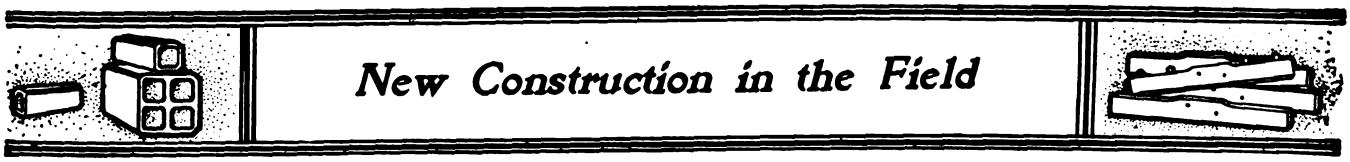
LAWRENCE, KAN.—The Lawrence Home Independent Telephone Company will install an automatic exchange.

ALEXANDRIA, O.—The new Independent exchange has secured 100 subscribers.

CLEVELAND, O.—It is reported that the Gould interests in New York are endeavoring to enter Cleveland.

NEWARK, O.—The Newark Telephone Company has increased its number of subscribers within the past few months frm 650 to 1,600.

KENOSHA, WIS.—A company has been formed here to take over and manufacture the telephone patents granted to W. E. Egan.



BLACK SPRINGS, ARK.—The Black Springs Telephone Company will commence work on the Cherry Hill and Oden line immediately.

JACKSONVILLE, ARK.—The Local Telephone Company has completed the line to Cabot and is now constructing a line to Lonoke.

SANTA MONICA, CAL.—The Home Telephone Company is rushing work on its long distance line. A franchise will be asked for in a short time.

WHITTIER, CAL.—J. T. Spencer, general manager and secretary of the Whittier Home Telephone Company, left here recently to visit Kansas City, St. Louis, Chicago and New York. While in Chicago Mr. Spencer will probably purchase material for reconstructing the local system. Gus. Wardman is acting manager at present.

MOLINE, ILL.—The Union Electric Telephone Company is arranging to construct a through metallic circuit connecting its local office with Taylor Ridge.

SPRINGFIELD, ILL.—New telephone cables are being laid between this city and Taylorville.

NEW ALBANY, IND.—The wire is being strung for a telephone line which will connect Corydon and De Pauw.

SOUTH BEND, IND.—A contract has been agreed upon with the Long Distance Telephone Company of Indianapolis which will give long distance service to Indianapolis. Direct connection may now be secured as far south as Kansas and St. Louis, Mo., and Louisville, Ky. All of the points in the southern part of Indiana may also be reached. A copper metallic circuit will be provided to Logansport from this city.

DES MOINES, IOWA.—The Mutual Telephone Company is planning extensions of its lines to Adelphi and Ivy.

READFIELD, ME.—The Crosby Telephone Company has purchased a larger switchboard and will move into larger quarters as soon as construction work is completed.

SOUTH CHINA, ME.—The China Telephone Company will begin work immediately. A. M. Fogg, of East Hebron, is in charge of the work.

OAKLAND, MD.—The Maryland Telephone Company is building a line from Baltimore to Romney, where it will connect with the Piedmont and Keyser company.

HOLLISTON, MASS.—The telephone company is constructing a new farmers' line.

MONROE, MICH.—The Stoddard Telephone Construction Company of Monroe has begun work on the construction of its new exchange. Direct connection with the Home Telephone Company of Toledo will be made.

NORWAY, MICH.—The Menominee Range Telephone Company is constructing a cable system in this town.

GLENCOE, MINN.—The Glencoe Telephone Company is enlarging its exchange and putting up rural lines in the surrounding country.

GOODHUE, MINN.—The Goodhue County Telephone Company is enlarging its telephone system, making many new improvements.

HECTOR, MINN.—The Hector Telephone Exchange Company has completed eighteen miles of rural line and is making improvements in its exchange.

TWO HARBORS, MINN.—E. J. Cooper, of Minneapolis, has been looking over the ground in Lake Superior with a view to building a telephone line between Two Harbors and Grand Marais.

WALDFN, MINN.—A telephone line is being organized at Walden and will run its line to Starbuck.

CLAYTON, MO.—Manager Houseman, of the St. Louis County Telephone Company, says the company will be in operation as far as Kirkwood within the next two months, and that the entire county system will be installed by spring.

PENTWATER, MICH.—The Lake Shore Telephone Company has about concluded work on the installation of its automatic telephone service in this town.

MONTEVIDEO, MINN.—The Montevideo Telephone Company has built eight new farmer lines this summer.

CANANDAIGUA, N. Y.—The new telephone line between Canandaigua and Rochester of the Interlake Telephone Company is rapidly nearing completion.

CLIFTON SPRINGS, N. Y.—The new telephone line which is being constructed to connect the villages of Clifton Springs and Newark is nearly completed.

HONEOYE, N. Y.—The Empire Telephone Company is erecting a new line. It is rumored that a number of farmers will ask that lines be extended to their residences.

Digitized by Google

TRADE NOTES.

THE S. H. COUCH COMPANY, of Boston, Mass., has filled a long-felt want in its Workwell Telephone. It is a thoroughly reliable set for short lines and can be used where any battery bell could be used. Bulletins free.

THE STERLING ELECTRIC COMPANY, of LaFayette, Ind., in addition to their pole boxes and outside terminals, have added to their line of manufacture an iron pole seat, which will meet with favor with construction people. The new telephone catalogue just being distributed by the Sterling Electric Company is a credit to that company and shows their advancement and progress in the instrument line by way of improvement and new designs.

THE BAIRD MANUFACTURING COMPANY, Chicago, reports a constantly increasing number of repeat orders for its pay stations, which indicates that Baird pay stations are a most profitable investment. During this month it has received an order for 300 additional pay stations from a telephone company in a large city which already has about 2,500 of these machines in service. The wideawake telephone manager will find that it will pay him to give the matter of pay station service very careful study.

A. N. MATTHEWS & BRO., 619 Carleton Building, St. Louis, have issued a second folder of a series which is devoted to droll descriptions of the worth of Stombaugh guy anchor. The durability of this anchor is entirely proved by Mr. Very Durable in an amusing manner. Among other witty remarks he refers to the Egyptian pyramids and the sphinx as evidence of the durability of the work done by his ancestors and claims that the use of Stombaugh guy anchor is as far ahead of other methods of guying as an Egyptian mummy is ahead of placing a dead man in a trench and covering it with earth. This folder will be mailed to all parties interested.

THE WILLIAMS TELEPHONE & SUPPLY COMPANY, Cleveland, O., has issued a new booklet entitled "Telephone Line Construction and Equipment." A good description is given of organization, together with a form for constitution and by-laws. Line construction is taken up and a general description given of the various materials which are necessary and the methods of construction to be used. Circuits are treated in a careful way and details are given of the various methods employed, together with diagrams. A brief outline of construction costs is given, together with a few reasons why the selection of "Williams" apparatus is one which will never be regretted. The company will be pleased to furnish this booklet and all information desired upon request.

THE CONTROLLER COMPANY OF AMERICA has recently secured a statement from E. H. Martin, of Waterloo, Iowa, that coin controlled telephones are bound to be adopted throughout Iowa; in other words, telephones that will not work unless a nickel is put in for each conversation. Mr. Martin is conceeded to be a very progressive and far-sighted telephone man, and his predictions are significant of the future development along this line, not alone in Iowa, but throughout the United States. At the same time as Mr. Martin's predictions, word is received from Mr. Higgins, of the Home Company at Los Angeles, a company that has done wonders in the way of progressive stunts, "that it has installed a large number of five-cent controllers over the city which are giving good satisfaction and proving a source of revenue, and that this service will be extended so as to cover territory where single lines will not pay."

THE MONARCH TELEPHONE MANUFACTURING COMPANY, of Chicago, has, after about eighteen months of careful study and experiment, produced a magneto switchboard, which it claims is the most up-to-date and practical board yet manufactured. The special tools required in making the drops and jacks, keys and other parts are almost finished, and the company can promise deliveries of complete boards within six weeks. A small folder, as a forerunner to a more complete catalogue, is now being printed and will give the reader an idea as to the mechanical construction of the various parts, as well as the method of assembly. Several new features are shown which it will pay any one interested in this class of apparatus to get further details of. Sample drops, etc., prices and full particulars will be sent to interested parties addressing the Monarch Telephone Manufacturing Company, 10-16 South Clinton street, Chicago, Ill.

FRANK B. COOK, of 238 West Lake street, has been meeting with the most flattering success with his No. 444 protector, which is equipped with self-soldering heat coils. This protector is manufactured under Mr. Cook's own exclusive patents, and it has been giving the best satisfaction to the many companies who have installed it. Some of the recent shipments of complete distributing frame equipped with a No. 444 protector have been those to the Pittsburg & Allegheny Telephone Company, for their Homestead exchange, a frame equipped for 600 lines, with an ultimate capacity of 700 lines. The United Telephone & Telegraph Company, of Pittsburg, a frame equipped for 100 lines, with an ultimate capacity of 200 for their exchange at Lewisburg, and a frame with a capacity of 100 lines for Norristown. The Milton & Milton Junction Telephone Company, a frame with a capacity of 100 lines for their exchange at Milton Junction, Wis.; the Yuma, of Yuma, Ariz., a frame equipped for 105 lines, with an ultimate capacity of 200 lines; the Sabine Valley Telephone Company, of Center, Tex., a frame equipped for 200 lines, with a capacity of 300 lines; the Kentucky & Indiana Telephone Company, of Owensboro, Ky., an ultimate capacity of 1,300 lines, equipped for 1,260; the Albemarle Telephone Company, of Charlottesville, Va., an ultimate capacity of 300 pair, equipped with 100 .

FOR SALE

Advertisements under this head, $1.00 for 25 words or less for each insertion. Prepaid.

FOR SALE CHEAP—Sixty series and bridging magneto Telephones recently taken out of service on account of change of equipment to central energy. Will sell in lots of two or more. Write for particulars. M. R. TRACEY, 231 Huron street, Toledo, O. 251

American Telephone Practice

By KEMPSTER B. MILLER, M. E.

518 large pages, profusely illustrated with 380 diagrams and cuts of apparatus **$3.00**

A book for the telephone man. It is an encyclopedia of useful information concerning telephony.

It gives complete specifications, enabling you to intelligently order apparatus from manufacturers, and to properly supervise the installation of an exchange, large or small.

It describes in simple language the theory and practice of modern telephony, including circuits, mechanical construction and operation of telephones and switchboards.

A complete description is given of storage batteries, their care and maintenance; of aerial and underground line construction, and, in fact, all the important matters which telephone men need to know.

Bituminized Fiber Conduit
For Underground Construction

Combines the **good features** of other conduits. **Eliminates** the **bad features** existing in many kinds. **Has valuable features** not found in any other ducts. :: ::
Made in 7-foot lengths with male and female joints, making construction very rapid and simple, with consequent low cost. :: :: ::
Alignment is perfect and permanent without tedious care and skill required in laying of butt-joint conduits. Users are astonished by the ease and rapidity with which cables can be drawn in, and this without the slightest scratching or injury to the lead covering thereof. Made in sizes from 1-inch to 10-inch diameter. ::
Bends of any radius and any angle. :: ::
Write us for further information and prices, stating sizes and quantities required. :: :: ::

THE USE OF THE TELEPHONE IN RAILROAD OPERATING

By Elmer Stone.

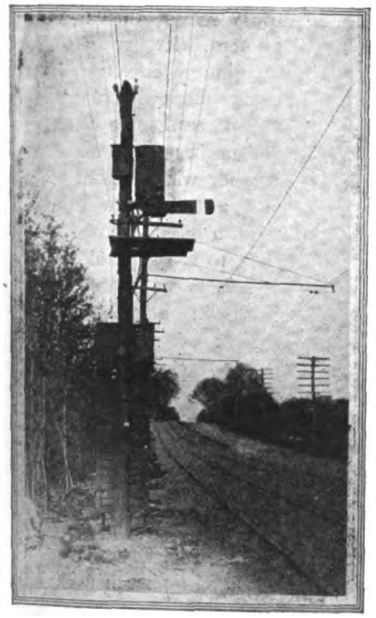

Fig. 1. Semaphore Set at Stop.

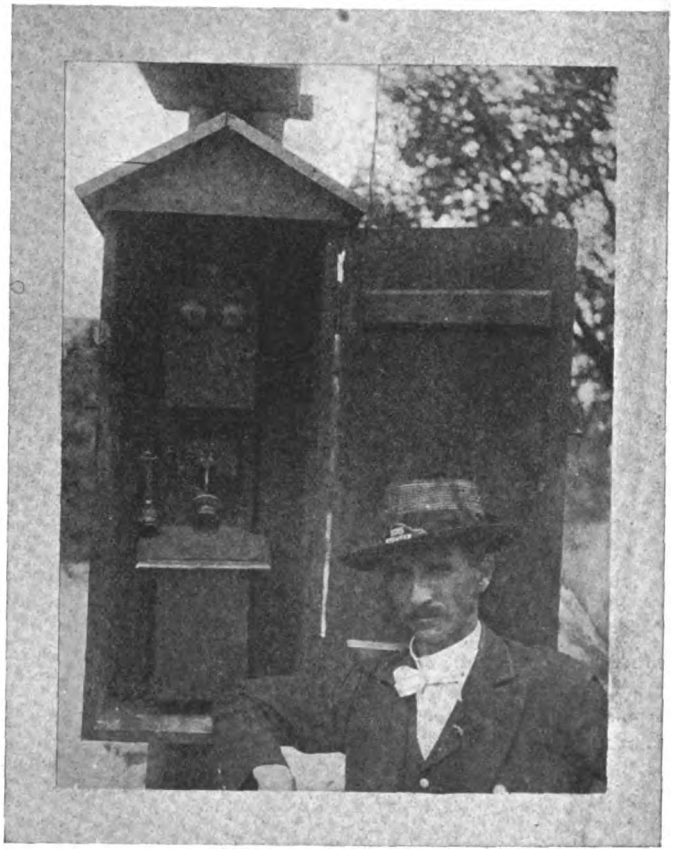

Fig. 2. Street Railway Telephone in Newark, N. J.

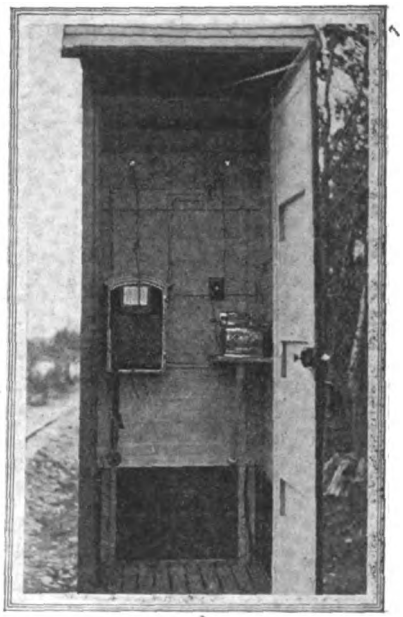

Fig. 3. Interior of Signal Station.

THE use of the telephone in conjunction with the operation of electric railroads is becoming more general every day, and a number of steam railroads are equipping parts, if not of all their systems, with telephones. In fact, in some instances the dispatching of trains is being done by telephone, thus supplanting the use of the telegraph.

The Illinois Central Railroad has operated a telephone system for quite some time over sections of its road, and recently decided to make numerous extensions with a view to long-distance service. The New York Central Railroad, as well as the Erie, are building long-distance lines between their termini in New York and Chicago, and the Pennsylvania lines have telephone systems in operation at all important points. The Chicago, Burlington and Quincy Railroad, after a number of experiments, has decided to use the telephone in train dispatching and it is certain that within a short while the use of the telegraph will be only auxiliary to if not entirely supplanted by telephonic communication.

The application of telephony to railway work involves features which are entirely foreign to its general application and which have heretofore caused a disinclination upon the part of railway operators to use it any more than as a local auxiliary to the yards or train sheds.

The principal objection has been the lack of permanency in the matter of records. With the telegraph the act of recording the message is a check upon the sending and receiving operators, but with the telephone there was no means of proving the correctness of a transmitted message. Another feature which formed a considerable drawback was the uncertainty of correct transmission; that is, would the receiving station receive the message exactly as it was transmitted?

It is a well-known fact that with the earlier types of transmitters and receivers it was almost impossible to distinguish between certain similar sounds. The writer is acquainted with an instance where a telephone system was installed in a large restaurant for the purpose of sending orders to the kitchen. Special care was taken in the design of the transmitters and circuits that the transmission should be as perfect as possible. After the system was completed everything worked to perfection. The enunciation of all the words that were used seemed perfect and all parties were congratulating themselves upon the system's success when an order calling for Swiss cheese was made and the receiving end interpreted it as split peas. All sorts of tests were made to get over this difficulty, but it proved the Waterloo of the system, and it was discarded shortly after. One can readily understand that in train dispatching there must be some means whereby a check can be placed upon a system and also that the apparatus must be as nearly perfect as possible.

The rapid increase in the use of electric railways for inter-

Digitized by Google

urban service and their invasion of the field of steam roads for distances of forty or fifty miles, or even greater, has accentuated the necessity for essentially the same methods of operation for electric as has proven best in steam road practice, including the use of regular train or car dispatchers; simultaneously there has arisen the question of communication between dispatchers and car crews, so that in the event of any unforeseen derangement of traffic or advisable change in operation, the dispatcher could communicate with his various train crews and change his orders to meet the new conditions. The relative necessity for thus communicating with crews cannot be measured by the track mileage for the reason that for a given number of miles of track the electric road will operate at least three or four times as many train units as the steam road under ordinary conditions, while on special days and holidays the electric road traffic will increase in a much greater proportion.

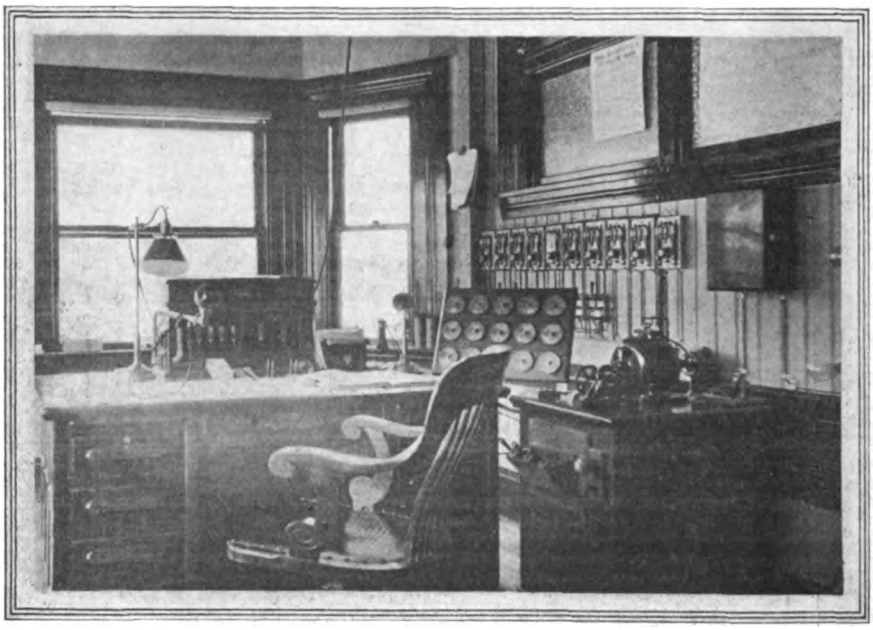

Fig. 4. Dispatcher's Office.

In winter, when snow plows and sweepers must be sent over the lines the need for this power of communication likewise becomes acute to a greater extent on the electric road.

Realizing this fact, the management of many electric roads installed telephones at certain points. An illustration of one method is shown in Fig. 2. This station is on a short line and is used by the inspector to communicate with the car stables in emergency cases. In other instances stations have been placed at different points along the track, either in the shape of waterproof telephone boxes or else a telephone is carried on the car and connection made by means of a pole which hooks over the telephone lines, or else a jack box is mounted on a pole and a flexible cord used.

With these methods the problem, so far as allowing the car crew to communicate with the dispatcher, or starter, as he is sometimes called, is solved, but the more important matter of permitting the dispatcher or starter to selectively communicate with the car crews is not. To accomplish this, in many cases, orders are given that at certain points all car crews should stop and call up the dispatcher, or the dispatcher might display signals or ring bells at all telephone points and, after stopping all traffic for a few minutes, select the crew desired and give his orders.

It will be evident to the reader that methods such as these leave much to be desired not only in the amount of time that might be saved, but also that the very effect desired, namely, the operation of a system upon a schedule, is lost through the delay to the different train units.

To further realize the truth of this argument, let anyone imagine every train being stopped on a steam road, for instance, because a dispatcher wished to direct a train crew to take a certain cross over to run around a wrecked or disabled train in a double-track road, or if on a single-track to notify a train to advance ten or fifteen miles rather than wait for the passing of another train that was considerably behind its schedule.

Since the telephone has reached a state of perfection that makes it as safe and reliable as any human agency can be, its use has become so general that everyone who is accustomed to it can use it with facility. It is an ideal method of communication, provided no specially trained operator is needed to handle it, and that there is some method used in conjunction with it to verify reports.

The one point that has been lacking to prevent its general use in railroad operating is some means of signaling that is simple in mechanism, positive in action and reliable in service that can be operated by the dispatcher so as to call to a telephone at any desired point, and *at that point only,* any one of the crews on the line.

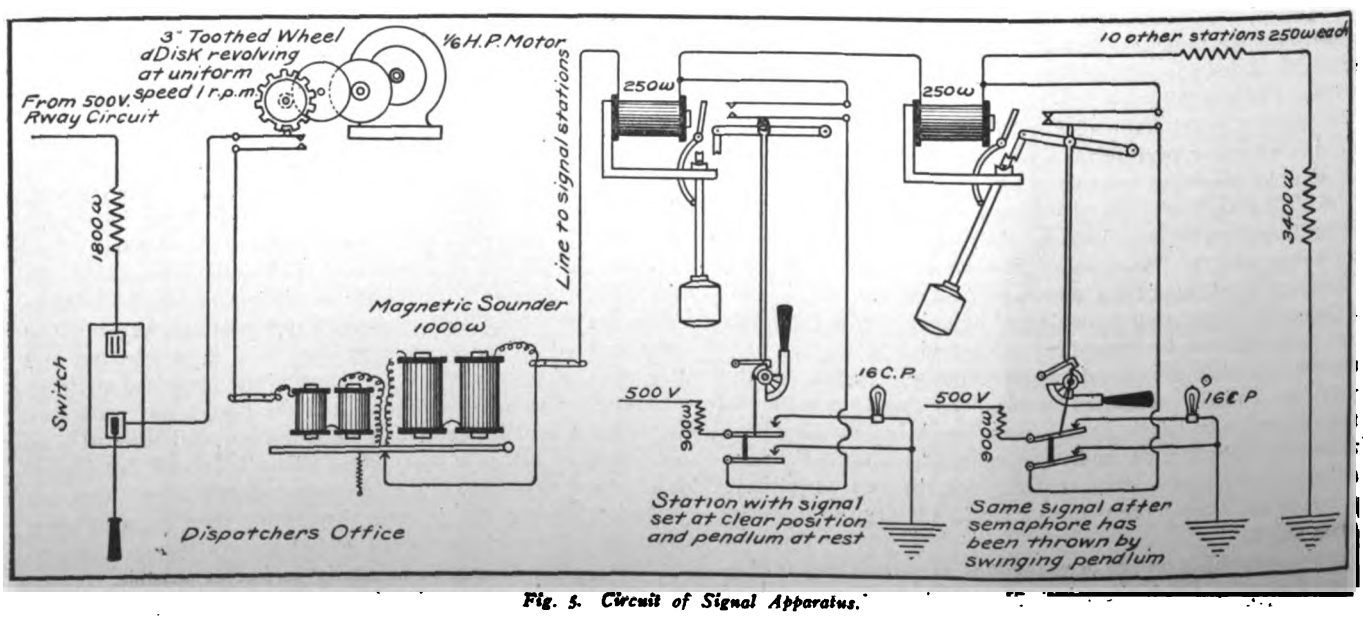

Fig. 5. Circuit of Signal Apparatus.

Digitized by Google

A system designed by the Blake Signal Company to meet these requirements has been in operation on the Boston & Worcester St. Ry. Co. for a period of five months, during a winter of exceptional severity, involving the severe tests of extreme cold and quantities of snow, ice, sleet, etc.

Over the entire line a first-class telephone system was installed and at all important operating points or turn-outs a signal has been placed. All telephone signal stations are furnished with an autographic register, which renders in triplicate the orders received at the station. The method of operation employed in this instance is as follows: Suppose the dispatcher wishes to communicate with a car crew approaching station No. 9. He picks up a three-inch toothed disk, numbered to correspond with the signal which he wishes to set, and slips it on a constant speed motor driven shaft located directly at hand. This throws a four-foot semaphore to a "stop" position at the station required, at the same time illuminating a red lens for a night signal.

As soon as the semaphore is properly set at "stop" the dispatcher is automatically notified of this fact by the operation of a magnetic sounder in his office. When the car arrives at the station, the conductor unlocks the booth and calls the dispatcher by telephone, saying, "Brown & Hayes at No. 9 for orders." The dispatcher then transmits his orders to the conductor, who writes them on the autographic register, repeats them back to the dispatcher, takes one written copy for himself, hands one to his motorman and the third copy is wound on a roll within the register where it is accessible only to the management. The conductor then pulls a cord which sets the semaphore at "clear" position ready for future operation. Figure 6 shows the semaphore set at "clear," Figure 1 at "stop" position and Figure 3 shows interior of booth with telephone on left, autographic register on right and cord suspended over telephone for resetting of signal. Figure 4 shows interior of dispatcher's office and Figure 5 shows a circuit of the apparatus.

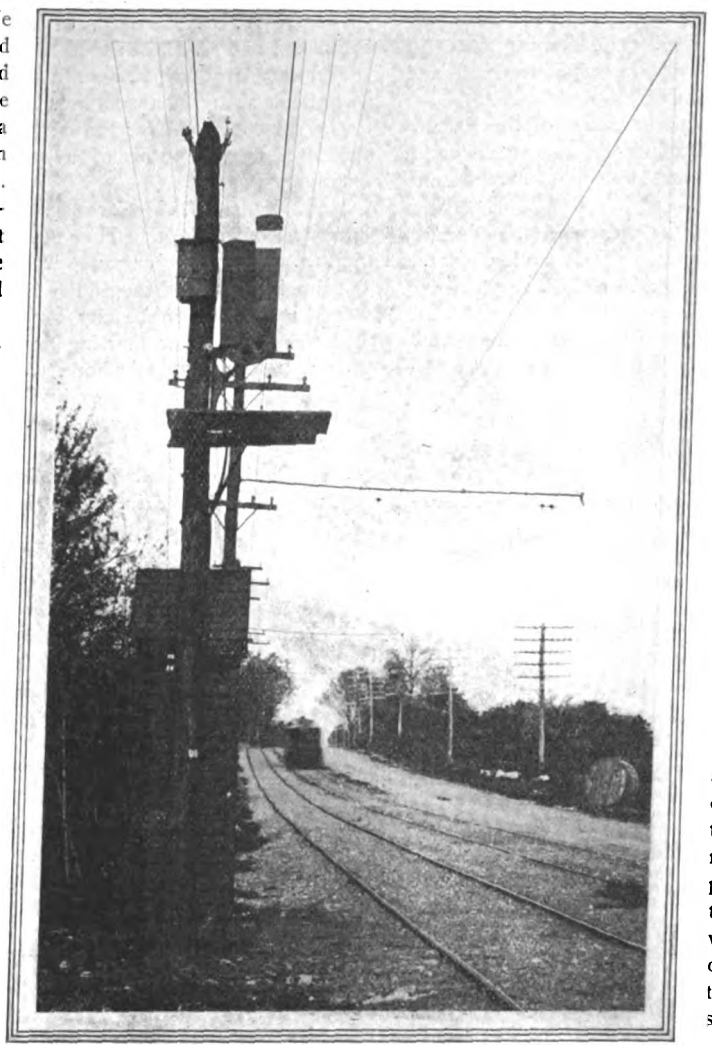

Fig. 6. Semaphore Set at Clear.

In designing the mechanism to operate the signal one of the principles of elementary mechanics was employed. Briefly stated, it is this—*the period or time of vibration of a pendulum of certain length is always the same.* Each signal box upon the line contains an electromagnet and a pendulum. The electromagnets are all in series on a single wire, a ground return being used preferably, although in case of need a metallic circuit could be employed. The pendulums for each of the signals are of different lengths and respond only to impulses from the electromagnets, which may be energized at various intervals corresponding with their respective periodicity of vibration.

It may be interesting to note in passing that a principle involving similar laws was employed by W. W. Dean in devising a selective ringing system. In operation the dispatcher, either by the use of a constant speed shaft on which he places toothed wheels for making and breaking contacts at various intervals corresponding with the periods of the various pendulums, or by means of setting in motion a pendulum corresponding in length and consequently synchronous with the pendulum of the signal which he desires to set, causes electrical impulses to be sent over the line at certain intervals which affect all of the electromagnets. These impulses are felt by all the pendulums, but are only cumulative in increasing the arc of vibration of that pendulum whose period is synchronous with the predetermined period of electromagnetic impulses. After from ten to twenty seconds, depending upon the length of the pendulum, it swings through an arc of sufficient length to enable it to trip the lock holding the semaphore in a vertical or "clear" position, and the semaphore at once falls to the horizontal or "stop" position.

When the semaphore has reached the horizontal position it automatically closes a lamp switch which gives the illuminated signal needed for use at night. Each signal is equipped with two incandescent lamps, so that, in the event of one lamp being burned out when the semaphore is set at "stop," the other lamp is automatically connected to a periodically interrupted circuit and gives a flashing danger signal. When in a horizontal position the semaphore also automatically closes a circuit which gives a magnetic sounder signal to the dispatcher, notifying him that the signal has been set as desired.

To ensure a constant speed with the widely varying voltages of electric railway circuits a governor is placed on the motor shaft. Another method which is also employed in place of a motor is the use of a master pendulum which removes the necessity of using current to operate the motor and is, besides, absolutely positive in action.

With some modifications a system similar to this could be applied to steam roads, especially on single-track branch lines where traffic is insufficient to warrant the expense of maintaining a force of telegraph operators. In such service, since there would probably be no electric current available for operating the motor in the dispatcher's office and the signal lamps on the line, the master pendulum could be used in the first case and batteries at each signal for the lamps.

The amount of current used in energizing the electromagnets and operating the signals is eight-hundredths (.08) of an ampere with a voltage of 650, equivalent to 52 watts, for the few seconds necessary to operate the signal, or an average of about .000217 k.-w. hr. for each time a signal is set. A one-sixth horsepower motor is sufficient for revolving the toothed disks in the dispatcher's office, and is in operation only while signal is being set. The signal should be installed preferably entirely independent of the telephone, a single No. 10 galvanized iron wire with ground return being sufficient for line connections.

In this way the cost of installation can be made as low as possible compared with other methods of railroad communication.

REPORT OF PENNSYLVANIA STATE INDEPENDENT TELEPHONE ASSOCIATION CONVENTION

(By our Special Correspondent, W. G. Newbold.)

THE annual convention of the Independent Telephone Association of Pennsylvania was held at Harrisburg on September 27th and 28th. This convention was in many ways a surprise to the people of the State, who had only in a general way realized the importance of the Independent movement and its benefits to the subscribers. The evening issues of the newspapers displayed a large amount of enthusiasm and carried the story of the proceedings with display heads.

H. E. Bradley, of Philadelphia, superintendent of the Eastern Traffic Association, arrived in Harrisburg on the afternoon of the 26th and established headquarters at the Commonwealth Hotel.

The first step toward active business was taken on Tuesday morning, when the executive committee met. Following this came a meeting of all of the delegates at 8 o'clock that evening, when the permanent organization was effected.

The city in which the convention was held was honored by the body electing as its president Benjamin F. Meyers, of Harrisburg. Mr. Meyers is president of the Cumberland Valley Telephone Company, and one of its largest stockholders.

Other officers were elected as follows: First vice-president, R. E. Flinn, Pittsburg; second vice-president, Charles Griffith, Johnstown; secretary, H. E. Bradley, Philadelphia; treasurer, C. E. Wilson, Philadelphia.

The following executive committee was elected: B. F. Meyers, Harrisburg; C. W. Kline, Hazleton; C. E. Wilson, Philadelphia; J. G. Splane, Pittsburg; R. E. Umbel, Uniontown; W. D. Barnard, Philadelphia; E. D. Schade, Johnstown; William B. Trask, Erie, and G. B. Rudy, York.

The members of the old executive committee, responsible for the calling for the convention which resulted in the Pennsylvania State Independent Telephone Association, were:

C. E. Wilson, of Philadelphia, general manager of the Keystone Telephone Company and president of the Keystone State Telephone Company; J. G. Splane, of Pittsburg, president of the Pittsburg and Allegheny Telephone Company; Hon. R. E. Umbel, of Uniontown, president of the Maryland, Pennsylvania and West Virginia Telephone and Telegraph Company; W. D. Barnard, vice-president of the United Telephone and Telegraph Company; E. D. Schade, of Johnstown, secretary of the Johnstown Telephone Company; Senator C. W. Kline, of Hazleton, president of the Consolidated Telephone Company, of Pennsylvania; William B. Trask, of Erie, president of the Mutual Telephone Company, of Erie; George B. Rudy, of York, general manager of the York Telephone Company; H. E. Bradley, of Philadelphia, superintendent of the Eastern Traffic Association, and Hon. B. F. Meyers, of Harrisburg, president of the Cumberland Valley Telephone Company.

F. A. Wunder, of Philadelphia, general manager of the Keystone State Telephone and Telegraph Company, chairman of the reception committee, took charge of the delegates as they arrived. Other members of the reception committee were:

Willard P. Beardsley, of Harrisburg, district superintendent of the United Telephone and Telegraph Company; W. H. Wilson, of Erie, general manager of the Union Telephone and Telegraph Company; Cameron L. Baer, of Harrisburg, manager of the local office of the United Telephone and Telegraph Company, and W. H. Denlinger, of Patton, president of the Huntingdon and Clearfield Telephone Company.

When the old executive committee met on Tuesday morning the following committeemen were selected, being announced and ratified at the organization meeting that evening:

Nominations—Edward Davis, of Philadelphia; A. F. Moses, of York; E. D. Schade, of Johnstown; John M. Core, of Uniontown, and S. G. Latta, of St. Mary's.

By-Laws and Constitution—Robert E. Flinn, of Pittsburg; J. P. Conley, of Cresson, and C. E. Wilson, of Philadelphia.

Program—F. D. Houck, of Philadelphia; O. S. Marshall, of Rural Valley, and H. E. Bradley, of Philadelphia.

Toasts—W. D. Barnard, of Philadelphia; J. G. Splane, of Pittsburg, and C. E. Wilson.

Secretary Bradley was enthusiastic over the response to the invitations scattered throughout the State and said emphatically to the correspondent for the AMERICAN TELEPHONE JOURNAL that the meeting was more of a success than the promoters had anticipated.

Hon. Vance C. McCormick, the reform Mayor of Harrisburg, welcomed the telephone men to the Capital. He took occasion to speak of the entrance into the city of better and cheaper telephonic service through the lines of the Independent people. When a member of the city councils of Harrisburg, he said, he had the honor of supporting an ordinance granting a franchise to an Independent telephone company. It was this franchise which, while briging money into Harrisburg's city treasury, also brought the improved and cheapened service in the telephone business.

W. H. Denlinger, of Clearfield, responded to the Mayor's address of welcome in appropriate terms and briefly explained the objects of the association. He declared that Independent telephony had come to stay and that while it had already conferred inestimable benefits upon the public by establishing telephone lines where none existed before, by cheapening the cost of telephonic communication to the user and by greatly improving the service, organization of the various telephone companies for thorough inter-communication will confer still greater benefits upon the people and enable the companies to extend and improve their lines.

James B. Hoge, of Cleveland, O., spoke of the pleasure which it gave him to extend to the Pennsylvania State Independent Telephone Association greetings from the National Independent Telephone Association of America. "You enjoy the distinction of holding the first convention to organize along the line planned at the St. Louis convention last week," he continued.

Mr. Hoge then told of the success of that convention and followed with a detailed account of its doings, a full story of which has already been printed in the THE AMERICAN TELEPHONE JOURNAL.

Mr. Hoge emphasized the good results to be obtained from dividing a State into districts. This action was taken last June in Ohio, when the State association was reorganized. A number of small Independent companies were found which had never affiliated with the State body.

There are two classes of membership in the association—active and associate. The first receives officers or directors of any Independent telephone company included in the scope set forth in the by-laws, the annual fee being $10. The second receives any one connected with an Independent telephone company, the member paying an annual fee of $1 and having all privileges except the ballot. By special arrangements a subscription to THE AMERICAN TELEPHONE JOURNAL goes with each membership.

A. L. Têtu, of Louisville, Ky., was particularly outspoken in the effect upon the telephone business of the National Independent Association when the several States had been well organized and could co-operate thoroughly with the National body.

Pennsylvania, he said, being the first to organize along the lines of the St. Louis plan, the lead must be followed in other States. Then the National body will ultimately become the weapon of offense and defense for which the leading Independent hope.

Digitized by Google

Secretary Bradley said that an important provision in the by-laws, which in the main are similar to those suggested at St. Louis, was that officers or employees of telephone lines operating in contiguous territory could become members of the Pennsylvania association. This extends the field to including New York, New Jersey, Delaware, Maryland, Virginia or West Virginia, if desired. The provision was made in order to extend a helping hand to States like New Jersey, Delaware, Maryland or West Virginia, where it is thought the Independent lines are not sufficiently strong to maintain a separate State association at the start.

I. D. Gindhart, Jr., of Philadelphia, was introduced and made an address to the convention upon "Telephone Auditing." Mr. Gindhart's speech, together with those by Mr. C. E. Wilson, general manager of the Keystone Telephone Company, of Philadelphia, Charles Russell, of Philadelphia, and Mr. H. E. Bradley, secretary of the association, will be published in the next issue of THE JOURNAL.

In 1895 the Bell people had in their employ practically every one who knew anything about telephony. They had all the patents. The Independent people had to make men to make their machines. In nine short years the number of Independent telephones has grown to more than 2,400,000—ten times as many as the Bell system had from '77 to '95. To-day the Bell system embraces about 1,250,000 telephones, but in the annual reports of the company one telephone is counted as two—the receiver and the transmitter each being counted as a single telephone.

No business, Mr. Critchfield went on to say, is so absolutely certain of profit for the investor as the telephone. The business is not affected by hard times, for the telephone is one of the last things to be dispensed with. A man will have one or two less radiators, or consume a little less coal or burn a few less lights in order to keep his telephone. He cannot do without it; it is a necessity as a money saver.

in organizing the Independent telephone companies and because these men would not dare to ask their neighbors to buy what they themselves would not buy there is $125 dollars of value for every $100 invested in the Independent companies.

To-day it is impossible to meet the demand for telephones and three long-distance calls are registered for every letter bearing a 2-cent postage stamp which is carried by the United States mail. The people cannot wait for the telegraph and the mail.

Treasurer Hall, of the Pittsburg and Allegheny lines, emphatically declared the paying qualities of the Independent lines to be a business which has proven its ability to pay from 3½ to 5½ per cent. interest.

Quoting Franklin, he said all of the companies must hang together or they will hang separately. The Independents, disorganized, are up against organization all over the country, but we are bringing them to centralization. The experience of nine years has proven that we are not on a false basis; it is one of utility; it is one of firmness; it is one of growth.

Wipe out the Independent telephones of the country to-day, Mr. Hall said, in concluding, and the business machinery would stop. The Bell lines could not handle the trade.

A. L. Têtu, of Louisville, Ky., general manager of the Louisville Home Telephone Company and the Independent Long Distance Telephone and Telegraph Company, was introduced when the members had quieted down after vigorously applauding Mr. Hall.

Mr. Têtu said that for two years the Independents have been in Louisville. When the exchange was established there the number of telephones in the city numbered 2,000; now there are 14,000, the Independents having 1,000 more of them than the Bell.

Mr. Têtu's remarks were brief and confined chiefly to the fights by the Independent companies since he left the Bell several years ago. He attributes the success in Louisville to the fact that the interests are localized.

The toastmaster concluded by introducing Former Governor William M. Bunn, of Philadelphia.

Mr. Bunn's address was confined principally to Philadelphia, he being inordinately proud of the Keystone State and its Eastern metropolis, and the work being done in that part of the State furnished the basis for the eulogy of the city.

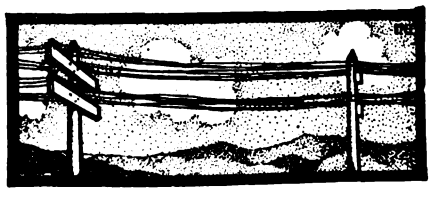
J. B. Hoge, of Cleveland; J. B. Ware, of Detroit, and Captain William Thompson, of Philadelphia, all spoke briefly.

Major Lewis E. Beitler, deputy secretary of the Commonwealth of Pennsylvania, was the last speaker. The Major's popularity was quickly shown as his tall form loomed up above the height reached by any previous speaker, and he was immediately presented with a potted pine tree about twelve feet high. Major Beitler said it reminded him of the proverbial "plum tree."

He complimented the Independent telephone association and expressed the greatest satisfaction with its service. This service, he said, is much better than that given by the Bell companies.

QUERIES

Questions on any subject relating to telephony will be answered on this page.



INDUCTION COIL DESIGN.—(432.)

Fig. 888 represents an induction coil. *C* is a rolled condenser six inches long. *A* and *A* represent an iron core wound around *C*. Primary and secondary are then wound around *A*, *B* and *B'* are terminals of *C*. *B* goes to *P* and *B'* to *S*.

In reference to the merits of the induction coil, which you describe in your letter of recent date, it would appear that a rolled condenser, such as you describe occupying the center of the coil,

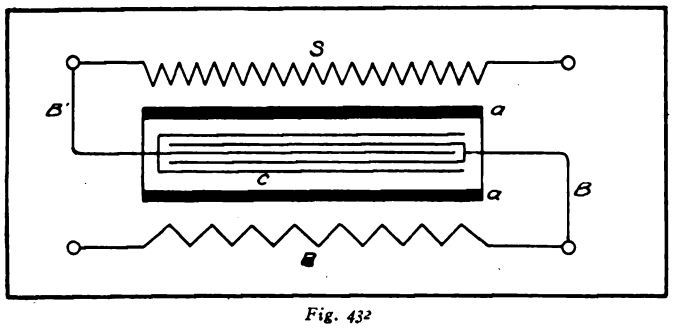


Fig. 432

would require considerable space. That is to say, would be from an inch to an inch and a half in diameter, depending upon the capacity of the condenser. It would then be necessary to wind the induction coil upon the outside of this condenser and consequently the turns of the coil would be long as a result. Either the wire must be very large or else the coil would possess an undesirable resistance, and in any event the wire would be much longer than would be required, by a coil of a regular core. Thus the cost of the coil would be increased either by the use of larger wire or by the use of longer wire or both, and as there are no advantages, we should consider this form of coil undesirable.

GUYING POLES.—(433.)

Will you please illustrate the correct method of guying poles by means of a guy pole? L. M. G.

The correct method of guying poles is dependent entirely upon the conditions which exist at the point of the line where a guy wire is necessary. It is therefore evident that under certain conditions different methods are necessary. The only object to be gained in using a guy stub is to raise the guy wire. The general method used is illustrated in Fig. 433, in which *B* is the more correct position of the stub. Where the pole placed as at *A* and the guy anchor gives way, the pole which it is intended to pro-

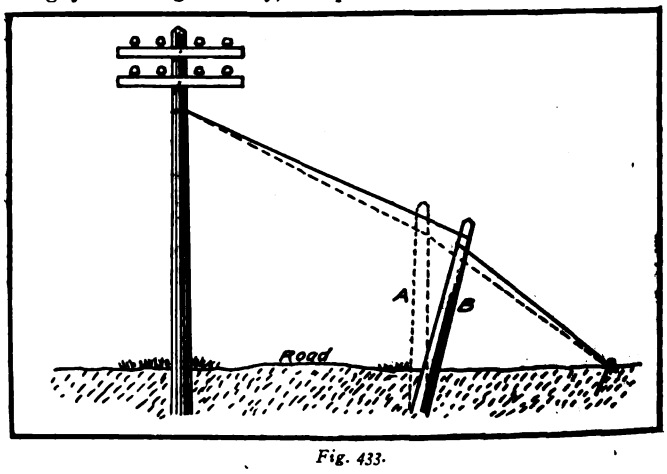

Fig. 433.

tect would pull the guy stub over and possibly out of the ground, whereas if the stub is in the position *B* there is a larger amount of compression upon it due to its position, and it is therefore able to aid the anchor by offering a greater opposition to the strain of the guy wire than it could were it in the position as shown at *A*.

TRANSPOSITION.—(434.)

Kindly advise me if you can furnish me with blue prints of transpositions of different types. I refer to specifications such as are used by long distance toll companies. Also advise me where I can get them if you cannot furnish them. W. W. L.

IN our previous issue we published two diagrams of transpositions for six and ten pin arms. A full set of instructions for transpositions is published in Mr. A. V. Abbott's book upon Telephony, Volume IV, to which we would refer you for further information.

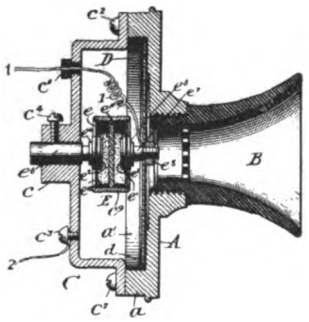
TELEPHONE PATENTS

TELEPHONE TRANSMITTER.

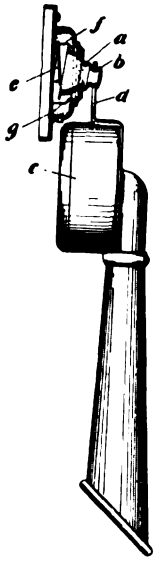
J. W. Lattig, of West Bethlehem, Pa., and C. L. Goodrum, of Philadelphia, Pa., patent (No. 769,702) a telephone transmitter and assign to the Eastern Telephone Manufacturing Company, of West Chester, Pa. This invention relates to granular telephone transmitters and has for its object improvements which will enable a more powerful high resistance transmitter to be constructed. The inventors provide a face plate *A*, to which the mouthpiece *B* is attached. The bridge *C* is secured in the usual manner across the face plate. The rear electrode *e2* is carried upon a stem *e6*



secured in a bearing upon the bridge by means of the screw *c4*. The front electrode *e3* is carried upon the stem *e8* secured in the usual manner. A capsule containing the granular carbon is suspended upon the two electrodes by means of two flexible mica diaphragms which cover its ends. In the center the capsule is divided into two parts by means of a diaphragm *e11*. By this means the effects are secured similar to those of a double button transmitter.

AN IMPROVED HOOK-SWITCH.

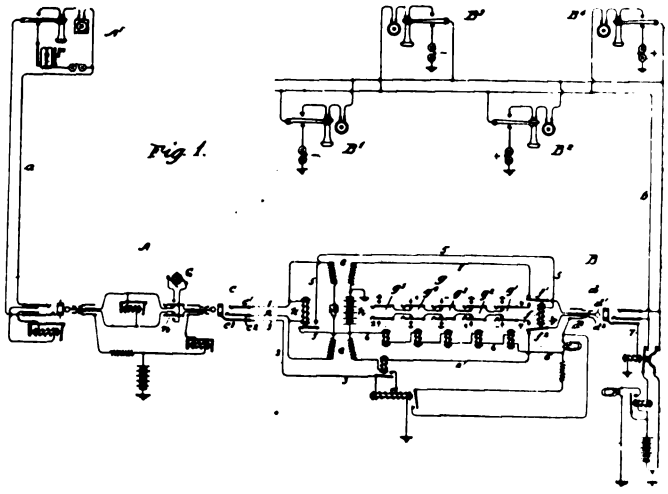
W. A. Hjorth, of Stockholm, Sweden, patents (No. 769,084) and assigns to Elektromilitara Aktiebolaget, of Stockholm, Sweden, an improved hook-switch. The object of this invention is to provide an improved switching device to take the place of the ordi-



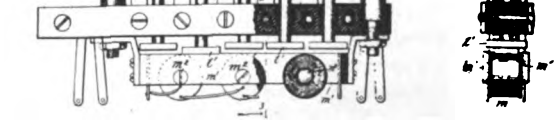
nary hook-switch in substation apparatus. As is shown in the accompanying illustration, the inventor provides an oscillating button, *A*, having a projecting knob, *B*, upon which the transmitter may be supported by means of a hook. The oscillating knob, *A*, operates a contact spring, *B*. When the transmitter is hung upon the button, the knob rolls in its socket and operates the contact.

RINGING ON TRUNK LINES.

J. L. McQuarrie, of Chicago, Ill., patents an improved trunk line circuit (No. 769,763) and assigns to the Western Electric Company of Chicago. The intention of this invention is to provide a switchboard circuit whereby the answering operator can ring a subscriber in a distant office over a trunk line. The



essential features of the ringing key are shown in Figs. 2 and 3, while the switchboard circuit is shown in Fig. 1. As is shown in Figs. 2 and 3, the inventor provides a key having a number of plungers, each of which when depressed is locked in place by means of an electromagnet, and by the springs *g2* in Fig. 3 connects the line with such a particular kind of ringing current as is adapted to signal the party desired. The system is best understood by describing its operation. When an answering operator at the *A* board (*A*, Fig. 1) desires a connection with a line which terminates in a distant office at the *B* board, she inserts the calling plug into the trunk line jack *c* and orders the connection over an order wire in the customary manner. The operator at the *B* board inserts the plug *d* into the jack of the desired line and de-



presses one of the plungers *g1*, *g2*, *g3*, *g4* or *g5*, as may be adapted to call the particular party. The *A* operator then manipulates the ringing key *n*. This sends ringing current over the trunk line and through the relay *k*, which closes the contact *5* of the local circuit operating the electromagnetic switch *f* and thus connects the ringing current to the called line. As the plunger of the ringing key is held in position by the magnet *m* (Figs. 2 and 3), the key cannot be set until the plug is inserted in the called line, but after its insertion the plunger remains depressed and the ringing current applied until the subscriber has removed the receiver from the hook.

TELEPHONE OPPORTUNITIES IN THE FOREIGN FIELD.

WITHIN the past few years the products of American genius and skill have reached to the most remote parts. One finds in Central Africa a bridge made and installed by an American firm. In the back country of Australia the sheep herders live in galvanized iron bungalows imported from the States and out in the South Pacific seas the natives use hunting goods which bear the trade marks of some New England factory.

In telephony the United States is pre-eminently the leader, and with few exceptions the apparatus of the world is copied from American models. This being the case, it would seem that the telephone manufacturers should be able to supply a major part of the large amount of apparatus which is now being secured in Europe and other parts of the world.

In the August Consular Report the United States Consul at Leipzig, Germany, stated that the Guatamalan Government contemplated considerable extensions to its telegraph and telephone systems and the Consul-General at Frankfort, Germany, reported that the Spanish Government was about to establish telephone systems in seven Spanish cities. Sartaro Oi, in his paper presented to the recent International Electrical Congress, estimated the opportunities for American telephone apparatus in Japan.

Quite recently a contract was placed by the Compania Telephonica do Estado de S. Paulo, of San Paulo, Brazil, with the International Telephone Manufacturing Company, of Chicago, for a 4,000-line capacity self-restoring drop generator-call multiple switchboard. The present equipment calls for the immediate operation of 1,500 lines, built in five three-position architectural iron sections and including a complete power plant, storage battery set, power switchboard, together with main and intermediate distributing rack, lightning arrester and sneak current protectors, all complete, ready for installing.

The board to be furnished will be equipped with the latest type self-restoring drops, with pilot lamps, proper busy tests, etc. The investigation that led up to this contract was made for the telephone company by Eduardo de Aguiar D'Andrada, chief electrical engineer of the S. Paulo Railway Company, and Edgard de Souza, chief electrical engineer of the S. P. T. Light and Power Company.

This apparatus is for replacing and greatly enlarging the company's present system, the plant to be extended to cover the entire city of S. Paulo, which at the present time has a population of nearly 100,000 inhabitants.

Here is an illustration of what the American manufacturer may look for in the South American telephone field. There are scores of cities down there as active as any communities in the world almost, and not one of them should be equipped with apparatus that hails from any country except the United States.

TAXING TELEPHONE COMPANIES IN INDIANA.

INDIANA has one of the best tax laws of any State in the Union and provides that telephone companies file a report in July of each year with the State Tax Board, which holds a six weeks' session to value these properties and equalize the taxation or rate levied by local tax officers. These reports are required to show the mileage of wire, number of miles of poles, number of poles per mile, kind of wire, kind of poles, how long in use, size, etc., number of switchboards, number of telephones in use, number of employees and officials, amount paid for wages and salaries, the gross and net income, amount expended in extensions or improvements, value of real estate, etc. In July, 1903, 182 telephone companies reported to the tax board, and in July, 1904, 252, a gain of 70 companies for the year. In 1903 there were 125,536 miles of telephone wire strung in Indiana and in 1904, 146,212 miles, a gain of 20,676 miles during the year.

In 1903 there were 77,278 miles of wire strung in Indiana by the allied Bell companies and 47,258 miles owned by the Independent companies. In 1904 the allied Bell companies had increased their mileage to 83,026 and the Independent companies to 63,186, the gain of the Independent companies being nearly three times that of the Bell companies.

The tax board fixed the assessments on the telephone companies about the same as last year, with the exception of the Central Union Telephone Company, whose assessment was reduced from $56 to $54 per mile. This was done on the strength of the "poor month" story related to the board by its legal representative to the effect that the company's lines and poles were old, much of the equipment antiquated, fixed charges heavy and the opposition in localities destructive.

ENCOURAGEMENT FOR AMERICAN MANUFACTURERS.

CONTRACT AGAINST PUBLIC POLICY.

ACTION or damages was brought by J. B. Gwynn against Citizens' Telephone Company of South Carolina. The plaintiff alleged that he had demanded from the telephone company the use of the Citizens' telephone in his store and that the defendant company willfully refused him the use of the telephone, unless he would consent to a prohibition against the joint use of the telephone of the Southern Bell Telephone & Telegraph Company. He refused to consent to this prohibition. The defendant denied the allegations of negligence and willfulness and gave as an excuse that at the time the demand was made upon it by the plaintiff, its switchboard and lines were so crowded and there were so many demands upon it that he could not comply with the plaintiff's request.

The defendant also set up as a counter claim the breach by the plaintiff, prior to the demand upon which the plaintiff was sued, of a written contract by which the plaintiff agreed to use the telephone exclusively in his place of business, the defendant alleging that the plaintiff used another telephone and refused to comply with the terms of the contract. The plaintiff moved to strike out the allegations of the answer, on the ground of insufficiency. The trial judge permitted the allegations set up as a defense, but sustained the demand of the counterclaim. The plaintiff received a verdict for $400.

The Supreme Court held that the counterclaim was connected with the subject matter of the action, as it was the foundation upon which the defendant based his refusal, but allowed the plaintiff the further use of the telephone. The court held, however, that the contract alleged in the counter claim was void on the ground that it was in restraint of trade and against public policy. The modern doctrine is that contracts between individuals are not void, on the ground that they are in restraint of trade, unless the provisions thereof are unreasonable. The contract alleged in the counter claim was unreasonable, because its tendency was to stifle competition between carriers and to create a monopoly in favor of the defendant. The Supreme Court therefore refused the judgment of the Circuit Court, and remanded the case.

The Telephone in the Courts

Conducted by A. H. McMillan.

Readers are invited to submit questions on any point of Telephone Law. They will be answered and explained on this page.

CROSSING RAILROAD RIGHT OF WAY.

High Point, N. C.

Several months ago in building a copper toll line, we crossed and placed two poles on railroad right-of-way which is 200 feet in width. The railroad company is now trying to make us sign contract with them in which we are to move the poles off their right-of-way, use insulated wire and at a height of 33 feet and to remove the line entirely whenever called upon. Is this a fair contract? Can railroad company remove our line or prevent us from crossing?

THE railroad company can remove your line and prevent you from crossing, just as a private individual can. However, you have the right to secure a passage across their right-of-way by condemnation proceedings in case of inability to reach an amicable understanding. The fairness of the contract depends largely upon local conditions, but it seems that the use of insulated wire and the stringing of the wires at the height of 33 feet above the ground are fair provisions, made necessary by the railroad company's duty to protect its employees. In case you should have to resort to condemnation proceedings it would be cheaper for you not to set the poles upon the railroad company's right-of-way if you can cross it without so doing, because you would be compelled to pay damages to the amount of the value of the land actually occupied by the poles, and not that lying under the wires. St. Louis & C. R. Co. vs. Postal Teleg. Co., 173 Ill., 508; 51 N. E., 382. The provisions of the contract requiring you to remove your line entirely whenever called upon seems too advantageous to the railroad company if a permanent removal was meant. If, however, the provisions were draughted so that you are only to move the line temporarily when necessary, it would not be unreasonable.

MISS BREWER BEAT TELEPHONE CO.

TO prevent the New England Telephone Co. from putting a pole in front of her house, Miss Emilia F. Brewer, of Stockbridge, Mass., who will be 70 years old in three weeks, and who is a sister of Associate Justice David Josiah Brewer of the United States Supreme Court, sat in a hole 18 inches deep all one afternoon and during the night slept in a tent over the hole. Her dinner and supper were brought out to her by a maid. During the afternoon, by order of the Stockbridge selectmen, a deputy sheriff carried Miss Brewer bodily to the house and just as he reached the front door she broke away and sat down in the hole again. During all of the afternoon the selectmen tried to get her to give up; leading cottagers of the town called upon Miss Brewer, extended their sympathy, and said they hoped she would defeat the telephone company. Miss Brewer won her case against the New England Telephone Company, the selectmen of Stockbridge, and Egbert Yale, one of the wealthiest and best-known citizens of the town. The selectmen and Mr. Yale gave their consent to have the pole located just across the road from Miss Brewer's estate, and she ended her vigil. For 44 years Miss Emilia Brewer has been a teacher. She was in South Africa for six years; for 17 years she was an instructor for the mountain whites of northern Alabama, and for a number of years she was on the plains of Kansas and Nebraska. For the past two years Miss Brewer has been an instructor for the blind at the Industrial Home for the Blind in Hartford, Conn.

KNOWLEDGE OF DANGEROUS CONDITION.

WHERE an electric company negligently fails to insulate its wires so that an adjacent fallen telephone wire becomes charged with a deadly current and causes death, the electric company is liable, without regard to its actual knowledge of the fallen wire, for its diligence in discovering it. This was the holding of the Supreme Court of South Carolina in an action brought against the Charleston Consolidated Railway, Gas & Electric Company and the Gordon Telephone Company for causing a person's death. The plaintiff alleged that her intestate's death was caused by coming in contact with the wire of the telephone company which had fallen across the electric company's wire and was highly charged with electricity. The liability of the telephone company was not involved in the appeal. The electric company demurred to the complaint and appealed from an order overruling the demurrer.

The ground of the demurrer was that it was not alleged in the complaint that the electric company had knowledge of the fact that one of the telephone company's wires had broken and fallen across one of its own wires, or that sufficient length of time had elapsed for the breaking and falling of said wire to have been discovered by the electric company by due diligence or proper care. The court sustained the order overruling the demurrer, holding that the extent to which the wires conveying deadly electric currents should be insulated or otherwise guarded, must be decided by the jury under the facts of each case. In determining the danger it is the duty of those in control to have in view all the surroundings, including the contiguity of the wires, the liability to fall, and the coming in contact with dangerously charged wires. "Hence, when the plaintiff states that the discharge of the fatal current from the electric company's heavily charged wire through the telephone wire was due to the defective and negligent insulation, a good cause of action is stated." Parsons vs. Charleston Consol. Ry., Gas & Elec. Co., (S. Carolina) 48 S. E. 284.

ANOTHER CASE INVOLVING KNOWLEDGE OF DANGEROUS CONDITION.

IN another case involving a telephone company the Supreme Court of South Carolina held that knowledge of the dangerous condition, which in this case was the obstruction of a highway by telephone wires, was an important element in determining the defendant's liability. A little girl, by her guardian ad litem, sued the owner of the telephone line for negligently allowing a telephone wire to sag across the highway and remain in such condition for ten days. The plaintiff, accompanied by her mother, passed along the highway, driving in a top buggy, and without any fault on her part, the wire caught the top of the buggy in which she was riding, turned it over and threw her to the ground, inflicting upon her severe bodily injury. The defendant secured a verdict and, the plaintiff appealing, the decision of the lower court was reversed. One of the reasons alleged by the plaintiff for revision of the judgment was the refusal of the judge to charge that the question of notice to the owner of the line, as to its condition, could not be considered by the jury. On this point the court held that the request to charge was properly refused. The difference between the holding of the court in this case and in the one previously mentioned is caused by the different state of facts.

The court also decided that where the plaintiff states all the facts necessary to make out a cause of action, it need not refer to the statute nor set out its terms. It is a question of law for the court, and not one of fact for the jury, whether a person is required by statute to remove an obstruction from a highway. In an action under the statute to recover damages for obstructing a highway, recovery does not depend upon negligence; but for obstructions not forbidden by statute, it is encumbent upon the plaintiff to show that she not only suffered injury which was caused by defendant, but that such injury was the result of negligence. Smith vs. Gilreath, (S. C.) 48 S. E. 262.

IN THE OPERATING FIELD.

SOUTHERN INDIANA INDEPENDENT TELEPHONE ASSOCIATION.

THE fifth annual meeting of the Southern Indiana Independent Telephone Association was held at Rockport on September 26th and 27th. The attendance was fairly good and the interest manifested was greater than at any previous meeting. It was the intention to hold an afternoon session on the first day, but owing to the late arrival of President C. D. Knoefel, of New Albany, the regular programme was not taken up until the night session. The afternoon was spent in making up the enrollment and looking over the large and interesting displays of the supply companies.

The evening session was held in the court-house, where a general discussion was had of the "Needs of Independent Telephone Companies in Southern Indiana" and how to bring about a better toll line service between the local exchanges. It was argued that greater harmony should prevail and a more determined disposition to effect universal co-operation in the extension of the service. During this discussion experiences were exchanged and numerous plans suggested for the betterment of the service throughout the southern half of the State. The delegates and visitors were next escorted to the city hall, where an elaborate banquet was held. The banquet had been planned as the culminating feature of the notable meetings held by the Southern Indiana Association. The committee of arrangements had devoted great care and attention to the details, and the result fully justified it all. The after-dinner speaking began most happily and continued throughout the evening. A. J. Payton, manager of the Home Telephone Company, of Spencer County, acted as toastmaster. H. J. Cole, of Owensboro, was the first speaker of the evening, his subject being "Our Guests." Other subjects and speakers were as follows: "What Shall the Harvest Be," by H. Landgrebe, of Huntingburg; "The German Language on the Telephone," by Frank Beaucound, manager New Albany Home Exchange; "How Should the Telephone Be Managed," by J. L. Arthur, Indianapolis; "The Supply Men," by F. M. Thorn; "Telephone Finance," by C. D. Knvefel, president Southern Indiana Telephone Company, of New Albany. The speeches were all listened to with interest and profit, as it was evident that several of the speakers had made considerable preparation. It was shown that the telephone business is being handled in a much more practical and satisfactory manner than a few years ago.

The morning and final session of the second day was devoted to miscellaneous business. Owing to the fact that many of the Independent companies have been merged and consolidated the attendance throughout was not as good as formerly. The election of officers resulted in the re-election of Charles D. Knoefel, of New Albany, president, and E. W. Landgrebe, of Huntingburg, secretary

THE NEW UNION TELEPHONE COMPANY OF ERIE.

THE Union Telephone Company of Erie, Pa., which was recently formed to conduct a long distance telephone system, has acquired the system of the Union Telephone & Telegraph Company, which comprised several exchanges and 600 miles of toll lines, by purchase at a recent meeting.

The new company has under its management about twenty exchanges, with nearly 4,000 telephones, and about 600 miles of pole lines connecting with the city of Pittsburg on the south, and Cleveland on the west, and very soon will have connections with Buffalo on the east. It reaches as far east as Riply, N. Y.; also Bradord, Pa., and Olean, N. Y. It also has lines from Erie to Kane and reaches all principal points in Elk county. The lines also run from Bradford to Kane.

Lines are run through Union, Corry and Warren to Kane, having connection with all the Independent exchanges in these towns, and also to Girard and Conneaut, connecting with lines to Ashtabula and Cleveland. From Girard they run south and go through Linesville, Jamestown, Sharon and New Castle and on to Ellwood City, where they connect with the Pittsburg lines, and from Corry to Titusville, where they connect with the Petroleum exchange, giving service to Oil City, Franklin, Sharon and New Castle.

The company is at present busily engaged in putting up $30,000 worth of No. 10 copper wire, which when completed will give unexcelled communication with not only Pittsburg and Cleveland, but very shortly with Buffalo.

P. & A.'S CONNECTION WITH WEELING DELAYED.

VARIOUS difficulties have prevented the Pittsburgh & Allegheny Telephone Company and the National Telephone Company of Wheeling from completing the connections between the two cities as soon as was expected. It is probable November 1 will see the line in operation. It will add 3,000 telephones at Wheeling to the list reached by the Pittsburg Independent company.

The new line is being built from Bridgeville straight toward Wheeling on a private right of way, making the distance about fifty-eight miles from Pittsburg.

The connection at Wheeling not only gives the list of 3,000 in that company's directory, but gives further connections in West Virginia and Ohio, which makes the additional telephones connected total 10,000.

NEWARK TELEPHONE COMPANY DECLARES A DIVIDEND.

AT the last regular monthly meeting of the Newark (Ohio) Telephone Company it was voted that a quarterly dividend of one per cent. be declared to holders of the company's common stock. The regular semi-annual dividend of three per cent. will be paid on the preferred stock on the first of January.

The Newark Telephone Company has opened up its new toll line to Gratiot, which exchange already gives service to a large number of subscribers at Gratiot, Brownsville, Mount Perry, Linnville, Mount Sterling and White Cottage. All of these telephones have been installed during the past two months.

These telephones are connected with the central exchange at Gratiot and are there switched on to the lines of the Newark Company.

With this connection the new company now gives toll service to every village and almost every cross road in the country, and also over 1,700 telephones in Newark and Granville.

HOME COMPANY OF CARTHAGE, MO., MAKES TRAFFIC AGREEMENT.

THE Home Telephone Company of Carthage, Mo., has entered into a contract with the Red Oak, Meinert & Lockwood Telephone Company, a mutual company, covering the northeast section of the county, for traffic purposes. The main switchboard is located at Maple Grove. There are about one hun-

Digitized by Google

dred farmers in that vicinity who will be given free connection with Carthage. The company will build a new line in a northeasterly direction to accommodate rural subscribers to Carthage exchange. It is expected that the line will be in operation in the next sixty days.

Carthage subscribers to the Home Telephone Company have over 700 connections in the town and something like 2,300 to 2,400 outside; besides the Home Telephone Company can furnish connections with Kansas City and St. Louis and intermediate points.

POPULARIZING THE TELEPHONE.

IT has remained for Independent telephone companies to popularize the use of the telephone. That they have succeeded in an admirable manner is certain from the large number of subscribers to their systems. This result is due in a great measure to the methods of advertising employed to secure publicty. A case in point which demonstrates clearly what is wanted is here-

Theatre Telephone Service of The Evening Telegraph Information Bureau

CALL UP KEYSTONE—MAIN 1800—IF

—You want to know what attraction plays in a certain house a certain week.
—You want seats engaged for a given performance.
—You want to know what plays your favorite actors and actresses are to appear in this season.
—You want to know prices of seats in any theatre for any performance.
—You want a diagrammatic description of seats concerning which the numbered location is in doubt.
—You want to know where and when any theatrical attraction is opening the season.
In short, if you want ANY sort of information about ANYTHING theatrical,

CALL UP KEYSTONE—MAIN 1800

with shown. The Keystone Telephone Company has furnished numerous ideas which are well worth consideration by all Independent companies, and this idea of advertising theatre service is not the least of these. To the theater-going public it will be a boon and will at the same time fix firmly in the minds of the people who are interested, the great value of an up-to-date Independent system.

DISSATISFACTION WITH CUMBERLAND IN TENNESSEE.

THERE is dissatisfaction and complaint over the actions of the Cumberland Telephone & Telegraph Company among subscribers at Ashland City, Tenn. When the exchange was put in about four months ago, in order to get a sufficient number of subscribers to justify the establishing of the system, the contracts entered into with the subscribers provided that communication should be had with all points in this county where there is a telephone, without extra charge to the subscriber. This was to be allowed even when the calls had to go through the Nashville and Clarksville exchanges, but now it is proposed by the company to cut out those places in the county which have to be reached through Nashville and Clarksville, and charge the subscribers the regular tolls for this service.

DECORATIONS AT BANQUET OF PENNSYLVANIA ASSOCIATION.

THE decorations at the banquet of the Pennsylvania State Telephone Association convention at Harrisburg, Pa., which evoked expressions of admiration on all sides, were peculiarly applicable to a telephone dinner.

Stationed immediately before the stage in the auditorium of the Harrisburg Board of Trade Building was a circular table, a dozen feet in diameter, the toastmaster's table. Resting upon this was an exact reproduction, on an enlarged scale, of a desk telephone set, worked in flowers and smilax. .

Flanking the toastmaster's table to right and left, were two large tables, extending to either side of the hall. Taking the center table with its desk set as an imaginary exchange, complete sections of a telephone line in miniature radiated along the flanking tables. Everything about these line sections was on a scale of about one-fifth.

The poles were swathed in moss and smilax. The cross-arms, one to each eight poles, bore seven small incandescent electric lights, representing the insulators. These lights were pointed upward, the larger ends being frosted. The reflected light glistened from copper wire, new coils having been taken from stock to heighten the artistic effect.

This unique idea, as well as the general scheme of decoration, was evolved by Willard P. Beardsley, of Harrisburg, district superintendent of the United Telephone and Telegraph Company, who was given *carte blanche* by the executive committee. The work was done under Mr. Beardsley's direction by a corps of men from the Harrisburg United office, superintended by Granville S. Herbert, wire chief.

A copy of the coat-of-arms of Pennsylvania was suspended at the rear of the stage, an orchestra being placed directly in front, entirely concealed by a bank of potted plants, among the branches of which dozens of small green incandescent lights glimmered.

Cut flowers stood about in dozens of vases and a carnation boutonniere reposed at each place. Each guest received as a souvenir a miniature telephone receiver, one and one-quarter inches long, pendant from a ring for use as a watch charm. Miniature switchboard plugs of the same length were distributed also. The menu cards were of deep blue, cut in keystone shape, bearing a cut of a desk set, with the occasion and date upon the front cover.

INDEPENDENT LONG DISTANCE LINES.

EVERY effort is being made to complete connections by means of long distance toll lines between the Independent systems of the Central States at the earliest possible moment. Quite recently a long distance line was built from Richmond, Ind., to Dayton, Ohio, and lines are now being rapidly pushed forward to connect the system in Ohio and Indiana with Kansas City and other towns in the Southwest. Indianapolis and St. Louis are already connected and extensions are being built that will connect the companies in Pennsylvania, Maryland, New Jersey, and New York with the vast system of Independent lines which are rapidly forming a network over the whole country.

CONGRESS PAPERS.

MEMBERS of the International Electric Congress of St. Louis can receive copies of any Congress paper, or papers, in which they are interested, and which were printed in advance, by applying to Mr. H. H. Humphrey, Electrical Engineer, Chemical Building, St. Louis, Mo. Mr. Humphrey has kindly promised to distribute these papers on application until October 10th. We are also informed that written communications by way of discussions from congress members upon any Congress paper will be received by the general secretary, Dr. A. E. Kennelly, Harvard University, Cambridge, Mass., up to October 15th.

CUYAHOGA TO INTRODUCE STREET TELEPHONES.

THE Cuyahoga Telephone Company is considering the advisability of establishing public telephones upon the streets. As a test the company recently made application to the board of public service for permission to put up two telephones—one at the corner of Euclid and Bolton avenues and the other at the corner of Euclid and Sterling avenues.

The plan of the company is, if the permit is granted, and they prove successful, to operate a large number of public telephones in this manner. They will be the same as pay stations, except that they will not occupy the usual room of a pay station. They will be attached to posts, and in this way take up no more room than an ordinary telephone pole. The first two will be merely to see how the public takes to them, and if they will be of any public convenience, aside from the profits that might be derived.

TELEPHONE TESTS

By Dr. A. E. Kennelly.

Editor's Note: Dr. Kennelly's paper upon "Telephone Tests" was one of the most unique of the contributions to the Electrical Congress. It was original in describing a new apparatus for making telephone tests. In the past, telephonists have often been at a loss to devise methods of inspecting switchboards and other parts of a telephone plant. Dr. Kennelly's application of the barretter opens an entirely new field and one which from present appearances likely to be of much value.

The following appendices to Dr. Kennelly's paper are reproduced because they form an integral part thereof and because it is difficult and almost impossible to fully grasp the entire scope of the paper in their absence. While they are somewhat formidable mathematically, Dr. Kennelly has the happy faculty of writing mathematics so clearly, that with a little study these appendices may be readily comprehended.

APPENDIX I.

Theory of the Method of Measuring Alternating-Current Strengths by the Change of Barretter-Resistance to Direct Current.

Using the c.g.s. system for simplicity, and the connections of Fig. 6.

Let r = the resistance of the barretter b, when heated by the steady testing current (absohms).

$\triangle r$ = the small increase in the resistance r due to the superposition of the feeble alternating current.

I = the strength of the steady direct testing current (absamperes).

i = the effective or square-root-mean-square strength of the superposed alternating current (absamperes).

p = the power dissipated by the barretter b when traversed by the steady testing current (abswatts).

p = the small increase in power dissipated when the alternating current is superposed.

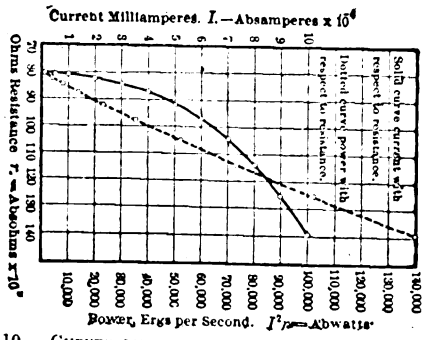

Fig. 10.— Curves showing relation between the resistance r, of a particular 1.7 μ barretter, the current strength, I, steadily flowing through the barretter; and the power I^2r dissipated in the barretter.

Then $p = I^2r$ abwatts.

$p + \triangle p = (I^2 + i^2)(r + \triangle r)$ "

$= (I^2 + i^2)(r + \frac{\triangle r}{\triangle p}\triangle p)$ "

$= (I^2 + i^2)(r + \frac{dr}{dp}\triangle p)$ when $\triangle r$ is very small "

$\therefore \triangle p = (I^2 + i^2)\frac{dr}{dp}\triangle p + i^2 r$ "

$\therefore \triangle p \left\{ 1 - (I^2 + i^2)\frac{dr}{dp} \right\} = i^2 r$ "

But $\triangle p = \frac{dp}{dr}\triangle r$ " " "

$\therefore \frac{dp}{dr}\left\{ 1 - (I^2 + i^2)\frac{dr}{dp} \right\}\triangle r = i^2 r$ "

$\left\{ \frac{dp}{dr} - (I^2 + i^2) \right\}\triangle r = i^2 r$ "

$i^2 = \frac{\triangle r}{r}\left\{ \frac{dp}{dr} - (I^2 + i^2) \right\}$ (absampere)²

By actual measurement it is found that in all cases p follows nearly a straight line with respect to r, see Fig. 10, and, at least within the range of r considered, $\frac{dp}{dr}$ becomes a constant for each particular barretter. Thus in Fig. 10, and near 10 milliamperes or $I = 10^{-3}$, $\frac{dp}{dr} = 2700$ ergs per ohm $= 2.7\times10^{-6}$ abwatts per absohm.

Let $\frac{dp}{dr} = b$ an approximate constant, which may be called the dissipation-resistance constant.

Then $i^2 = \frac{\triangle r}{r}\left\{ b - (I^2 + i^2) \right\}$

and $i = \sqrt{\frac{\triangle r}{r}}\sqrt{b - (I^2 + i^2)}$ absamperes.

Thus in the case of Fig. 10 for $i < 2$ milliamperes,

$$i = \sqrt{\frac{\triangle r}{r}}\sqrt{2.7\times10^{-6} - 10^{-6}}$$

$$= \sqrt{\frac{\triangle r}{r}}\sqrt{1.7\times10^{-6}}$$

$$= \sqrt{\frac{\triangle r}{r}}\ 1.304\times10^{-3}$$

For $\frac{\triangle r}{r} = 0.01$ or 1 per cent $\sqrt{\frac{\triangle r}{r}} = 10^{-1}$

$i = 1.304\times10^{-4}$ absamperes.

$= 1.304$ milliamperes.

Thus if $\sqrt{b - I^2} = c$ the barretter-constant,

then $i = \sqrt{\frac{\triangle r}{r}}\times c$ absamperes

$= \sqrt{\frac{\triangle r}{r}}\times c^1$ milliamperes

where $c^1 = c\times10^4$.

Or the alternating-current strength in milliamperes will be a constant times the square root of the proportionate increase in barretter resistance due thereto.

The sensibility of the method, or the minimum current which can be measured, depends upon the minimum proportionate increase in resistance $\triangle r/r$ that can be determined, and upon the magnitude of $b = \frac{dp}{dr}$ the dissipation per unit increase of resistance; also, in lesser degree, upon the strength I of the testing current.

When the barretter of Fig. 10 was sealed within an exhausted glass vessel, the testing current I was reduced to 1.5 milliamperes, or 1.5×10^{-4} absamperes and b to 90 ergs per ohm $= 9\times10^{-8}$ abwatts per absohm. From these values $c = 2.6\times10^{-4}$

$$i = \sqrt{\frac{\triangle r}{r}}\times2.6\times10^{-4}$$ absamperes.

If the least determinable change in resistance is 1/7000 of 1 per cent;

then $i = \sqrt{\frac{1}{700{,}000}}\times2.6\times10^{-4} = 3.1\times10^{-7}$ absampere

$= 3.1$ microamperes.

Digitized by Google

APPENDIX II.

Theory of Determining the Proportionate Increase in Resistance of a Barretter (and Hence the Alternating-current-strength) by a Milliammeter in Direct Series Circuit as in Fig. 5.

Let r = the res: of the barretter under steady test (absohms).
R = the res: of the barretter circuit steady test (absohms).
e = the e.m.f. of the dry cell (abvolts).
I = the steady testing current (absamperes).

Then
$$I = \frac{e}{R}$$
$$\frac{dI}{dr} = -\frac{e}{R^2} = -\frac{I}{R}$$
$$\therefore \frac{dI}{I} = -\frac{dr}{R}$$
$$\therefore \frac{\Delta I}{I} = -\frac{\Delta r}{R} \text{ when } \Delta r \text{ and } \Delta I \text{ are small}$$
$$\text{or } -\frac{\Delta I}{I} = \frac{\Delta r}{r} \times \frac{r}{R}.$$

The proportionate change in current as indicated by the milliammeter will be less than the proportionate charge in barretter by resistance in the ratio r/R

$$\therefore \frac{\Delta r}{r} = -\frac{\Delta I}{I} \times \frac{R}{r}.$$

In order to make the minimum $\triangle\frac{r}{r}$ observable, the resistance of the barretter should be as large a proportion as possible of the resistance of the circuit.

If $\frac{R}{r} = d$ a constant of the circuit
$$\frac{\Delta r}{r} = -\frac{\Delta I}{I} \times d.$$

By observing the proportionate diminution of current $-\frac{\Delta I}{I}$, the proportionate increase in resistance is thus deducible.

Theory of the Universal Shunt with Alternating Currents.

Referring to Fig. 6, let R be a constant non-inductive resistance constantly connected to the barretter b and condenser c. Let Z be the vector impedance of the condenser at the particular frequency or association of frequencies employed, absohms, $\angle$. Then the multiplying power of the shunt R permamently applied is

$$N = \frac{R+z+r}{R} \quad \text{(vector)}.$$

If now the contact t is shifted from f along R to some position distant electrically nR from a; then
$$N' = \frac{R+z+r}{nR}$$
$$= \frac{N}{n}.$$

If n be taken as $^1/_2$, $^1/_3$, $^1/_4$ etc.,
$$N' = 2N,\ 3N,\ 4N, \text{ etc.}$$

Consequently it is unnecessary to know the impedance Z offered by the condenser. It is sufficient to maintain the resistance R constantly connected, to calibrate the apparatus under this condition, and then obtain desired shunt by bringing out a contact-position at the corresponding point of the resistance R. The only drawback is the permanent reduction in sensitiveness of the apparatus by the constant shunting of the resistance R, even when the contact t is connected at f. If, however, $R = 2000$; while $(z+r) = 200 \angle 53°$

$$N = \frac{2126 \angle 4°.19'}{2000} = 1.063 \angle 4°.19'$$

so that the permanent loss of sensibility is only 6.3 per cent.

With the universal shunt applied, the formula for the instrument becomes

$$i = n N d c' \sqrt{\frac{\Delta I}{I}} \quad \text{milliamperes}$$
$$= nK\sqrt{\Delta I} \quad \text{milliamperes}$$

where n is the multiplying power of the universal shunt, K is the constant of the instrument with the full shunt R applied and the testing current I; while $\triangle I$ is the small diminution in testing current-strength (as read off in scale-divisions) due to the action of the alternating current.

APPENDIX III.

SERIES OF PRACTICAL TESTS WITH THE APPARATUS.

Since the paper was written, the engineering department of the American Telephone & Telegraph Company has made a series of tests with the apparatus from day to day, on a loop of open-wire circuit from Boston to Bedford, N. Y., and return, with a view to ascertaining the variations which might occur in repeating the received-current test on the same circuit day after day under conditions kept as nearly the same as possible. Owing to the fact that no high-frequency alternator has been available of sufficiently good regulation to afford a constant impressed voltage from day to day, the impressed voltage at the sending end had to be observed simultaneously with the current at the receiving end. The observations are tabulated below. It will be seen that the receiving-end impedance varied from 10,600 ohms to 13,000 ohms, being affected apparently by the insulation of the circuit.

TABLE I.

Date.	Impressed voltage.	Barreter number.	Insulation of circuit megohm-miles.	Shunt multiplier.	Deflection.	Receiving end impedance ohms
July 22	33.85	7	6.67	1.25	2.0	12,500

17	33.94	9	12.08	1.25	2.0	12,500

Circuit tests of loop of 384 miles of two No. 12 N. B. S. G. copper overhead wires (plus underground wires in Boston city limits). Resistance per loop mile, 10.5 ohms. Capacity per loop mile, 0.008 microfarad. Inductance per loop mile, 3.66 millihenrys. Insulation as above. Frequency about 300.

TELEPHONE SYSTEM FOR TROLLEY ROADS.

CONCTRACTS have been let by the Auburn & Syracuse (New York) Electric Railroad Company whereby a telephone system will be installed which will enable cars at any point on the line to communicate directly with headquarters at Auburn or Syracuse or any station along the line.

The company already has a telephone line between the two cities. Considerable difficulty was experienced last winter in locating cars which were in trouble along the line because the telephone system was not in use, and it is expected that all this will be obviated when the line is complete.

Each car operated on the line will have a portable telephone. By use of a jack plug connections can be made with the telephone system and conductors can telephone to any point on the line. Cars will be dispatched and receive orders by this system also.

Digitized by Google

THE WEEK'S MESSAGES

FINANCIAL.

COLLEGE CORNER, IND.—The Home Telephone Company of College Corner has increased its capital stock from $4,000 to $25,000. The company proposes to install new equipment and extend its lines.

DECATUR, IND.—The Citizens' Telephone Company of Decatur has increased its capital stock from $6,000 to $60,000. Extensive improvements will be made, new equipments installed including a new and up-to-date switchboard.

DES MOINES, IA.—The Boone County Telephone Company has given a mortgage for $50,000 to J. H. Herman as trustee to secure 5 per cent. bond issue to that amount.

MARION, WIS.—J. W. Hockenberger and Louis Goldberg, of Marion, representing the Marion & Northern Telephone Company, were in Shawano recently endeavoring to interest the citizens of that place in subscribing to a telephone system which their company proposes to install at Shawano. Statement is made of the investment of $1200 worth of stock by business men of Shawano would insure the construction of the system.

FRANCHISES.

SANTA MONICA, CAL.—A petition for a franchise for telephone and telegraph service in Santa Monica has been presented by Lewis Blakenhorn, representing the Home Telephone Company.

FULLERTON, CAL.—The city trustees have granted the Home Telephone Company permission to install a toll station in this city provided it agrees to connect with any new company that may install a local system.

MANITOU, COLO.—M. H. Spere and associates have been granted a 20-year franchise by the Local City Council to construct and operate an Independent telephone system. Articles of incorporation have been drawn up for the new company, placing the capital stock at $500,000.

HIGHSTOWN, N. J.—The Councilmen have agreed to grant the Farmers' Telephone Company a franchise providing it shall be so amended as to make the construction not less than $1500.

MIAMISBURG, OHIO.—The village council at a recent meeting granted a franchise to the Montgomery County Telephone Company.

SALEM, ORE.—W. D. D'Varney has presented a petition to the city council asking for a franchise to install a telephone system in Salem.

DALLAS, TEX.—F. B. McElroy and others have petitioned the city council for a franchise to construct and operate an Independent telephone system in Dallas for a period of twenty years. They offer a bonus of not less than $50,000 during the life of the franchise.

ELECTIONS.

NORTHVILLE, MICH.—The Northville Telephone Company has re-elected the old officers and directors. The reports submitted by the officers show the company to be in a prosperous condition, with 168 telephones in operation.

HANNIBAL, MO.—At a meeting of the Bluff City Telephone Company the following officers were elected: J. F. Davidson, president; T. G. Dulany, vice-president; H. C. Conger, secretary and general manager, and J. P. Hinton, treasurer.

JONESVILLE, N. Y.—The Clifton Park Telephone Company held its annual meeting and elected the following officers: Erastus R. Foote, of Jonesville, President; Norman Van Vranken, of Vischer's Ferry, secretary, and George Losee, of Elnora, treasurer.

HARRISBURG, PA.—At the recent convention of the Independent Telephone Association of Pennsylvania the following officers were elected: B. F. Meyers, Harrisburg, president; A. E. Flinn, Pittsburg, vice-president; C. Griffith, Johnstown, second vice-president; H. E. Bradley, Philadelphia, secretary; C. E. Wilson, Philadelphia, treasurer. The executive committee is as follows: B. F. Meyers, C. W. Kline, C. E. Wilson, J. G. Splane, R. E. Umbel, A. D. Barnard, E. D. Schade, W. B. Trask, and G. B. Rudy.

NEW COMPANY NOTES.

RIVERSIDE, CAL.—The Home Telephone Company has been granted a franchise to construct and operate a telephone line between Riverside and north county limits. The company is already laying the underground conduit system in Riverside for its local exchange.

COCOA, FLA.—The Brevard County Telephone Company has been organized with a capital stock of $5,000 to build and operate a telephone line from Cocoa and Eau Gallie; from Cocoa to Titusville, and to Courtnay at Merritt Island and south to Tropic. The incorporators are: H. S. Williams, Joseph Paxton, G. S. Hardee, S. S. Jones and R. W. Andrews.

ESTHERVILLE, IA.—The Emmett County Telephone Company has been organized and at the next election the company will put its proposition for a franchise before the voters of the city. The company is composed of local business men and intends to construct a local telephone system with numberless lines running into the country.

RAYMOND, ME.—The Raymond and Webbs Mills Telephone Company, of Raymond, has been incorporated with a capital stock of $10,000. The officers are: F. W. Plummer, president, and G. H. Hall, treasurer, both of Raymond.

BALTIMORE, MD.—The Holmes Electric Protective Company has been incorporated with a capital stock of $100,000 to conduct a telephone business. The incorporators are: Edward T. Holmes and Robert A. C. Smith, of New York; Henry P. Wilcox, H. K. McCabe and Charles T. Crane, of Baltimore.

PRINCESS ANNE, ME.—The Manoker Telephone Company has been incorporated with a capital stock of $5,000 by R. R. Hoyt, A. B. Fitzgerald, J. P. Muir, W. L. Muir, I. T. Parks, and G. W. Broyman.

LINCOLN, NEB.—The Central Nebraska Toll Line Company has been incorporated with a capital stock of $100,000. The officers are: Commander N. Beaver, president; Herman Behling, vice-president; C. H. Kolling, treasurer, and J. M. Bell, secretary.

KERNERSVILLE, N. C.—The Kernersville Telephone Company has been incorporated ith a capital stock of $5,000 by W. C. Linville, G. V. Fulp, M. V. Fulp and A. N. Linville, of Kernersville, and F. W. Lubert, of Waterbury, Conn.

CASTLETON CORNERS, S. I., N. Y.—The Castleton Corners Telephone Company has been organized here with the following officers: Maurice H. Gescheidt, president and general manager; Charles C. Wickert, secretary and treasurer; Charles C. Schmidt, chief engineer.

STERLING, N. Y.—The Sterling Telephone Company has been incorporated with a capital stock of $960.

RICE, O.—Farmers in this vicinity held a meeting recently for the purpose of organizing an Independent telephone company to construct and operate a rural and local telephone system. The organization will be completed in the near future.

BUTLER, PA.—The People's Telephone Company has been reorganized with a capital stock of $50,000. The officers are: John Younkins, president; M. Henshaw, secretary; T. Shuffin, treasurer. The directors are the officers and John V. Ritts and A. L. Rieber.

HARRISBURG, PA.—The Sullivan County Telephone Company has been incorporated here with a capital stock of $5,000 in 200 shares at $25 each. The directors are: Ulysses Bird and J. E. Bird, of Forksville; Fred Newell, George Streby and Peter J. Yonkin, of Dushore; George W. Lambert, of Overton, and Olan J. Williams, of Shunk. The company will erect and operate lines in Sullivan, Bradford, Wyoming and Lycoming countries, with headquarters at Dushore. The points to be connected are: Canton, Bradford County; Forksville, Hillsgrove, Dushore, Ricketts and Laporte, Sullivan County; Towanda and Wyalusing, Tunkhannock and Williamsport. George Streby, of Dushore, is treasurer.

MANSFIELD, S. DAK.—Farmers living in the vicinity of Mansfield have organized a Farmers' Telephone Company to construct a rural telephone line from that place. The officers of the company are: John Harrington, president; George Woodford, secretary; Charles Granger, treasurer.

LONGVIEW, TEX.—The Lacey Telephone Company, of Longview, has been incorporated with a capital stock of $5,000 by J. C. Lacey, Edwin Lacey and J. E. Yates, of Longview, and Jasper Collins, of Carthage.

COMBINATIONS.

IMPERIAL, CAL.—W. F. Holt has sold his telephone system at this place to the Arizona Consolidated Telephone & Telegraph Company for $15,000.

INDEPENDENCE, MO.—J. S. Haley, of Independence, has sold the telephone exchange at Warrensburg and Knobnoster and the connecting toll lines to the Kinloch Telephone Company, of St. Louis, for $65,000.

KANSAS CITY, MO.—The stock and lines of the Western Independent Telephone Co. have been transferred to the Kansas City Home Telephone Co. This is merely a consolidation of the working parts of the outside lines with the business of the Home Company, for the two companies were owned and operated together prior to the consolidation. The Western Independent Telephone Co. was organized to construct and operate toll lines throughout the West, connecting the various Independent exchanges with each other and Kansas City.

TILTON, N. H.—The Citizens' Telephone Company will construct a line to Northfield Center and from that place to Canterbury, connecting with the Canterbury line.

TABLE ROCK, NEB.—W. A. Conklin and others have purchased the telephone lines owned by W. C. Felliss, Ben Heer, the State Bank and G. E. Decker.

MOUSTON, WIS.—The Mouston Electric Light and Power Company and the Mouston Telephone Company have been sold to a party of business men of this city. The name has been changed to the Mouston Electric Service Company. The officers are: P. D. Curran, president; A. Rasig, secretary; William Case, vice-president; S. Bassford, treasurer, and G. J. Thew, electrician.

MISCELLANEOUS.

CHICAGO, ILL.—As rapidly as the change can be brought about, the management of the Burlington has decided to substitute the telephone for the telegraph in dispatching and operating both passenger and freight trains.

FALL CREEK, ILL.—The headquarters of the Adams-Pike Counties and Hannibal Telephone Company is at Fall Creek, Ill., instead of Quincy, as stated in a recent issue.

PEORIA, ILL.—The Interstate Independent Telephone and Telegraph Company will construct a new exchange building to cost $30,000. The building will be three stories in height and the telephone company will require most of the space to house its equipment properly. The basement will be used as a storeroom, to which purpose also the 71 feet in the rear of the first floor will be devoted. The second floor will contain the cable-room and power plant, the wire chief's office, in which testing machines are installed, a lunchroom for the operators, and the local offices of the company. The third floor will be entirely given over to the accommodation of a switchboard.

WABASH, IND.—The city officials have brought suit to enforce the removal of the poles and wires of the Central Union Telephone Company. The old franchise of the company expired a year ago and the new franchise offered was declined by the company. The city holds that a new franchise is necessary to continue business and proposes to remove the company's property from the streets.

BUFFALO LAKE, MINN.—The Stewart Electric Telephone Company's rural line running north from Buffalo Lake was considerably damaged by the recent cyclone. Many of the poles were lifted from the holes and one telephone was destroyed in a residence.

Digitized by Google

ERSKINE, MINN.—In a recent fire in this city the telephone exchange was totally destroyed.

HUTCHINSON, MINN.—The Hutchinson Telephone Crew were camped for supper when struck by the cyclone, which passed through this section of the country. Their wagon, tents and other paraphernalia were demolished and the men were covered with mud and badly pounded. The cook was found under the stove and other cooking utensils. Amount of damage was about $400 on the rural lines. The Central Minnesota had three miles of lines torn down between Hutchinson and Glencoe.

MANKATO, MINN.—The Citizens' Telephone Company, of Mankato, started six years ago with 250 subscribers and at present has 800 subscribers, 125 miles of toll lines and 125 miles of rural lines and connections with a dozen farmer lines. Have built a trunk copper line from Worthington to the Twin Cities; this line will connect at Worthington with the Sioux Falls line, now being erected to Yankton, Mitchell and Sioux cities.

MINNEAPOLIS, MINN.—The telephone companies in the Twin Cities were hard hit by the cyclone that passed through that section recently. Miles of poles and lines were blown down in the city limits of both St. Paul and Minneapolis and thousands of "drop" lines are out of commission.

RICHMOND, MO.—Parties interested in the organization of the Mutual Telephone Company, of Ray County, Mo., held a meeting recently at Richmond and decided to organize on October 1st.

ST. JOSEPH, MO.—J. S. Newell, president of the Citizens' Telephone Company, and Jesse S. Funston, president of the Funston Telephone Company, both deny the report that their companies have been absorbed by the Gould system. The Citizens' company is a local Independent company and the Funston company is building a line to Chillicothe and thence to Kansas City and from Hamilton, Mo., to points in Iowa.

EDGERLY, N. D.—C. J. Sturgeon has put in a 150 drop switchboard in the local telephone exchange.

HARRISBURG, PA.—Highway Commissioner J. Austin Brandt has served notice to companies maintaining poles upon the streets of Harrisburg that they must be painted, lettered and numbered within sixty days. This action is taken because it is frequently difficult to locate the owner of a pole when it is desired for any cause to move it. The name or initials of the company, together with the number of the pole, must now be placed on each. The timbers must be painted from ground to tip. Telephone companies affected are the United Telephone and Telegraph Company and the Pennsylvania Telephone Company (Bell).

HOMESTEAD, PA.—The P. A. Telephone Company has installed a duplicate system in conjunction with its exchange in this city whereby it is possible to signal a party in the usual manner if the automatic fails to operate.

NEW BOSTON, TEX.—The New Boston Telephone Company has advertised its exchange for sale.

UNDERGROUND.

DIXON, ILL.—The Lee County Telephone Company is laying an underground conduit system in this city.

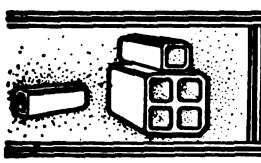
PERSONAL.

M. W. MITCHELL, of Wilkesbarre, Pa., has been appointed manager of the Cleburne, Tex., telephone exchange, vice Vanwormer, resigned. He is now in charge.

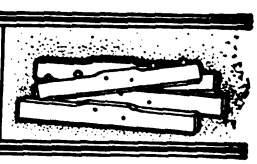
J. W. ORCHARD, of Nashville, has been appointed manager of the East Tennessee Telephone Company's exchange at Morristown.

J. G. SIGLER has accepted the position of manager of the Kinloch Telephone Company's exchange at St. Charles, Mo. The former manager, George P. Player, who has been appointed wire chief of the company's long-distance service, will be located in St. Louis.

E. C. STARKS has resigned the management of the Wood County Telephone Company at Grand Rapids Mich., to take charge of the Northern Rural Telephone Company's system at Spencer, Wis.



New Construction in the Field



DECATUR, ALA.—The Morgan County Telephone Company has built a line to Trinity and will extend it on to Memphis, where it will have connections with the principal cities east of the Mississippi River.

ETNA, CAL.—An assessment of large proportions has been levied on the stock of the Siskiyou Telephone Company for the purpose of putting the line in better condition. A metallic circuit will be put in from Yreka through Scott Valley to Salmon River and back.

SUMMERLAND, CAL.—The Home Telephone Company is pushing the construction work of its system so as to get it in service as soon as possible.

ALTON, ILL.—H. G. Bassett has secured the contract to build two miles of the Fosterburg-Upper Alton telephone line into the Burg.

BUFFALO HART, ILL.—The Williamsville Telephone Company is busy constructing their line from here to Dawson.

CHICAGO, ILL.—The Lake Shore & New York Central recently completed its telephone system from Chicago to New York.

SPRINGFIELD, ILL.—The Pana and Christian County Telephone Company is erecting a new lead cable in connection with its system.

SOUTH WHITLEY, IND.—The Farmers' Mutual Telephone Company is moving its exchange to larger quarters and will install about 1,500 feet of conduit.

CRESTON, IA.—The Mutual Telephone Company has extended its line to Macksburg.

MILL CREEK, KY.—The Elmwood Place Business Men's Club contemplates constructing an Independent telephone company to furnish local telephone service to Mill Creek business men. Elmwood business men have volunteered to back the new concern if the contracts for the village fire-alarm service can be secured as a source of revenue. Several hundred subscribers are promised.

NEW IBERIA, LA.—The People's Independent Telephone Company has recently reconstructed its lines in this city and is increasing its switchboard capacity on account of increasing demand for telephone service both in the city and country. The Independent business is increasing in Louisiana.

SHERMAN, ME.—Milliken, Wren & Porter are building a telephone line from Sherman to Island Falls. They claim they have over 100 subscribers and many new ones expected. They expect to build to Smyrna Mills this fall and in the spring to Kingman.

COTTONWOOD, MINN.—The Home Telephone Company has secured a sufficient number of patrons to warrant the construction of three rural telephone lines.

GLENCOE, MINN.—The Minnesota Central Telephone Company is rebuilding its long-distance line from Glencoe to Hutchinson and from Glencoe to Renville. It is also stringing a copper metallic circuit over the entire line, making three metallic circuits between Glencoe and Renville.

HENNING, MINN.—The telephone line is extending its copper line from here to Deer Creek.

DASSEL, MINN.—The Dassel & Collinwood Telephone Company will construct a system in Central Collinwood.

OWATONNA, MINN.—The lines of the Merton Rural Telephone Company which were completed recently are about twenty-five miles in length and extend through Owatonna, Merton, Medford and Clinton Falls townships.

THIEF RIVER FALLS, MINN.—The line to Scotland and Germantown will soon be completed.

KANSAS CITY, MO.—The Home will at once begin the extension of its long-distance lines in Nebraska and will improve its service in Kansas and Missouri. By the terms of its agreement with the Kinloch company the territory of Missouri has been divided, the northeast and southeast being apportioned to the Kinloch company and the northwest and southwest to the Home company. The Kinloch company has also agreed to keep out of Kansas. The Home company is in an excellent position to build up one of the largest Independent systems in the country.

DIXON, NEB.—A rural telephone line will be constructed from this place out into the country for the accommodation of farmers.

BINGHAMTON, N. Y.—The York State Telephone Company has recently completed its lines to Elmira after two years' hard work. The delay was caused by the opposition of property owners to right of way.

FULTON, N. Y.—The Fulton Telephone Company will install a new switchboard.

HARTWICK, N. Y.—The Hartwick Independent Telephone Company has extended its lines to Oneonta and Cooperstown via West Oneonta, Laurens, Mount Vision, South Hartwick and Fly Creek.

NEW LISBON, N. Y.—The New Lisbon Telephone Company is stringing wire from here to Edmeston and will connect with the West Winfield line, also giving communication with Burlington Flats, Exeter.

FINLEY, N. D.—The Union Telephone Company will put in a local exchange.

GREENVILLE, O.—The Greenville Home Telephone Company has nearly completed its new line to Fort Jefferson and other points in the southwestern part of the county.

KENTON, O.—The Kenton Telephone Company is planning to purchase property in this city on which it will construct a new exchange building.

TIFFIN, O.—The Tiffin Home Telephone Company has installed a new switchboard of 1,200 lines installed with ultimate capacity of 3,000.

PINE, ORE.—The telephone line from here to Homestead will be completed in a short time.

HARRISBURG, PA.—The directors of the United Telephone and Telegraph Company at a meeting held here recently made an appropriation for rebuilding the plant at Littlestown and a line from Gettysburg to Littlestown.

EL PASO, TEX.—The Colorado Telephone Company now operates long-distance lines in the Las Vegas and it is announced that this company will extend its line as far south as Socorro touching Santa Fe, Albuquerque, Cerillos, Belen and other points. The company will also extend its line to Las Cruces and get connection with El Paso.

MEADVILLE, PA.—The Meadville Telephone Company has closed a contract to build a line between Meadville and Cochranton. When this line is completed it will give the Meadville company a through copper circuit to Pittsburg and will also give them direct connection with Franklin, Oil City and Titusville. The contract calls for the completion of the line in sixty days.

OGDEN, UTAH.—The Utah Independent Telephone Company will connect Ogden and Salt Lake City. It has already put up its switchboard.

SUFFOLK, VA.—The Nansemond Telephone Company is rapidly extending its system and building toll lines into surrounding countries.

BRIDGEPORRT, W. VA.—The Belmont Telephone Company will establish an exchange and will install a local system of telephones in Bethesda at once. Lines will be built into the surrounding territory.

FAYETTEVILLE, W. VA.—The Wyoming Development and Telephone Company has just completed a telephone line from Oceana, the county seat of Wyoming, to Hallsville, in this county, a distance of twenty-two miles. This line touches Bailesville and Toney's Fork, and at Hallsville connects with the Welch Williamson Telephone Company's lines, enabling the people throughout the entire territory traversed by the latter company and the Bluefield Telephone Company to talk to Oceana and intermediate points.

ANTIGO, WIS.—The work on the telephone line is progressing rapidly.

APPLETON, WIS.—The Fox River Valley Telephone Company has completed its new line to Hortonville. It is the intention of the company to run other lines through the country as fast as they can be constructed.

LA CROSSE, WIS.—The line of the Tri-State Telephone Company has reached La Crosse and connections have been made, thus giving La Crosse communication over it to Minneapolis and all points in the northwest. The large cable across the Mississippi River has been finished and the line is practically done.

WEBLAKE, WIS.—A telephone line will be constructed from Swiss to Spooner by way of Weblake.

PRETORIA, TRANSVAAL, S. A.—It is rumored that $65,000 will be expended in the installation of an up-to-date telephone system in the city of Pretoria, Transvaal, South Africa.

Digitized by Google

TRADE NOTES.

THE F. BISSELL COMPANY, of Toledo, Ohio, has recently issued several circulars and price lists of the various pieces of apparatus it manufactures.

THE MONARCH TELEPHONE MFG. CO., of Chicago, Ill., reports unusual activity in all branches of its establishment. Several large orders have recently been filled for complete equipment.

THE VOUGHT-BERGER COMPANY, of La Crosse, Wis., wishes to call the attention of the exchange manager to the twenty-four exclusive advantages claimed for the Pendant telephone. To those interested the company will be pleased to enumerate them.

THE INTERNATIONAL TELEPHONE MFG. CO., of Chicago, has recently secured a large order for switchboard equipment to be used in extensions to a telephone system in San Paulo, Brazil, consisting of a 4,000-line capacity 1500 equipped self-restoring drop switchboard.

THE BAIRD MANUFACTURING CO., of Chicago, reports that it has received two large orders from old customers for pay-station apparatus which not only proves that its machines are giving complete satisfaction but that they are proving a most profitable feature of their customers' business.

THE AMERICAN ELECTRIC TELEPHONE CO., of Chicago, reports among recent shipments of switchboards the following equipments: Albion, Neb., 100-line switchboard; Osage, Ia., 500-line switchboard; Louisville, Neb., one 100-line switchboard; Plattsburg, Mo., 100-line switchboard; Hopkins, Mo., 200-line switchboard.

S. H. COUCH CO., of Boston, states in a neat blotter just issued: "We are now prepared to furnish our No. 12 telephone and other common return intercommunicating telephones wired for our central battery system B12. This system is non-interfering in that all of the circuits may be in use simultaneously and parties on one circuit not be disturbed by the conversation of parties on another circuit."

THE W. G. NAGEL ELECTRIC COMPANY is exploiting the Polk Safety Cut-in Knob. By the use of this porcelain insulator telephone cmpanies are not compelled to tie in their drop wires where duplex is used. It not only secures quickly, but permanently. The wires can be run in from any direction with absolute safety. It is believed that telephone companies will find this insulator to be a time-saver as well as a money-saver.

HUBBARD AND CO., of Pittsburg, Pa., reports that its factory, which was recently destroyed by fire, has been entirely rebuilt and much enlarged. All the most up-to-date tools and apparatus have been installed, which will add toward securing the best results in manufacture of the articles that are made. This company is one of the largest in this country or in the world for the manufacture of shovels and similar tools. The company will be pleased to furnish catalogues and prices upon request.

THE ELECTRIC STORAGE BATTERY COMPANY, of Philadelphia, has issued a very neat memorandum book relative to storage batteries. The book is handsomely bound in celluloid and of such a shape as to be conveniently carried in one's coat pocket. Characteristics of a good storage cell forms the introduction and includes a fund of information. The application of chloride accumulators in railway power plants is next dealt with and includes illustrations of curves gained from actual practice. Chloride accumulators for all classes of work are thoroughly described, together with hints upon their proper location and care. The book concludes with a number of valuable tables covering a large range of subjects, all of which are vitally important to engineers. This booklet will be mailed to all engineers desiring a copy.

FRANK B. COOK, of Chicago, Ill., has recently had three decisions rendered in his favor by the United States Patent Office in interference case No. 23,636, Cook vs. Kaisling, relative to a self-soldering heat coil. July 25th, 1904, the department denied Kaisling's motion on leave to amend his preliminary statement. August 11th, 1904, the department denied Kaisling's motion for rehearing on leave to amend his preliminary statement. August 12th, 1904, decision was rendered denying Kaisling's motion to dissolve the interference on the ground that Cook had no right to make the claim, the examiner deciding that Cook alone was entitled to the claim in interference. Limit of appeal expired September 1st, and as no appeal was taken, the subject matter defined in the issue remains in Cook patent and must be erased from Kaisling's. Mr. Cook's success in patent suits seems phenomenal.

THE WILLIAMS TELEPHONE AND SUPPLY CO., of Cleveland, Ohio, has brought out a new style of switch hook which has genuine platinum contacts and is proof against grounding or short circuiting. This hook has four contacts and no pivot connections, four springs being used which are readily connnecting to the talking and ringing circuits. Neither the lifting spring hinged joint or the frame is used as a part of the electric circuit, thereby eliminating all possibility of loose contacts, which in that position would be difficult to locate. The platinum contacts furnish a positive electric contact in all climates and under all conditions of moisture and temperature. The springs are so adjusted that the hook is perfectly balanced. The hook is self-contained and can be taken out for any purpose without disturbing the other parts of the telephone. The lifting spring is of tempered steel, which is always uniform in its tension. The general design has been to supply the best possible hook and this the company believes has been done. A booklet has been prepared dealing with rural line construction and will be mailed upon request.

WANTED

Advertisements under this head, 25 cents for 25 words or less for each insertion. Prepaid.

WANTED you to know that I can locate your cable troubles. Charges moderate. Address C. E. NICHOLAS, Columbus, Ohio. 226

WANTED to correspond with investor for the advancement of Independent telephone interests in Eastern Iowa. Good territory; small capital. Address Box 250, AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 250

WANTED—Second-hand generators and ringers in good condition; give make, general condition and price asked. Address Box 223, AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 223

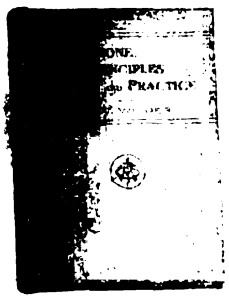
THE NEW TELEPHONE BOOK



By G. W. WILDER, Ph.D.,
Professor in Telephony
Armour Institute of Technology

This book is strictly up to date and complete in every respect. It deals with all of the ins and outs of telephone apparatus. Profusely illustrated with drawings and half tones. Instruments, switchboard and cord circuits with detailed descriptions, enable anyone to thoroughly understand all the problems met with in telephone practice.

CONTENTS

CHAPTER.		CHAPTER.	
I.	Magnetic Action.	XVI.	Instruments and Instrument Circuits.
II.	The Centimeter-Gram-Second System.	XVII.	Party Lines.
III.	The Electric Current and Magnetism.	XVIII.	Exchange Systems.
IV.	The Solenoid.	XIX.	Switchboard Circuits.
V.	The Production of an Electrical Pressure.	XX.	Switchboard Details.
VI.	Sound.	XXI.	Complete Switchboards.
VII.	Early Forms of Telephony	XXII.	Capacity.
VIII.	The Telephone Receiver.	XXIII.	Common Battery Systems
IX.	The Transmitter.	XXIV.	Selective Party Lines.
X.	Induction.	XXV.	Location of Exchanges and Pole Lines.
XI.	The Induction Coil.	XXVI.	Poles.
XII.	The Magneto Generator.	XXVII.	Wire.
XIII.	Ringers.	XXVIII.	Construction of a Wire Plant.
XIV.	The Generator Shunt.	XXIX.	Cables.
XV.	The Hookswitch.	XXX.	Lightning Protection.
		XXXI.	Line Disturbances.
		XXXII.	Electrical Testing.

The 1900 Dry Battery

THE most needed quality is reliability. No one wants a battery that will respond all right for a week or ten days then "suddenly go out of business." Another requirement is that it shall continue "strong" during its life. These two requirements besides many others are characteristics of

1900 BATTERIES

We guarantee them not to freeze, leak or break; we warrant them to work with a strong, steady current during their life (anywhere from six to eighteen months).

They are compact, always ready. They are better than wet batteries—no slop, no repairs, no breakage. Any one can replace a worn out one at a moment's notice. They can be carried anywhere—always ready for instant use.

Write us for our Complete List of Batteries and Telephone Supplies

Bituminized Fiber Conduit
For Underground Construction

Combines the **good features** of other conduits. **Eliminates** the **bad features** existing in many kinds. **Has valuable features** not found in any other ducts. :: ::
Made in 7-foot lengths with male and female joints, making construction very rapid and simple, with consequent low cost. :: :: ::
Alignment is perfect and permanent without tedious care and skill required in laying of butt-joint conduits. Users are astonished by the ease and rapidity with which cables can be drawn in, and this without the slightest scratching or injury to the lead covering thereof.
Made in sizes from 1-inch to 10-inch diameter. ::
Bends of any radius and any angle. :: ::
Write us for further information and prices, stating sizes and quantities required. :: :: ::

American Telephone Practice
By KEMPSTER B. MILLER, M. E.

518 large pages, profusely illustrated with 380 diagrams and cuts of apparatus **$3.00**

A book for the telephone man. It is an encyclopedia of useful information concerning telephony.
It gives complete specifications, enabling you to intelligently order apparatus from manufacturers, and to properly supervise the installation of an exchange, large or small.
It describes in simple language the theory and practice of modern telephony, including circuits, mechanical construction and operation of telephones and switchboards.
A complete description is given of storage batteries, their care and maintenance; of aerial and underground line construction, and, in fact, all the important matters which telephone men need to know.

THE AMERICAN TELEPHONE JOURNAL

Not Only As Good— But Better

That's what our aim for The American Telephone Journal is for the future. This is in line with our past policy.

That our subscribers believe this is shown by the following letter:

> "Enclosed find check for $2.00. Please renew my subscription for two years in advance. I don't want your paper to stop coming, so I send some in advance."
>
> J. A. MOORE,
> Ansley, Neb.

With such hearty co-operation on the part of our subscribers, it is easily seen how we can carry out our policy of betterment.

Our Selective Central Relay

used on **generator call party lines** at "**central**" does not respond to alternating ringing current.

Relay responds promptly to very weak **direct** current, either pulsating or continuous, **negative** or **positive** as desired.

Relay is simple, only three moving parts.

Relay is adjusted by a hanging weight, similar to the movement of a clock pendulum.

Relay responds to a very small fraction of the current necessary to operate a **bell** or **drop** or ***any* iron core** signal receiving apparatus of similar nature.

Our system operates on Single Wire Ground Lines, Straight Metallic or "Divided Circuit" Metallic Lines.

You can use the **telephones** and **switchboards** you now have.

New telephones for our sytem are supplied by a number of **telephone manufacturers.**

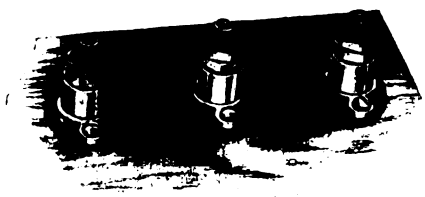
The VERY BEST Telephone

Regardless of Price, Is What Our Customers Demand

PERFECT PARTS FOR THE PERFECT TELEPHONE

SIMPLE

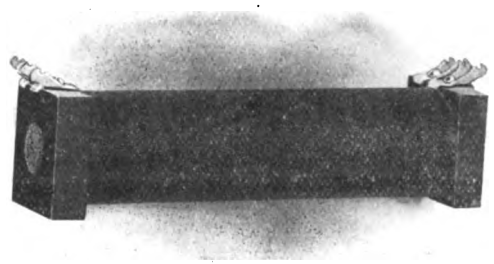


EFFICIENT

Our No. 20 -- ARRESTOR

Machine-made binding posts fitted with two hexagon nuts. Carbons are of good size, thus offering a good discharge surface. They are held under constant pressure between springs, but can be readily removed.

CORRECTLY DESIGNED

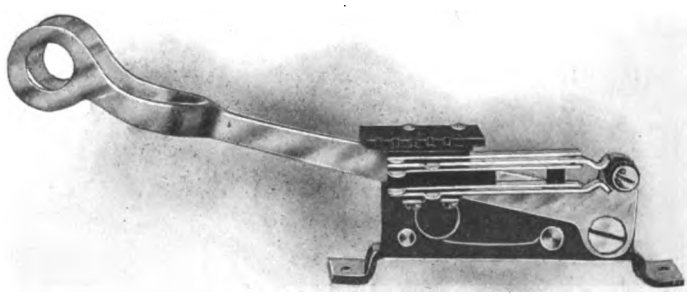


UNIFORM IN RESULTS

Our No. 20-A -- INDUCTION COIL

This coil is used in all our Generator Call telephones. It is manufactured by automatic machinery, thus producing a coil that will give absolutely uniform results. The heads are made of seasoned maple, and are provided with convenient terminal clips. The windings consist of the best grade of copper wire silk insulated.

SELF-CONTAINED



POSITIVE IN ACTION

No. 5 -- HOOKSWITCH

This type of hookswitch operates so satisfactorily that we use it in all of our telephones, simply modifying the mounting plate or frame so it will fit into different styles of telephones.

All this apparatus is fully described in Bulletin No. 11-B

Lightning is a menace to the life of anyone using a telephone if it is not properly protected. The

Andrae Lightning Arrester

has long been known as the most simple and reliable.

Anarae Telephone Cords

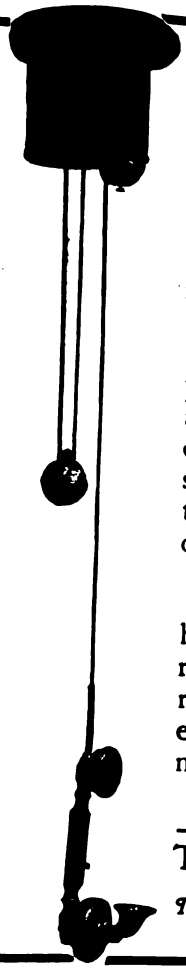
are of the highest grade, not only presenting fine external appearance, but possessing exceptional lasting qualities.

Remember the "Andrae System," which gives you the best telephones, switchboards and appliances at low cost.

Write to-day for particulars.

Julius Andrae & Sons Co.,

945 West Water Street, . MILWAUKEE, WIS.



"A place for everything, and everything in its place"

A very good motto—as far as it goes.

In the very nature of things some places are inconvenient.

The wall phone has *its* place, necessarily—more's the pity, we sometimes think.

The desk phone might have a place, but usually has a dozen—and often isn't in any of them, or else is obstructed, or obstructs something. It is less disturbing than the first, however, and requires less awkward attitudes.

The Pendent Telephone

has one place—in disuse, the readiest conceivable, and is always right there, at the crook of the elbow, in the way of nothing, and nothing in its way.

ERICSSON RURAL LINE SYSTEM

A very simple system for all Farmer and Rural Lines, by which the subscriber calls at will any other subscriber on the same line without calling central: calls central at will without calling any other subscriber. This system pleases the subscribers, saves much time to the operator, and makes the service entirely satisfactory. Ask for particulars. You will want it. We manufacture a great variety of Telephones, Switch-Boards and Specialties. Ask for catalogue M and our laughter-provoking novelty.

Replying to yours of recent date, we are more than pleased with your telephones. We have about 75 in use now, and will add more soon. These are used on the same system with two other makes, and are we believe superior to any. At one time, before we connected our rural lines with the switchboards, we had 37 phones on one line, and beyond the confusion of calls, they gave good satisfaction. At present we have 29 phones on one rural line, and they all ring clear and true. I don't know what more could be expected. Not only are we pleased with the telephones, but we are pleased with the courteous treatment your house has accorded us, and hope our business relations may be long continued.

Yours very truly,

Robert Good

TELEPHONE EXCHANGE ENGINEERING

ARTICLE XX.—CONDENSERS (CONTINUED).

By Ray H. Manson, Albion D. T. Libby and Charles A. Simpson.

THERE is no definite standard as to the shape, size and capacity of a telephone condenser, though now a two microfarad condenser, which will go into a space 9x5x¾ inches, is largely used. With the newer designs of telephone apparatus the condenser is constructed with a capacity to fit the electrical conditions of the circuit and of a size and shape to go into the space allotted. The result is higher efficiency circuits and more compact and neater apparatus.

Nearly all telephone condensers are now made of the rolled type, in which the two tinfoil plates and paper separators are continuous sheets. Enough condensers are easily constructed, and when made of adequate material and with proper care, will give practically no trouble.

Telephone Condenser Construction: The construction of a roll type, two microfarad condenser is as follows:

An iron plate, made as shown in Fig. 86, is used as a permanent core on which to wind the condenser material. The core is placed in a special winding machine so that it can be revolved about its long axis by a crank handle. A counter is arranged to keep record of the revolutions of the core and thereby give the operator the exact amount of material used. The winding machine contains four spools of rice paper 8.25 inches wide and 0.00125 of an inch thick, and two spools of condenser tinfoil 7.25 inches wide and 0.0005 of an inch thick. The material from each of these spools is fed through retarding devices, which always keep the paper and foil at an even tension, giving a smooth winding machine and from each other and are connected in series with a bell and battery, as shown in Fig. 87. Now, if the two tinfoil surfaces of the condenser roll become crossed, while winding, it will be immediately made apparent by the ringing of the bell.

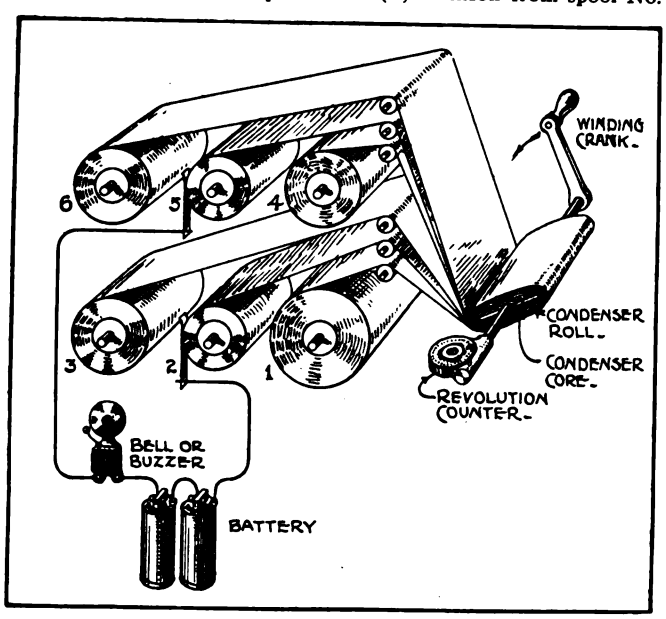

Fig. 87. Machine for Winding Roll Type Condensers. The Frame of the Machine is Omitted to Make the Drawing More Easily Understood.

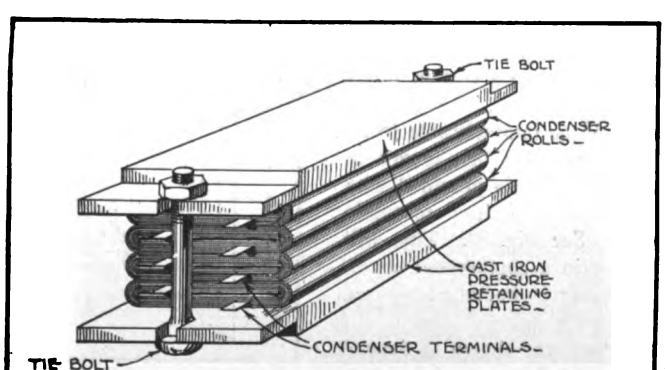

Fig. 88. Clamping Plates for Removing Roll Type Condensers from the Press while Under Pressure.

Winding: The operations of winding a condenser roll are as follows:

(a) Paper from spool No. 1 is started on the iron condenser core and the crank revolved four complete turns. This serves as an insulation from the metal.

(b) Tinfoil from spool No. 2 is started.

(c(Paper from spool No. 3 is also started, but is pulled out so as to overlap the foil No. 2 about one-half of an inch.

(d) The crank is revolved one-half turn so as to catch and hold No. 2 foil and No. 3 paper in the roll.

(e) Paper from spool No. 4 is started.

(f) Tinfoil from spool No. 5 is started, but is only pulled out to within one-half an inch of the length of the paper from spool No. 4.

(g) Paper from spool No. 6 is also started and pulled out to the same length as No. 4 paper.

(h) The elements *e*, *f* and *g* are now started into the roll and the crank revolved about sixteen and one-half complete turns, making twenty-one turns on the counter.

(i) A sheet brass terminal, Fig. 86, is inserted between paper No. 1 and foil No. 2, so that its small or connecting end projects at the top end of the condenser roll.

(j) The crank is revolved one-half turn so as to bring the other side of the condenser roll uppermost.

(k) A second sheet brass terminal, Fig. 86, is inserted between paper No. 4 and foil No. 5 in a similar manner to the first terminal. This brings the terminals on opposite sides of the iron core, the projecting ends being separated about two inches. Placing the terminals about half-way out on the winding gives a safer insulation after the rolls are compressed.

(l) The crank is now revolved twenty-four and one-half complete turns, making forty-one turns of foil or forty-five turns of the counter.

(m) Paper No. 4, foil No. 5 and paper No. 6 are now cut with

Digitized by Google

a large pair of shears, about two inches from the winding roll.

(n) Foil No. 2 and paper No. 3 are also cut together, in the same manner, but about three inches from the winding roll.

(o) The crank is revolved five more complete turns, winding

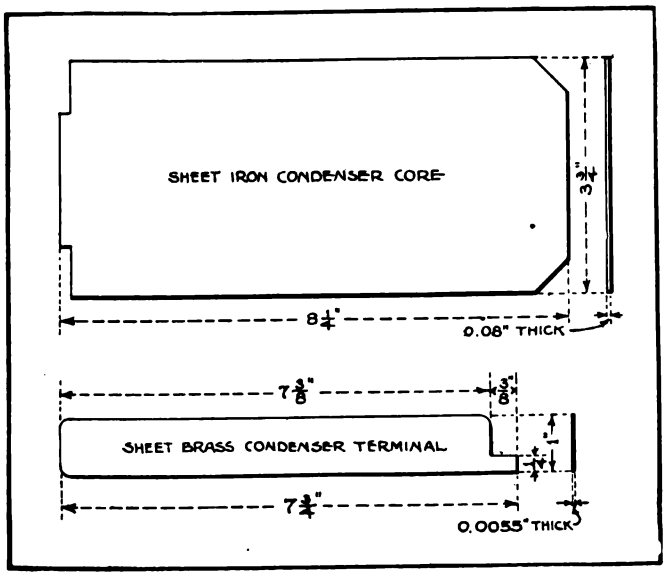

Fig. 86. Core for a Two Microfarad Roll Type Condenser, and one of the Two Terminals of a Two Microfarad Roll Type Condenser.

paper No. 1 over all, for an outside insulation. This makes a total of fifty turns of the counter.

(p) Paper No. 1 is now cut and its roll-end pasted down with Photo Library Paste (starch paste).

From this description of the winding of a condenser it will be seen that two sheets of paper separate one sheet of tinfoil from the other and for their entire length. This is done to give a higher insulation with a certain thickness of material and to prevent any conducting particle, which might lodge between the sheets, when winding the condenser, from easily puncturing the insulation and crossing the plates. Also any structural defect in one paper will be covered by the other paper.

In the construction under consideration the core constitutes a part of the finished condenser, but in the majority of makes, a temporary form is used to wind the condensers over, it being removed when the winding is taken from the machine.

Baking: The windings are now carefully baked for several hours in a special oven to drive out all of the moisture from the paper and from between the layers.

Boiling: Upon removing from the oven, the windings are placed in vats of boiling paraffine and allowed to remain until all of the air is driven out. Paraffine for condenser construction should have a high melting point and should be free from all acids or other impurities which would tend to lessen the insulation resistance.

Pressing: The windings are taken from the paraffine vats, placed between hot metal plates and squeezed to a certain thickness, in which position they are allowed to cool. As it takes several hours to do this cooling—it would be impracticable to allow the condensers to remain in the press for this length of time. So the hot plates, previously mentioned, are provided with slots for end bolts, which can be screwed in position to retain the pressure given by the large press. See Fig. 88. This will allow the condenser rolls to be removed in a compressed condition and set away to cool while the press is immediately used for more condensers.

The electrostatic capacity of a condenser was shown to depend on the thickness of the dielectric material between the plates, provided the plates were in contact with this material. It is for this reason that the paraffined condenser roll is compressed. The previously described condenser winding is designed to give a capacity of two microfarads when given the proper pressure. If it is given less pressure, the condenser will have a greater thickness of dielectric material and the capacity will be correspondingly less. With a greater pressure, the dielectric material is made thinner and this condenser roll can be made to give a capacity of over ten microfarads. In this connection, the question often presents itself: Why not use less material in the roll and use greater pressure to give the proper capacity? The reason is obvious, for when the thickness of the insulating medium is decreased the condenser is not only subject to greater leakage, but is more liable to break down under the electrical pressure to which it might be subjected to in practice. For some circuits, however, when the condenser is protected by a permanent shunt of low resistance, or when there is only a small electrical pressure at the condenser terminals at all times, it is permissible to use a condenser with its capacity obtained by greater pressure. This of course gives a much smaller roll and the finished condenser can be put in a much smaller space. For example, a one-half microfarad condenser can be made to occupy a space $2\frac{5}{16} \times 1\frac{3}{16} \times \frac{3}{4}$ inches. A condenser of this size will easily go into the base of a desk stand.

When the condenser rolls are compressed, several are placed between one set of hot metal plates, as shown in Fig. 88, so as to be squeezed together. The press forces these plates together until they meet a separation gauge; the length of which is equivalent to the desired capacity of the condenser. In the case of the two microfarad condenser under consideration, the thickness of one compressed condenser is about 0.49 of an inch.

In pressing the condensers the hot retaining plates keep the paraffine from hardening until the proper pressure is obtained. After the condensers are thoroughly cool the tie bolts can be loosened and the rolls removed without fear of relaxing their permanent set.

At this stage of construction, some manufacturers give the condensers a preliminary test for capacity so as to reject all rolls not coming up to standard, before doing more work on them.

Casing: Unprotected condenser rolls can be used commercially, but are liable to injury, especially when kept in stock and subjected to handling. A metal covering, in the form of a sealed tin box with projecting terminals, gives proper protection and facilitates mounting in telephone equipment.

The two-piece condenser case, shown in Fig. 89, is of the

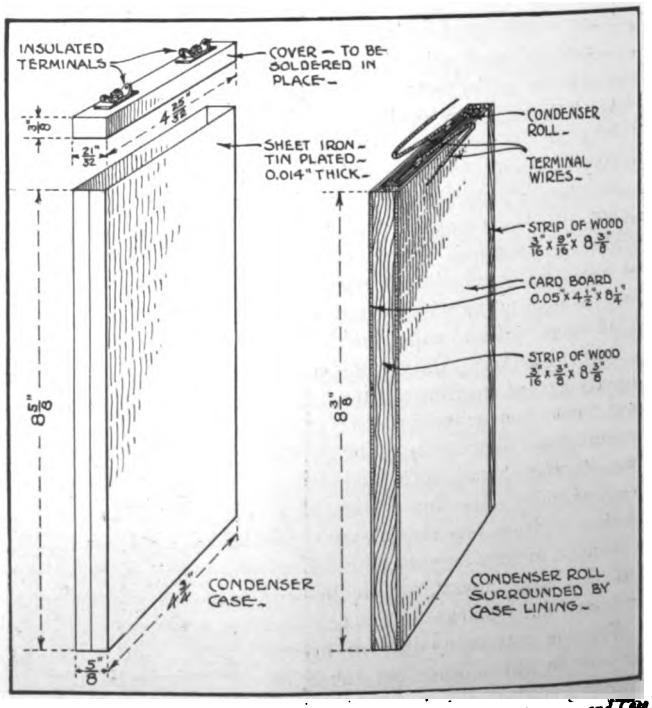

Fig. 89. Metal Case Used as a Housing for Roll Type Condensers, and Case Lining Surrounding Condenser Roll.

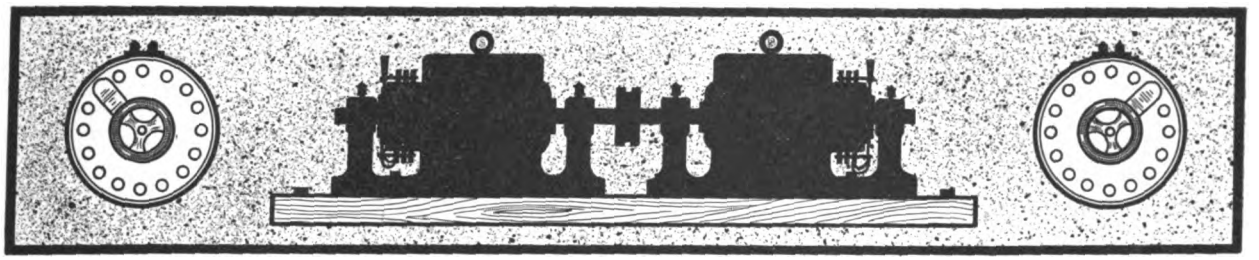
proper dimensions to hold the previously described two microfarads capacity roll. Fig. 89 also shows the lining materials of this case placed about the condenser roll in their assembled positions.

Any tendency of the metal cases to bulge at the sides is pre-

Digitized by Google

vented by placing the condensers in a press, a quantity at a time, and while squeezed to their normal dimensions, the remaining air spaces in each are filled with melted paraffine. It is obvious that this paraffine could not be poured very hot and in large quantities without loosening up the rolls and damaging the capacities of the condensers, so it is taken just above the melting point. The terminals of the condenser rolls are now connected to the insulated case terminals by short pieces of covered wire, after which the case covers are soldered in place. The condenser is now complete, excepting a finish of japan or enamel, which is applied to the surface of the case by dipping or otherwise.



ECONOMIC FEATURES IN MODERN TELEPHONE ENGINEERING

By Le Roy W. Stanton.

THE past quarter of a century has seen a most marvelous development in every phase of industry, and this is specially true in the art of telephony. The present unparalleled demand for telephone service indicates that the next ten years will see improvements in design of equipment and methods of construction that will eclipse the past decade. The unprecedented telephone development of the past few years has taxed the ingenuity of telephone engineers. While they have met the problems with remarkable success, there is room for even as great an improvement in the future. This is especially true in equipping city exchanges where there are a large number of subscribers. So two distinct methods of supplying service in large cities have developed. One uses a large individual office, while the other provides a number of multiple or branch offices interconnected by trunks. The single office possesses many advantages in small and medium sized cities, while in our largest cities it becomes impractical at the present state of the art to supply telephone service from one central office, and as a result, branch offices are a necessity.

In cities which develop a telephone population of 20,000 to 25,000, within a radius of four or five miles, from the telephone center an individual office, built after the most modern ideas, possesses many advantages over multiple or branch exchanges, such as more prompt and accurate service and by effecting a decided economy in operating.

Each subscriber's call, when there is only one office, is handled directly by one operator instead of being passed through two, over trunks connecting branch exchanges, thus saving time and expense and reducing the liability of error. There is also economy in other items, such as rent, taxes, light, heat and other office expense. The supervision in a single office is better, because it is under one management, instead of being scattered in a number of small exchanges. But in a single central office there is a larger investment in the wire plant, on which there is an annual fixed charge for interest and depreciation.

With the correct number of branch offices properly located, the average wire mileage per subscriber is reduced, because each office is nearer to the group of subscribers that it serves. The trunks connecting the branch offices add somewhat to the total wire mileage, but in a well designed multiple office plant, the trunk wire mileage plus the line mileage is considerably below that of the line mileage required to connect the same subscribers to one central office. However, if there are too many branch offices the total wire mileage exceeds that of the individual office, owing to the fact that the number of trunks joining the various offices increases in arithmetical progression, while the number of offices increases in direct ratio. This is clearly illustrated if we consider each subscriber's station as a branch office and join each subscriber to every other subscriber with a pair of wires, which we will consider as a trunk.

To connect four subscribers it would require six pairs of wires, to connect eight subscribers would require twenty-eight pairs, to connect sixteen would require 120, and so on. From this it will be seen that there is a limit to the number of branch offices for a city of a given size, and if this number of offices is exceeded, we not only increase the total wire mileage, but also the operating expenses and complications in trunking and decrease the efficiency of the service. In addition to the extra expense for trunks joining the various offices there is the additional expense of the trunking apparatus. This also increases as the number of exchanges increases, but the expense is offset more or less owing to the decrease in the cost of the subscriber's multiple.

The number of branch offices that was the most economical to serve a given number of subscribers a few years ago is far from the most economical number of offices for serving the same number of subscribers under modern conditions. Recent improvements in the manufacture of lead covered cables and improved methods in outside construction have very materially reduced the cost of the wire plant. This together with the most advanced ideas in central office equipment has greatly increased the capacity and reduced the first cost of large individual exchanges.

Owing to improvements in switchboard construction there is, at present, no difficulty in securing a central office equipment for handling at least 12,000 lines. In some cases switch boards having a capacity of 18,000 to 20,000 lines have been installed, but such large boards are not advisable owing to the fact that the jacks have to be made too small and the plugs having very little strength, are easily broken, there are also traffic disadvantages which prevent rapid and accurate work on the part of the operator.

Operators in making connection in the multiple develop what would be known in psychology as the sense of muscular touch, which allows the operator to make connection almost without looking. Where small jacks are used, this to a degree is lost, operators must further become familiar with the location of 20,000 jacks which is beyond their capacity. Four division boards have also been resorted to, but the inevitable complications make them impractical. A modern exchange having 12,000 answering jacks and equipped to furnish four party line service can handle 20,000 or 25,000 telephones and gives a far superior service to that

Digitized by Google

furnished a few years ago over multiple boards of 5,000 to 6,000 lines in a city. Formerly the difficulty of building large multiple boards offered a very formidable barrier to large individual exchanges; because the size of the jack prevented more than 5,000 to 6,000 from being placed in reach of one operator. Recent improvements have eliminated the third conductor and reduced the jack to two springs. This exchange, together with the improvements in mechanical design, and better workmanship has made it possible to place 12.000 lines within reach of an operator. A further result of the above improvements has been reduction in price of multiple jacks of at least two-thirds below that of the much inferior product of a few years ago.

While there have been remarkable improvements in the central office equipment, there have been also rapid strides made in bettering distribution to subscribers. Improved methods in the manufacture of telephone cable have increased their efficiency and very materially reduced their cost, so that to-day cables can be installed in underground conduits at a cost per pair of wires far below that of a few years ago and have increased in like proportion the territory served by one exchange. Four hundred pair cables are not uncommon today and in some cases six hundred pair cables have been used. A four hundred pair cable carried near the outer boundaries of a territory to be supplied by an exchange and distributed from this point according to the most advanced practice in multiple, cable distribution, serves the territory in the most economical way, and where a portion of the lines are party lines, the capacity of the cable is from 800 to 1,000 substations.

These figures are based on the average number of telephones per circuit found in a number of our leading cities.

It is noteworthy that the outlying districts are larger users of party lines than the central portion of a city, so groups of subscribers within a radius of four or five miles from the central office can be served much more economically, the expense of operation being lower than of a branch exchange, and the first cost little, if any, greater, if we assume that real estate be purchased, a first class building erected, modern central office equipment installed, and both offices connected by trunks through cable in underground conduit. The underground conduit remains practically the same whether the district five miles from the central office be supplied by the cable direct from the main office, or whether it is served by a branch office with connecting trunks. The additional cost of a four hundred pair cable over the cost of the trunking cable to connect the branch offices, will be considerably less than the cost of real estate, building and branch office equipment. On the other hand, the expense of the extra multiple for the four hundred additional lines entering the central office will be greater, but the extra trunking equipment and multiple, which will be eliminated when branch offices are not used, will, more or less, balance the cost of the main office multiple.

In summing up the advantages and disadvantages of individual and multiple exchanges, we find that large individual offices possess advantages of being cheaper to operate and afford a more prompt and accurate service and are cheaper in first cost.

With multiple exchanges, we find that they are necessary in the largest cities because satisfactory equipment cannot be secured for serving a sufficient number of subscribers. Another strong point in favor of the multiple office is that in case of fire, the service of the entire system is not crippled.

While these systems are handling the telephone traffic of our cities in a fairly satisfactory manner, the day is probably not far distant when they will be superseded by a combination of both, together with the aid of automatic trunking, which will materially reduce the first cost of the telephone system, and also that of operation. The writer has given some thought to a system which, broadly speaking, would be one central exchange from which trunks would radiate to all parts of the city, and terminate in small automatic branch exchanges to which the present form of common battery substation equipment would be connected.

A subscriber upon lifting the receiver would operate in the branch office a line relay, which, instead of lighting a lamp, would energize a simple selector switch that would select a trunk line to the main office which was not busy. The trunk on being connected would operate a line relay at the central office, which would actuate a single selector, and connect an operator that was not busy and in turn select the connecting cord that was not busy, and light the lamp associated therewith, placing the operator in talking connection with the subscriber. Upon receiving the number of the party wanted, which we will say is "Century No. 78," the operaor would insert the plug of the connecting cord in the jack of the outgoing trunk to the Century branch. In operating an ingeniously designed selective key, she automatically and almost instantaneously selects the station called for and starts automatic ringing, which continues until the subscriber answers. Upon inserting the plug in the trunk jack, she extinguishes the lamp lighted by the party calling, and automatically disconnects her listening set from the subscriber's line, leaving the conversation of the two subscribers absolutely private and at the same time leaving her position open for another call. The subscribers upon completing their conversation and restoring the receivers are automatically disconnected owing to the opening of the circuit of the subscribers' line relay, which releases the automatic selector, thus leaving the trunk free for other calls and giving the subscribers an opportunity to immediately call again. It is true there is a plug left in the outgoing trunk, but upon the automatic disconnecting of the two subscribers this cord and plug are cut dead, the busy test taken off of the trunk jacks and a disconnect lamp signal lighted, which notifies the operator to take down the cord, the removal of which leaves the cord so it will not test busy to incoming calls.

With the system as outlined it would not be a difficult problem to handle the extreme development of our largest cities from one central office. With a development of 100,000 telephones which some of our cities have at the present time it would be unnecessary to place in front of an operator more than a few hundred trunk jacks. These being common to this position only, there would be only a few trunk jacks for each branch office for each operator's position. The operator in plugging into one of these jacks would operate a selector which would automatically select a non-busy trunk to the branch exchange; over this trunk the impulses travel from the operator's selective key, which select the subscribers in the branch exchange. This method saves the operator the time and trouble in testing for non-busy trunks and eliminates a great number of trunk jacks which would otherwise be multipled in front of all the other operators.

In medium-sized cities, all outgoing trunks could be multipled in front of each operator. This would eliminate the outgoing trunk selector and the operator would test as usual for non-busy trunks. For incoming calls there would be no equipment placed in an operator's position except a few connecting cords with their indicating lamps. Incoming calls come in over trunks which terminate in a distributing room and from there are automatically distributed to the operator's positions. In large offices, it would be necessary for the incoming trunks to be divided into sections so that the selector would not have to be built so as to distribute to too many operators' positions. Different classes of service, such as measured service, flat rate service, etc., would come in over separate sets of trunks which distribute to sections in which there are operators who handle these only.

The first cost of the wire plant in this system will be very materially reduced owing to the grouping of subscribers in small groups and automatically trunking the same direct to the main office.

It has been found from data compiled from a number of operating exchanges, that one trunk will, on the average, where the exchange is of sufficient size, carry the traffic of 12 to 15 subscribers' telephones, and in this way we gain the advantages of party lines without their attendant evils.

This principle has been taken advantage of to some extent in multiple exchanges, but the full benefits cannot be derived owing to the rapid increase of the number of the trunks with the increase in number of the branch offices.

Digitized by Google

When branch offices are used and connected as just described, 100 branch offices would require 4,950 separate sets of trunks, while with the direct trunking to one central exchange there will be only 100 sets of trunks required or the same number of sets of trunks as there are offices. Therefore, in direct trunking, we would use one set of trunks composed of a large number of circuits instead of 100 sets of trunks with few circuits in each set of trunks.

It has been observed in practice that in offices which have only a few trunk circuits joining another office, the average maximum number of messages per trunk circuit per day does not exceed 70 to 80, while in large offices requiring a great number of trunk circuits, each circuit often averages 157 messages per day. From the data given that trunks from a large office carry more than twice as much business per circuit per day as do trunks from small ones. This is due to the greater fluctuation in traffic in small offices. We thus see that there is a decided saving where the business demands a large number of trunk circuits and in direct trunking where a large number of trunk circuits are used. There is also a saving in the time of connecting and disconnecting due to automatic trunking and in the elimination of order wires, etc.

From this we see there is a decided saving in the trunk circuits where direct trunking is employed. There is also a saving in the time of connecting and disconnecting and in the elimination of order wires. On the other hand, all calls have to be trunked, but in small offices the number of calls trunked sometimes reaches 95 per cent. of the total calls, so the extra trunking is not of great consequence.

This system allows the use of the present common battery telephone set which is simplicity itself and adds no complications to the substations which are scattered over miles of area, all equipment which is liable to derangement being located in the central or branch offices. The branch offices would not require installation of expensive power equipment, for all power required for operating the branch exchanges could be supplied from the central office. Current for talking would be fed from the cord circuits in the central office, where 40 or 50 volts would be used, which would prevent an excessive drop on the long line. This, in connection with the latest transmitters, which are especially designed to work on lines of high resistance, solves the problem of supplying the subscribers who are remote from the exchanges.

In case the branch exchanges are at too great a distance from the central office, the subscribers' loops can be supplied with battery for operating their transmitters from the branch exchanges, only a slight modification in the equipment being necessary. There would be no ringing current required at the branch office and the current for operating the line relays and selector switches would be small and could be supplied by local storage batteries charged from a 110-volt circuit over trunk wires from the central office or from the local lighting circuit. This plan was devised by the writer a few years ago for supplying the private branch exchanges for the Cuyahoga Telephone Co., of Cleveland, O. This company is now operating nearly one hundred private branch lamp signal boards from storage batteries charged over trunks as described. The results are proving satisfactory and economical. In charging the batteries sufficient resistance is inserted in the feed wires so that the batteries receive the proper amount of current to maintain them at full charge.

Every two weeks an inspector tests the specific gravity of each cell, takes a voltage reading and examines the private branch board. The cost of maintenance is in this way reduced to a minimum.

The space required for locating these branch exchanges would be small. An inexpensive room in one of the large office buildings would answer very well for supplying such buildings in the business districts. In the outlying districts suitable quarters could be secured at a much lower cost than where expensive equipment has to be housed and operators' quarters provided. The greater the number of branch exchanges, the less the wire mileage for each subscriber. One main underground cable could be tributary to a number of small branch exchanges. The system, besides being more economical in first cost, admits of a decided saving in operating expenses. The number of operators are materially reduced. The trunking or B operators are eliminated entirely and quite a number of the regular A operators, because each operator would be working at her highest efficiency at all hours of the day. She would be constantly busy; the service prompt and uniform; she would never be overloaded, for she can only receive one call at a time, as the automatic distribution sends calls to the non-busy operators. The subscriber in lifting the telephone is immediately put in talking connection with the operator and gives the number desired without the request for "number." The operator repeats the same and glances at the keyboard, seeing a lighted lamp, which indicates the cord to be used. Whereupon she plugs into the outgoing trunk jack, presses the selector key which picks out the line desired. Owing to the few number of movements required and because the operator is constantly kept busy, she will probably answer two to three times the number of calls usually handled in the same length of time. Night service, Sunday service and such portions of the day when the load is light, a number of the operators could be dispensed with owing to the fact that the first operator's positions receive all the calls and the last positions are called into service only during the rush hours of the morning. The system as outlined reduces the first cost of the wire plant, eliminates all the multiple answering jacks and line lamps, and reduces the operating expenses and uses equipment composed of parts of the manual and the simpler parts of the automatic and posseses the advantage of unit, multiple and automatic exchanges.*

*Paper read before the International Electrical Congress at St. Louis.

THE TELEPHONE.

Here's to you!
Cheers to you!
Telephone!
Rancor
And spite
And a mighty
Sight
Of
Tender sighs
And
Business lies
Have come
And gone
Along your
Copper highway.
It's nobody's
Biz,
But
Gee Whiz! Think
Of the
Kisses of
1000's of
Misses
You've had.
Execrable
Taste to
Waste
A kiss on
You —thing of
Rubber and
Steel
And
Revolving
Wheel and
Diaphragm.
You're only a
Sham.
You haven't a
Tongue
Or a
Lung,
And yet you
SPEAK!
You haven't
An ear, and
Yet you
HEAR!
Some day you
May
Get
Gay,
And say,
What you'll
Tell will—
Well—
Raise
HELL—O
Central,
Ring Off!

—*Life.*

INDEPENDENTS WIN IN SUPERIOR, WIS.

THE People's Telephone company of Superior, Wis., has won out over the Bell people as far as the fight before the council committee here is concerned. The result is that for the present there will be no further effort on the part of the Bell people to get their telephones used free of charge to the city hall and other city buildings.

Digitized by Google

TELEPHONY IN CENTRAL TEXAS

By R. M. Jones.

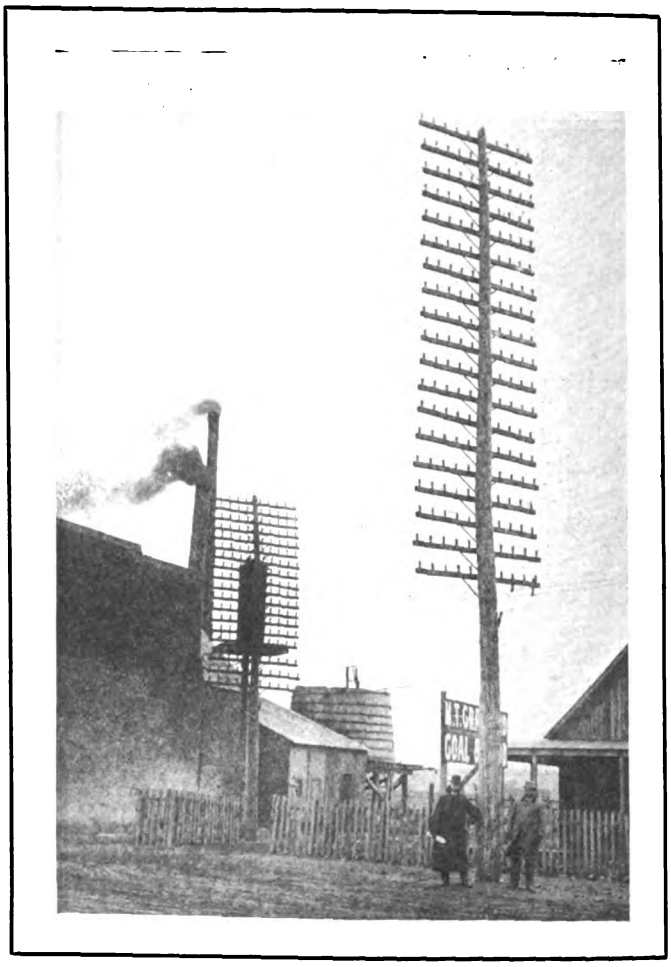
R. M. Webb, General Manager.

THE development of telephones in the Southwestern States has necessarily been slow. The reason for this is the sparsely settled condition of the country, and also to the fact that the Bell had never till quite recently made any efforts to establish systems unless there was a practical guarantee that the returns should be as high in proportion as those secured in thickly populated districts. The advent of competition in the shape of Independent systems changed this state of affairs and now throughout the country districts Independent systems are almost exclusively found and in many parts they have supplanted the Bell.

Texas is truly a State of magnificent distances. The largest in the Union in size, it is also one of the most progressive. From the standpoint of population, however, it is far surpassed by many of the smaller States, but even this condition is rapidly changing, owing to the increased facilities in the way of communication and travel, and through the great opportunities it offers to the man with a progressive spirit.

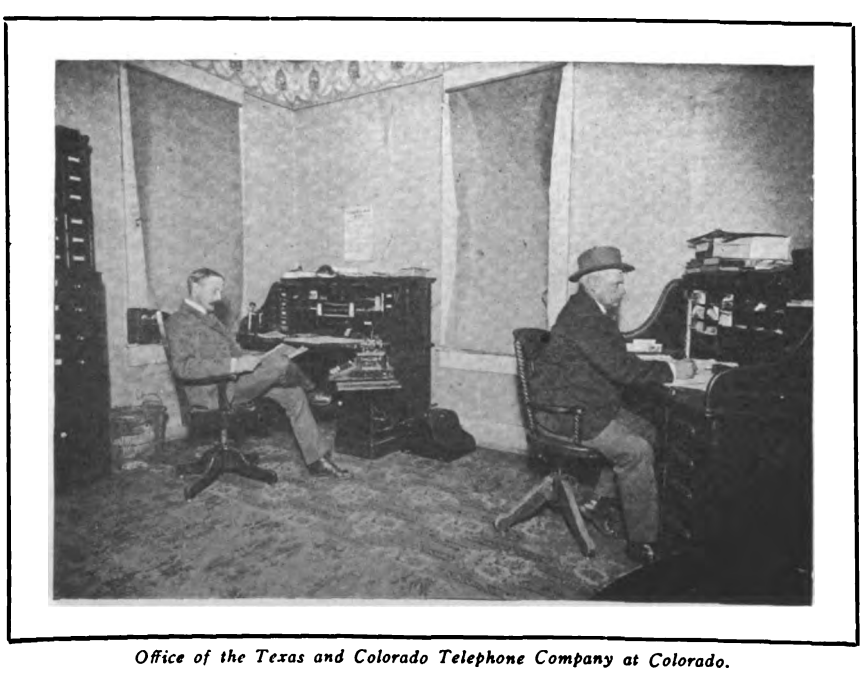
Dating from the commencement of Independent telephony a new condition has arisen which bids fair to outrival all competitors as a commercial agent. Formerly the prime factor in the success of a town was its conveniences for travel. If they were ample then growth was only a matter of a very short time, but now the question that often arises is what are the means for communication? How are the postal facilities? Is there sufficient telegraphic service, and most important of all, is there a telephone system? The telephone is a necessity, and is of more value even in smaller communities than larger ones. That this is true is evident from the enormous number of country lines which have sprung up within the past few years, and which to-day are being constructed in every part of the country.

An illustration of this class of telephone service is well given in a description of the system of the Texas and Pacific Telephone company, which operates in the counties of Mitchell, Nolan,



Termination of Pole Line at Colorado.

Scurry and Taylor, with head office at Colorado in Mitchell county, and branch exchanges at Roscoe, Markel, Snyder, Light and Sweetwater.



Office of the Texas and Colorado Telephone Company at Colorado.

About six years ago a small Independent exchange was opened in Colorado, but owing to adverse conditions little progress was made for the first three years. In 1901 the plant, which then consisted of 85 telephones and one toll line about 28 miles long, was bought out by and reorganized under the name of the Texas and Pacific Telephone Company. At once the business commenced to expand and shortly afterwards several other exchanges were secured, and a system of toll lines constructed. To-day there are 600 miles of toll lines and upwards of 800 subscribers. In the city of Colorado alone there are 280 in a population of 2,000.

This progressive company at present has a capitalization of $40,000, and is on a first class paying basis. The demand for telephone service is so great that a large number of applicants are always on the waiting list. The present officers of the company are J. N. Weakley, president; B. S. Van Luyl, vice-president; R. M. Webb, general manager, and E. Keathly, auditor. Many of the lines run for

Digitized by Google

miles to give service to ranches, and in consequence a number are party lines, although in no instance are the lines overloaded. The largest number placed on one line is six, although a large number are two, three and four party.

The rates charged are $2.50 for business houses per month, and $1.50 for residences. All the instruments are of the bridging type, manufactured by the Sumter Telephone Manufacturing Company of Sumter, S. C. This firm has also supplied the switchboards which are magneto of 100 line capacity. Warner pole changers are used for ringing.

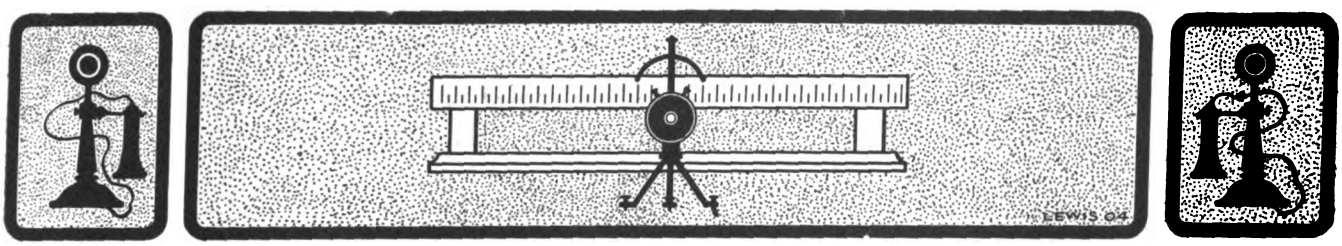
The line construction is first class, poles being used exclusively, although in this part of the country numbers of lines are constructed on wire fences. The circuits are mostly grounded, except the toll lines, but as there are no trolley roads in the vicinity there is very little trouble from noisy lines.

Since there is no competition, development has been very fast, considering the nature of the territory covered. The people are entirely satisfied with the service and consider it as much of a necessity as the mail or railroad.

In closing, a few words about the opportunities that constantly arise in the telephone field will not be out of place, since this article offers a very good illustration.

The general manager of the company, Mr. R. M. Webb, was formerly engaged in business in New York City. On account of failure in health he was compelled to move to some drier climate and chose Texas. After two years spent on a ranch to recuperate, he entered the telephone field, and was instrumental in organizing this company. The results of his management are self-evident. What is true of this case is also true of hundreds of others.

Business ability combined with a progressive spirit make success in every enterprise, and in no other are there better opportunities than in the Independent telephone field. Notwithstanding the great development of telephony in the past few years, it is yet in its infancy. North, South, East and West there are large areas of country where a telephone system would be a boon to the community. The Southwest is one which offers particular inducements in the matter of climate and people.



AUDITING FOR TELEPHONE COMPANIES

By I. D. Gindhart, Jr.

The Auditing Department of a telephone company is gradually becoming a very important one, and as business expands and the control of vested capital finds itself in hands more or less scrupulous and skilful a closer, more vigilant watchfulness upon the income and disbursements of corporations is required. This is the need of the day and has been met throughout the country by the formation of audit companies and auditors in charge of their departments.

"*Auditing is a necessity.* How much so depends on the management and size of the company. Railroads have long ago conceded that auditing and accounting went hand in hand with the operating departments and their auditors and statisticians to-day held enviable positions, consulted by the presidents, general manager and board of directors.

"The opinion is sometimes expressed that the cost of placing statistical information in the hands of the parties to whom such information is of value, is greater than is warranted by any benefit accruing. But the fact still remains that all large companies to-day find it profitable to send thousands of dollars annually in the preparation of reports to show all details of the business and to place before the executive heads the cost of each department, that all leaks may be stopped.

"Auditors agree that auditing is an art; that is, auditing in its broader sense, which includes all branches of accounting. Bevee tells us, the art of a thing is first its aim, and next its manner of accomplishment. The aim of the audiitng department is primarily a careful record of all income (crediting the respective sources) and all disbursements are charged in such a manner that the expense of the business may be easily determined.

"Comparative records will often cause the dismissal of a careless and expensive district manager and prove that the industrious, conscientious manager is making things pay. A cost book showing itemized cost of construction will oftentimes show an unnecessary increase of cost of one line over another. A cost book is easily kept by having a cost number for each new undertaking and posting all material labor and proportion to general expense to the cost and closing the account when work is completed.

A daily report of stock receipts and disbursements is an excellent check upon storekeepers, and it is well that semi-annual inventories be made to adjust stock ledgers.

"Comparative reports of earnings per trunk line show when a line has exceeded the estimated carrying capacity or indicated if it is operating at a loss.

Taking care of toll business was the bugaboo for a time and many were the methods of the settlements, but now it is an easy matter, as it is shifted upon the traffic association.

Every telephone corporation has its own method of auditing. These different methods are extremely annoying to the purchaser of bonds or stocks and oftentimes tends to confuse one's ideas of actual value of the properties.

We must look forward to the day when consolidation will take place and companies will be grouped together and *standardization* will be the keynote.

To this end I suggest a telephone auditors' association for the purpose of standardizing the accounts, using a system elastic in its principles applying to the small as well as the large.

Such an association for street railway accounting met in Boston in 1898 and the system adopted then is now in use in over 100 large street railway companies. A standard and uniform system of accounting is of much importance as the standardization of equipment and lines and the benefits accruing from it will be found to be as great.

Paper read at Convention of Penna. State Tel. Assn. at Harrisburg.

OVERTURES DENIED.

THE Central Union Telephone Company has sent representatives into Montgomery County, Ind., to make overtures to the farmers' telephone companies. The purpose is to connect up these lines with the Central Union toll system. The overtures have not been accepted, as the farmers' companies remember that a few years ago the Central Union Telephone Company did all in its power to prevent their organization and the conducting of business. The farmers' lines prefer the Independent toll system and will not co-operate with the Central Union.

OPPORTUNITIES IN NEW ENGLAND.

NEW ENGLAND was for a while considered without the pale of Independent telephony. During the last two or three years, however, the people have begun to realize the situation which had become untenable years previously in other districts. It might be supposed that being the home of the Bell that in the matter of service nothing could be desired. Such is not the case, for there are a large number of New England towns in which the Bell service is worse than in any other part of the country. Grounded lines are common, old Blake transmitters abound, and the rates are kept up to the highest possible figure. These being the facts, it is not surprising that the people, realizing the benefits that had accrued to other communities through the advent of Independent telephony, should have espoused the cause wherever possible, and to-day there are upwards of two hundred Independent companies in operation. That there are not a much greater number is due to the well-known news bureau tactics which have been the Bell's most valuable stock in trade.

The opportunities for further development are unequaled. The large number of manufacturing cities so closely situated; the demand for telephone service at reasonable rates, and the necessity for up-to-date apparatus makes this field an extremely promising one. In conjunction with local systems toll lines are needed to join together the various interests so that a more formidable front may be made to the enemy.

Portland, Me., is an illustration of the possibilities open to progressive Independent companies. The system of the North Eastern Telephone Company has been in operation only a short time, but has some 3,000 subscribers. The company recently sent out a circular letter requesting opinions upon its system, and in almost every instance the replies received were enthusiastic in praising the service, and only a very few had any words of favor for the Bell.

In the State of Maine there are 75 Independent telephone companies. Massachusetts has only 37, yet in every way it is a much better field. Lynn, one of its most important cities, has no Independent system. Here is an opportunity for development. There are numbers of other places that could be mentioned, but this illustration will suffice to draw the attention of the Independent operators to a field which bids fair to equal any so far exploited.

TO FIX EXTENSION RATES.

CORPORATION COUNSEL TOLMAN, of Chicago, will be asked for an opinion as to the right of the city to govern the charges made by the Chicago Telephone Company in making service extensions by means of switchboards and desk transmitters. The opinion is asked by the council committee on gas, oil and electric light in consequence of an order introduced at a recent session of the council. According to Alderman Blake, the ordinance of 1899, under which the company operates, made no provision for the rates to be collected for improved service by means of the private switches. Many complaints have been made that the charges are extortionate.

According to the officials of the Chicago Telephone Company a charge of $36 annually is made for every trunk line, and $12 for every terminal line for all switchboards. No switchboard, however, will be installed unless two trunk lines are paid for. The operator of all switchboards is paid by the subscriber and all changes and removals from one place to another of all telephones are paid for by the subscriber.

MUNICIPAL OWNERSHIP IN GREAT BRITAIN.

THE municipal ownership of certain utilities has been a factor of much importance in Great Britain. The supply of gas, water and electricity has in a number of cities either been operated or controlled by the municipal authorities. Quite recently the subject of telephone service has been brought before the city councils, and it bids fair to bcome another of the public service institutions under control of the administration of towns and cities.

There is, however, one drawback to this wholesale ownership by the corporations of the various British towns, and that is that the telephone is considered as a government monopoly and consequently comes under the control of the General Post-Office. The head of that department in his annual report stated that no new permits had been issued for the establishment of municipal telephone systems during the past year, from which the conclusion may be drawn that in the future the telephone will be directly in charge of the government in a similar manner to the telegraph.

Whether the municipal authorities are able to conduct a telephone system as well as a private corporation is doubtful, and can only be determined through experience gained over a long period of time. Because the first results show a saving in cost and operation, it is not certain that as time goes on the returns will be adequate to take care of depreciation in the plant or to allow for the application of more modern principles to its operation.

At the present time municipal exchanges are in operation in Glasgow, Brighton, Portsmouth, and Swansea, and one is under construction in Hull. Of these Glasgow has the largest list of subscribers, it being in the neighborhood of 11,500, with an average revenue per telephone of $21. From this the post-office royalty of 10 per cent. must be deducted before applying the surplus to funds for depreciation, interest, and the sinking fund.

In Brighton the system includes some 800 odd subscribers, but is in competition with a private corporation. The system in Portsmouth was started in March, 1903, with a flat rate of $28.61 for unlimited service and an average income per telephone of $17.54. Although it is reported there was a surplus of $11,095 after paying all fixed expenses, yet if expansion, such as might be expected, took place it is doubtful if the following years will show as good results.

At Swansea the system has not been in operation a year, so that no data is obtainable. So far 750 subscribers have been secured and additional orders have been received to bring the total up to about 1,000. The exchange which will be opened in Hull in the near future has secured a prospective list of 1,000. The rates will be $30.68 for unlimited service, $28 for second and subsequent connections, and $14.61 for measured service with an additional charge of two cents for each outgoing call. This latter class of service seems to be increasing in favor, and since it offers another solution to the question of measured service the result of its use should be carefully watched.

Of these cities all of them have a population of over 100,000, and in Glasgow it is in the neighborhood of a million. Comparing these figures with the number of telephones it will be seen the proportion of subscribers is much lower than in this country. If the development is as rapid as it has been here no matter how bright the outlook may be now, to the future alone must we look for confirmation of the advisability of municipal control of the telephone industry.

The Telephone in the Courts

Conducted by A. H. McMillan.

Readers are invited to submit questions on any point of Telephone Law. They will be answered and explained on this page.

RECENT DECISIONS ON ABUTTING OWNERS.

Will you please let me know if any decisions have been made on the question of whether a telephone company is liable to damages for setting a pole and anchoring it in front of a man's premises. We have a suit against us at this time by a property owner near whose gate we set a pole and anchored it with guy wires. He asks $150 damages and abatement of the nuisance.

If you have any decisions along this line, I would like to have them.

U. T. Co.

THERE have been a great many decisions upon the question to which you refer; some of them holding one way and some the other. One rule is that if the fee to the highway is in the adjacent owner, the use of the highway only for the purpose of public travel having been granted, then the erection of poles and wires of the telephone company will constitute an additional burden, but if the fee is in the public, then there can be no valid objection to the grant by the public to the telephone company to so construct its line. This is the rule in Illinois, Kentucky, Kansas, Maryland, Mississippi, New York, Ohio and Virginia.

The other rule is that poles and wires of the telephone company are not an additional servitude on the highway and entitle the abutting owner to compensation. This rule is followed in Indiana, Massachusetts, Michigan, Minnesota, Missouri, Montana, Pennsylvania and South Dakota.

The following are some of the most important cases upon the latter rule: Kirby v. Citizens' Telep. Co. (S. Da.), 97 N. W. 3; McGee v. Overshiner, 150 Ind. 127, 49 N. E. 951; Irwin v. Great Southern Telep. Co., 37 La. Am. 63, 1 Am. Elec. Cases 709; Pierce v. Drew, 136 Mass. 75; People v. Eaton, 100 Mich. 200; Cater v. Northwestern Telep. Exch. Co., 5 Am. Elec. Cases; Julia Bldg. Assn. v. Bell Telep. Co., 88 Missouri 258; Hershfield v. Rocky Mt. Bell Telep. Co., 12 Montana 102; York Telep. Co. v. Keesey, 6 Am. Elec. Cases 107; see also Rocky Mt. Bell Telep. Co. v. Salt Lake City R. Co. (District Court, Utah Ter., 3d Judicial District, 1889), 3 Am. Elec. 356.

DAMAGES FROM CONDUCTION.

Recently the Electric Light people installed in their underground ducts some common insulated wire with poor insulation. It was not intended for any such purpose and the negative side leaked into the ground. They made a test and found that in three blocks the leakage was 15 amp. We have a telephone cable in the same alley in a duct about three feet distant and our cable was destroyed. We maintain that they are liable for the destruction of the cable in that they are not using material that will protect others. "They maintain that we cannot hold them responsible. That others are using the same thing in other cities and do not suffer." One thing is certain, if they use that kind of work and have leaks, as they will have, we cannot operate a cable unless we insulate the whole cable from the ground, and that is impossible.

Please discuss the question as fully as you can. L. Tel. Co.

THE laws of Wisconsin provide:

> Section 1. It shall be the duty of each and every electric light and power company and of each and every person engaged in the transmission of electrical energy in this State to provide by suitable insulation, guard wires or other means, against injuries to persons or property, by leakage, escape or inductions, of any and every current of electricity.
>
> Section 2. Neglect of any of the above provisions shall entitle the person or corporation injured thereby a preliminary injunction preventing further use of such current until said section has been complied with. Laws of Wis., 1889, Chap. 375.

You are undoubtedly right in your contention that the Electric Light Company is liable for the destruction of the cable, because this destruction resulted from their negligence in not properly insulating their wires. The injury was caused by what is legally termed conduction, which is a discharge or escape of electricity into the earth from the wires or plant of one electrical company, by which the wires of another electric company are affected. The Supreme Court of Wisconsin discussed the question in the case of Wisconsin Telephone Co. v. Eau Claire Street Railway.

This case was an application for the injunction at the suit of the telephone company to restrain an electric light company from operating its road so as to interfere, by its strong currents of electricity, with the use of the telephone system. The injunction was denied, because it appeared that the single trolley system used by the railroad company was the best system known, while the telephone company could avoid injury to itself by adopting the metallic circuit. The court said that the language of the statute seemed full enough to cover the case of the plaintiff, as well as that of the defendant. "The object of that suit is to prevent leakage of electric wires permeating the earth and causing damage to others, and by its terms to prevent the plaintiff from allowing the leakage to escape into the ground, as it does in the case of the defendant, and hence if I am right in this, it follows that, if the defendant was in the wrong in not providing for a safe return of the electricity, that the plaintiff is just as clearly in like position, differing only in the amount of the electricity that is allowed to escape."

The court further said that if the adoption of the metallic circuit on the part of the telephone company was made necessary by the wrongful act of the railroad company, that the telephone company could sue the defendant at law and recover whatever expense was incurred in making the change. Wis. Supreme Court, 1890, 3 Am. Elec. Cases, 383.

LICENSE TAX ON POLES.

THE Supreme Court of Arkansas has passed upon one of the vital questions in telephone law in the recent case of the city of Fort Smith vs. Hunt. The city of Fort Smith granted the Fort Smith & Van Buren Lighting & Transit Company a franchise amounting to a contract, prescribing the terms and conditions on which the company could erect poles in the city streets. The city subsequently passed an ordinance requiring every person and corporation who should erect and use any poles on any of the city streets to pay "as a license therefor, twenty-five cents for each pole." It also required each company to return a statement of the number of poles which it had in the streets, avenues and alleys of the city; and for neglect to return said statement imposes a fine of not less than five nor more than twenty-five dollars. Hunt, the manager of the company, refused to make the statement and was prosecuted for the violation of the ordinance. He was acquitted in the lower court and the city appealed. The company took the position that the license imposed by the ordinance was illegal.

The court held that the ordinance was not invalid as demanding a rental for the use of the streets, but the sum required to be paid was lawfully exacted as a license for the purpose of defraying the expense of regulating and controlling the use of such poles under the police power of the city. The defendant contended that the regulations contained in an ordinance existing at the time of the granting of the franchise to the company were all regulations that could be made by the municipality for the control of the company. The court held, however, that the police power of the city, in respect to the poles, was not exhausted by the former ordinance; nor was it thereby prevented from afterwards prescribing their rules and regulations for the same object, or from exacting a license fee to defray the expense of enforcing the already existing rules and regulations. Neither was the police power of the city divested by the contract between the city and the electric light company.

IN THE OPERATING FIELD.

THE INDEPENDENTS IN PENNSYLVANIA.

THE Pennsylvania law requires annual statements from all incorporated telephone companies operating within its borders. The secretary of internal affairs has compiled, in his report for 1903, the reports of eighty-seven telephone companies, nine being Bell companies and seventy-eight Independent companies.

The total number of anti-Bell telephones reported in use by seventy-two companies was 62,077, while the total reported investment for these seventy-two companies was $19,839,045, or an average investment of $320 per telephone. The total investment recorded for seventy-six companies was $18,867,822, while the gross income recorded for the same seventy-six companies was $1,352,987, or an average annual gross income of 7 per cent. on each dollar invested. Nearly one-fourth of these competing companies are mutual organizations, not operated for profit in the strictly commercial sense.

BELL SERVICE ILLEGAL IN IDAHO.

DISTRICT Judge Stewart, at Boise, Idaho, recently, in passing on a telephone contract, held that the Rocky Mountain Bell Telephone Company was not legally qualified to transact business in this State, having failed to comply with the new law requiring the filing of articles of incorporationn. The case will be appealed to the Supreme Court. If affirmed the effect will be far reaching, invalidating every contract with the company in this State.

THE TELEPHONE SITUATION IN ALABAMA.

IN the State of Alabama there are upwards of forty-three Independent telephone companies, but these do not cover the entire State; in fact, there are plenty of opportunities for many more. Recently a franchise was granted to Geo. L. Wilson, general manager of the Oconee Telephone Company, of Walhalla, S. C., for a term of twenty years in Pell City, St. Clair county. This is a thriving little town on the lines of the Southern railway, between Amston and Birmingham. A metallic circuit standard construction system will be installed. Work commenced on October 1, and every effort is being put forth to complete the system at an early date. So far fifty subscribers have been secured, with prospects of double that number as soon as the system is in operation. The rates will be $3 per month for business and $2 per month for residence service.

NEW ADVERTISING PLAN.

MANAGER George C. French of the Wisconsin Telephone Company, has just completed an advertising scheme which is making people who fear constables and the minions of the law nervous of nights. It is a reproduction of a superior court subpoena with the difference that the words superior court are changed to superior office, and the name of the judge is taken by that of the manager. The receiver is commanded to appear at the office of the Wisconsin Telephone Company and show cause why a telephone has not been installed in his residence.

Some of the replies which have been received and incidents which have occurred are amusing. One man who had his telephone taken out some time ago because he had failed to pay up though he was being sued, and forthwith hastened to the office and squared the account, asking the manager to keep the matter quiet, for he had never been arrested and didn't want the neighbors to know about it.

The other day Manager French's telephone bell rang and a gentle voice inquired if the manager was in and when she was informed she said, "I think it is very hard of you, Mr. French, to ask me to come way down town when you ought to know that it is impossible for me to leave the house."

"But I don't insist that you should," said the manager, "but don't you think you ought to put a telephone into your residence?"

A letter scrawled in lead pencil was received yesterday which started out as follows:

"We want to let you know that we don't want no telephone in our house, and this settles it."

THE TELEPHONE AT THE AUTOMOBILE RACE.

TO prevent the troubles incident to reporting by telephone, which occurred during the Gordon Bennett race in Germany, the committee in charge of the recent automobile race on Long Island, N. Y., made arrangements for telephonic communication, the details of which were placed in the hands of a competent engineer.

The timers had their own telephone system, connecting the official stand with the timers located at the two controls, one at Hicksville and the other at Hempstead.

In addition to this elaborate system the judges had a system for their own use connecting with various points on the circuit, particularly at the four turns—Jericho, Plain Edge, Queens-Hempstead and Queens-Jericho.

These systems required 500 miles of wire. To guard against breakdowns four inspectors and repair men, mounted on motor bicycles, were located at each of the four turns.

WEATHER BUREAU UTILIZES THE TELEPHONE IN TENNESSEE.

THE United States weather bureau is planning to have all reports from Tazewell, on the Powell river, and Speers Ferry, on the headwaters of the Clinch river, made at the Chattanooga office of the bureau by telephone, as all the reports from the upper headwaters are received. The local office has referred the matter to headquarters at Washington, which is considering the advisability of having the reports made here via Knoxville.

THE TELEPHONE IN A LUMBER REGION.

A RECENT innovation which is greatly appreciated by the lumbermen in the vicinity of the Kennebec river in Maine is a telephone line which runs from the Forks of the Kennebec through the deep woods to Moosehead Dam and up the Dead River. By means of this telephone service, the pitch of water and the movements of logs can be made known and controlled, whereas formerly when it was desired to have the gates of the dam closed or log-sluicing stopped it was necessary to send messengers through the woods—a long and hard journey, with the messenger often arriving too late to do any good.

NEW SYSTEM FOR AMSTERDAM, N. Y.

THE Amsterdam Automatic Telephone company is entirely reconstructing its system. The growing demands for extended service caused the directors to decide to install a modern system which would be able to take care of the needs

Digitized by Google

of the city for a number of years to come. A complete aerial cable plant is being installed by Le Roy W. Stanton, which will have an approximate capacity for 1200 circuits.

The contracts for the switchboard and apparatus will be let on Oct. 20, and call for a common battery switchboard, 1080 lines installed with an ultimate capacity of 3,000. It is estimated the work will be completed and the exchange in operation by Jan. 15, 1905. A novel feature in conjunction with the system is that auxiliary power for the charging machines will be furnished by a turbine of the Pelton wheel type. The water pressure is secured from a pipe line coming from the Adirondack mountains. The service will be of three classes, direct wire, and two and four party lines. This system, when completed, will be one of the best in New York State, and will be able by means of trunk and toll line service to reach almost every Independent system in the State.

CONVENTION CALL OF INTER-STATE INDEPENDENT TELEPHONE ASSOCIATION

LOUISVILLE, KY., September 8, 1904.

DEAR SIR:—

The next annual convention of the Inter-State Independent Telephone Association of America will be held in Chicago, December 13, 14 and 15, 1904, and not at the World's Fair, because the business to be transacted is too important to be interfered with by sightseeing.

Our next convention will be the most important in the history of Independent telephony.

The special committees appointed at the last convention, and empowered to act on questions of vital importance, have worked diligently all this year, and their reports at the next convention will be conclusive evidence that they have accomplished more for the general good, permanence and protection of the Independent movement than any and every thing that has been proposed or accomplished.

Every Independent operator in the United States is personally involved and financially interested in the work of these committees and must be present to hear the reports, and endorse the work they have projected.

Certain manufacturers determined a year ago to try to kill the Inter-State Association, but failed to accomplish their aim at the last convention. Now they are suggesting and proposing all sorts of schemes, viz.: the formation of a new association, etc., etc., all of which can mean but one thing, and that is they can not control the Inter-State Association, and are trying to prevent the special committees from accomplishing the work indicated and outlined at the last convention.

We operators must stand together and attend to our own affairs.

Please sign enclosed application for membership if you have not already done so, and return same with $5 to cover your dues, so you will be prepared to take part in the work of the next convention.

Respectfully,

H. A. BARNHART, President.
E. M. COLEMAN, Secretary.

REORGANIZATION BRIEFLY OUTLINED.

Statement of plan outlined and adopted by the Special Committee, appointed at the last Annual Convention of the Inter-State Independent Telephone Association of America:

1st. To incorporate the Association, without stock, for the purpose of co-operation and protection, and not for profit.

2nd. To open regular permanent Headquarters, to be the office and center of the Association, and to which all members shall have access, both in person and by mail.

3rd. To establish in said Headquarters three distinct Bureaux or Departments, as follows:

1st. INFORMATION AND STATISTICS.
2nd. PROMOTION AND PROTECTION.
3rd. UNIFORMITY AND STANDARIZATION.

The object in establishing the first Department is to thoroughly gather all possible data, as to investments, construction, equipment, rates, etc., from every company in the United States.

Then carefully compile and tabulate all such statistics.

Then prepare maps of every county and State, showing the location of every Independent exchange and toll line in this country.

All such statistics and maps to be furnished only to the members of the Association.

The object of the second Department is to furnish such information and assistance, as is possible, in any attempt of Independents to enter new fields, and to more effectively hold the territory already occupied by the Independents, against any attack of the Bell Co.

The object of the third Department is to encourage in all possible ways the adoption of only the best high grade apparatus, modern substantial construction, uniform rentals and tollage, all of which is absolutely necessary and exceedingly important to the Independent movement generally, and essential to each operating company especially.

To enable the Inter-State Independent Telephone Association to successfully push the work outlined, we have incorporated the Association and devised a plan to finance the Association, as indicated in the enclosed Membership Agreement, which we urge you to sign at once.

H. A. BARNHART,
C. E. HULL,
E. M. COLEMAN,
O. REX.
SPECIAL COMMITTEE

MEMBERSHIP APPLICATION AGREEMENT.

To the Inter-State Independent Telephone Association of America:

Application is hereby made for a five years' membership in your Association in compliance with the provisions of your By-laws, which fix annual dues at $5.00 per year, payable on or before the first day of April of each year, the same to be applied to the general expense necessities of the Association.

This membership is taken with the explicit understanding that members are to have the full co-operation and assistance of the said Association in all complications which may arise in their business, involving the general welfare of Independent Telephone interests. And it is further agreed that in the event the annual dues should prove inadequate at any time to fully protect the general interests of the membership of the Association, then the Executive Board is authorized to levy a minimum assessment to meet the emergencies, the same to be based on a uniform rate not to exceed one cent per telephone in use, and ten cents per pole mile toll line, of all property owned by members of the Association.

And it is further agreed and understood that all members will report at once, to the Secretary of this Association, details of any danger which may threaten the Independent Telephone interests; that members shall have free and prompt advice from the Association on all questions affecting the general welfare of the Independent Telephone business of the country, and shall have access to all statistics compiled by the Association, and full membership, with authority to sit and vote in all regular and called meetings of the membership of the Association.

Enclosed find $5.00 in payment of annual dues for this year, and on receipt of which please forward certificate of membership to

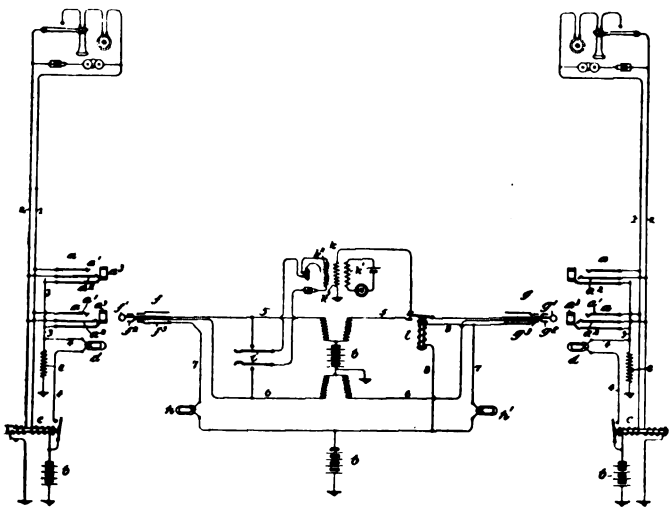
TELEPHONE PATENTS

COMMON BATTERY SWITCHBOARD CIRCUIT.

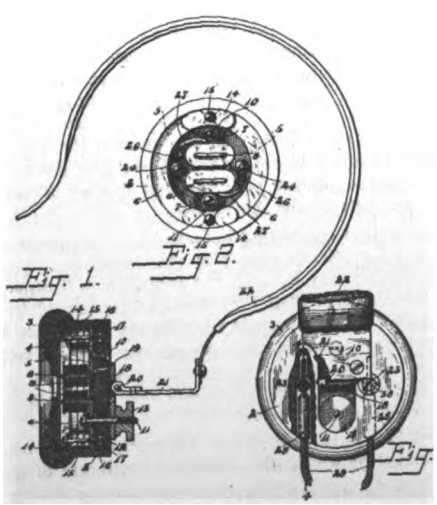
F. R. McBerty, of Evanstown, Ill., patents (No. 796,760) and assigns to the Western Electric Company, of Chicago, Ill., a common battery switchboard circuit. The object of this invention is to so arrange the switchboard circuit that the



operator shall not accidentally flash the signal lamps and thus injure them. The circuit is shown in the accompanying illustration and its operation is as follows: When the subscriber removes the receiver the line relay *c* is excited, closing the local circuit *4* and illuminating the signal lamp, the operator responds by inserting the answering plug *f* uniting conductor *7* with conductor *3*, thereby placing the supervisory lamp *h* into parallel with the line lamp *d*. The resistance of these lamps is adjusted relatively to the battery *b* that when both are in parallel, including the resistance in *e*, neither lamp will be lighted, but if one of the branches is closed there will be sufficient current to light the lamp in that branch, notwithstanding the presence of the resistance, *e*.

TELEPHONE RECEIVER.

R. H. Manson, of Chicago, Ill., patents (No. 769,658) and assigns to Kellogg Switchboard & Supply Company, of Chicago, Ill., an improved receiver. The object of this invention is to pro-



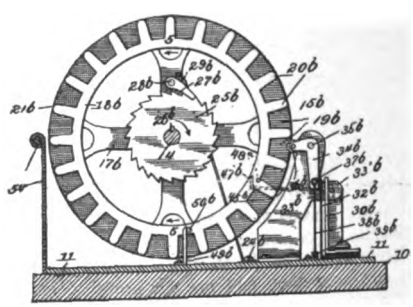
vide an improved receiver of the watchcase style, so constructed that the binding posts carrying the cord terminals are placed entirely within the case of the receiver, as is shown in Fig. 3. By this means all of the metal portions of the cord are protected and short circuits are prevented. In addition, the general design of the receiver is such as to make the one particularly compact usually portable and comforable for the operator to wear.

SUBSTATION SET.

E. E. Yaxley, of Chicago, Ill., patents (No. 769,125). In this patent Mr. Yaxley sets forth the idea that in some instances the vibrations of the bell of a telephone substation are conveyed to the receiver after it has been removed from the switch-hook and produces a disagreeable singing. Mr. Yaxley's invention consists in providing a damper in the form of a lever, which, when the receiver is removed, comes in contact with the gongs of the call bell and stops their vibrations.

ELECTRIC CIRCUIT CLOSER.

Mr. J. K. Norstrom and Henry M. Graif, of Chicago, Ill., patent (No. 769,228) and assigns to Automatic Telephone Company, of Chicago, Ill., an improved selective signal device. This invention relates to improvements in electric circuit closers especially adapted for the so-called automatic telephone systems. The general features of the device are shown in the illustration. The inventor provides a base plate 10 upon which a rotating disk 5 is placed. This wheel disk rotates freely in one direction and is provided with a toothed wheel and pawl connected by means of a spiral spring which returns the wheel 5 to its normal position after it is once propery set. Upon the circumference of the disk numbers are set which correspond to the contact points 20*b*. A



bell crank lever 34*b* is provided, which operates contact springs 32*b* and 38*b*. When the wheel is rotated left-handedly it raises the bell crank lever away from the contact spring, but when it is rotated right-handedly every tooth which passes the bell crank lever causes it to infringe upon the contact springs and thus close the circuit.

SELECTIVE SIGNALING SYSTEM.

W. S. Burnett, Milwaukee, Wis., patents (No. 768,558) an improvement in selective signaling, based upon the familiar step by step method for making circuit connections at the various substations. The invention is a decidelly complicated one, requiring four pages of drawing for its explanation, and needing more room than our space affords for a comprehensive abstract. We recommend those interested to secure a copy of the original patent.

ANTISEPTIC DEVICE FOR TELEPHONE TRANSMITTERS.

T. R. Owens, of Los Angeles, Cal., patents (No. 768,768) and assigns to H. L. Cutter, of Los Angeles, Cal., an improved antiseptic device for telephone transmitters. The object of this invention is to provide an antiseptic protective device for the mouthpiece of a telephone transmitter. The inventor provides a roll of antiseptice paper which is mounted on a spindle set over the mouthpiece of the transmitter in such a manner that the sheet of paper can travel in front of the mouthpiece. As fast as the paper is used, a fresh supply may be drawn from the roll and the old piece destroyed.

QUERIES

Questions on any subject relating to telephony will be answered on this page.

PILOT LAMP INSTRUCTION CIRCUIT.—(435.)

Can you give me a diagram showing the wiring of the pilot lamp instruction circuit as used in central offices? K. O.

The arrangement of the circuit requested is shown in the accompanying Fig. 435, the jack being located at the manager or chief operator's desk, or being multiplied throughout as many desks as may be desired. Upon the insertion of a listening plug in this jack, the upper contacts are closed and the battery circuit closed through relay *A*, which in turn serves to close the circuit through the relays *B*, which are connected in series and thus light the pilot lamps, one of which is located at each position. The operator thereupon goes in on the instruction circuit and is

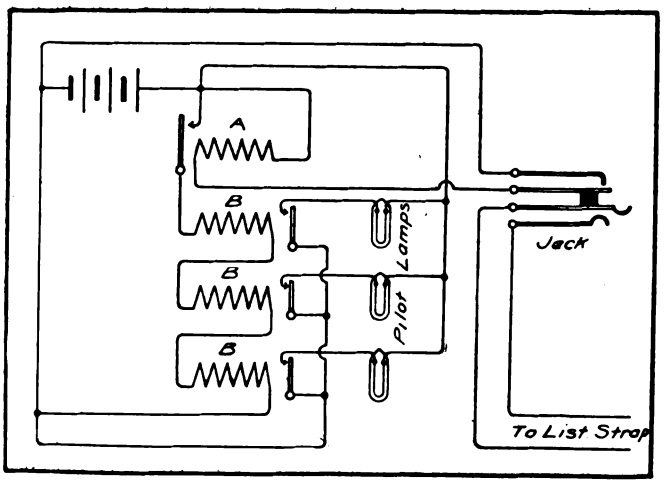

Fig. 435.

given the desired information. As the relays *B* are wired in series it is customary to provide a number of the *A* relays, each of which controls the operation of several *B* relays; for this purpose the *A* relays are connected in parallel and the operation of all of them controlled by the jack.

ROUTE OF POLE LINES.—(436.)

We have secured the right of way for a pole line on the same side of the street as a power line. We also have the opportunity of running the line around another route which is about a mile longer. Our manager says it would be better to do this even if the cost of the line is more, as the other way we would be troubled with noise. Please advise us. J. A. T.

IN our opinion it would be better to take the longer route if there is no possibility of it ever being used by a power transmission line, as you will not be bothered with induction troubles, which are almost certain to occur and will be especially noticeable if the line you propose to construct is used for toll purposes. If you use the route along the line of the power company unless the power line is built high you would need much longer poles to get above it than would nominally be necessary and would cost a good deal more. The telephone lines should not be less than 6 feet away from the power wires. Another important point to be considered is: if your lines have to run above the power lines there is always a liability of danger to linemen climbing up through them and there is the possibility of your lines coming in contact with the power wires and causing serious damage.

RATES.—(437.)

I would like some information as to proper rates to charge for telephone service. We have a magneto exchange of 265 city subscribers, all private lines. Business $2.00, residence $1.00 per month. McClure or common return system is used in the residence districts. I am in favor of raising our residence rates for individual lines to $1.50 per month, making them metallic circuit and also instituting a two-party residence service for $1.00 per month. We have 125 farmers connected with our exchange, thus giving the city subscriber a large territory to get in touch with. I would like to know the prevailing rate in other places, and also whether you consider $1.00 per month for a two-party line high as compared with other towns. G. W. L.

In replying to your query it is exceedingly difficult to answer your question in a suitable manner without more information than that which you convey. From the standpoint of the company it is necessary to arrange rates which will be profitable. The gross income of any company should provide, first, a sufficient amount to cover all operating expenses. Second, a sufficient sum to perpetually maintain the plant in normally working condition, and, third, a sufficient amount to pay current rates of interest upon the capital which is invested in the plant. Upon this basis it will not be difficult for you to ascertain what your gross income should be by calculating operating expenses, estimating depreciation upon your plant at from 10 per cent. to 12 per cent., upon its true cost value and allowing the current legal rates of interest upon your total investments. Having the gross income you can calculate what rates you should charge. If you are operating on the flat rate basis, the flat rate for subscribers would naturally be the gross income divided by the number of subscribers. On the other hand, if you are employing measured service, it would be necessary for you to proportion charges upon the relative traffic of your various subscribers.

NOISY LINE LINE TROUBLE.—(438.)

We have a telephone line 40 miles long that has one grounded line and one metallic line, all No. 12 wire. The grounded line has one telephone 10 miles away, another 30 miles, the third at the end of the route. The metallic line terminates at the switchboards at each end. When the lines get crossed the metallic becomes very noisy. Could we improve matters by tying the three lines together at each end and run them into the board as one grounded line and connect each telephone to the three lines, so as to consider the whole as a grounded circuit? It has been suggested that it is necessary to take down two of the wires and just leave one. Some people say that using the three wires together the current will be split into three parts and die out before it reaches the other end and that it would not be possible to ring over it. We had thought that in strapping the three wires together it would equal a No. 9 wire and therefore would talk better than a No. 12. Can you help us out? R. M. W.

In reply to your query would state that although tying the three wires together would reduce the resistance, yet we do not think that the results obtained would warrant the sacrifice of the two additional wires. From your description we understand the metallic circuit to be a toll line. If this is correct then it is impracticable to place telephones across it. The better plan would be to make the grounded line metallic and tighten up the line wires to reduce the possibility of crosses. At all events, the best solution of your difficulty is to tighten up the line wires and when trouble occurs to send a man out to clear it. The use of iron wire is becoming less every day. Primarily from the fact that high class transmission is only secured by the use of copper wire. From the standpoint of resistance the lengths of your iron circuits do not affect the transmission nor would it be improved by using three wires. There are magnetic properties, which, irrespective of resistance, would cause a poorer quality of transmission than could be secured by the use of copper wire.

CONDENSERS.—(439.)

What is a condenser? R. L.

An article appearing in this issue deals with the manufacture of condensers and the preceding chapter very thoroughly described their operation.

Digitized by Google

THE WEEK'S MESSAGES

FINANCIAL.

EDINBURG, IND.—The Citizens' Telephone Co. has increased its capital stock from $3,000 to $9,000.

HOLT, Mo.—The Holt Telephone Company has filed amended articles of incorporation increasing its capital stock from $10,000 to $30,000.

COLUMBUS, O.—The Citizens' Telephone Company of Columbus is now selling $300,000 of preferred six per cent. stock, the proceeds of which will be used for enlarging the capacity of the plant to 8,000 main line telephones and an ultimate capacity of 19,000 telephones. The stock is said to be finding a ready sale.

DAYTON, OHIO.—The Dayton Savings & Trust Company has closed negotiations with the Home Telephone Company, whereby the former has taken all the bonds of the telephone company, amounting to $250,000.

SPRINGFIELD, O.—The capital stock of the Home Telephone Company of Plattsburg, Clark county, has been increased from $10,000 to $20,000, and the system will be extended.

GRANITEVILLE, S. C.—The Graniteville Telephone Company has increased its capital stock $10,000.

LONE OAK, TEX.—The Citizens' Telephone Co., of Lone Oak, has filed an amendment to its charter, increasing its capital stock from $4,000 to $8,000.

FRANCHISES.

LITTLE ROCK, ARK.—The Hazen Electric Light and Telephone Company has applied to the city council for a franchise. It will put in a local and long distance telephone at once and later, if the city desires, will erect an electric light plant. The company was organized a short time ago and has perfected arrangements to go into operation at once.

COLORADO SPRINGS, COLO.—M. H. Spere and H. C. Kusine have been granted a 20 year franchise to conduct an Independent telephone system in Colorado City.

ARGENTINE, KAS.—The Home Telephone Company of Kansas City has been granted a franchise at this place.

ALTON, MO.—The franchises granted the Fosterburg Farmers Telephone Company in Upper Alton and Alton have been formally accepted.

OMAHA, NEB.—A. B. Hunt, one of the promoters of the Independent Telephone Company seeking a franchise in this city, declares that he is determined to keep up the fight until he gets a franchise.

MIAMISBURG, OHIO.—The city council has granted a franchise to the Home Telephone Company.

GEDDES, S. D.—The Geddes Telephone Company which is constructing a line through this part of the state has applied to the local city council for a franchise to establish a system here.

ELECTIONS.

HUGHESVILLE, PA.—The Muncy Creek Telephone Company has elected the following officers: Dr. T. W. Raper, Lairdsville, president; W. S. Opp, of Opp, secretary, and P. W. Opp, of Opp, treasurer. The work of construction of this line will be started at a very early date.

MILTON, PA.—The subscribers for the new telephone company recently met at Lewisburg, and elected the following board of directors: Hon. H. M. McClure, Hon. G. C. Mohn, Dr. James Kleckner, Captain William R. Folemer, and Messrs. William M. Dreisbach, John P. Ruhl and Charles R. Ruhl. The officers of the meeting were: President, Judge McClure; secretary, John P. Ruhl. Mr. A. Brown was elected treasurer for the ensuing year. The company has applied for a charter under the name of the "Buffalo Valley Telephone Company," the capital stock being $10,000.

COMBINATIONS.

FRANKLIN GROVE, ILL.—The deal whereby the Farmers Telephone Company acquires title to all the material of the Lee County Telephone Company has been consummated. This gives the farmers of the exchange privileges hitherto enjoyed by the Lee Company's system.

WARRENSBURG, MO.—J. S. Haley of Independence has sold the telephone exchanges at Warrensburg and Knobnoster in Jackson County and the connecting tolls in that county to the Kinloch Telephone Company of St. Louis. The Home Telephone Company of Kansas City has connections with the exchanges and toll lines sold.

NEW COMPANY NOTES.

BATESVILLE, ARK.—The Batesville Telephone Company has been organized. The officers of the company are: E. H. Glenn, president; G. B. Ortman, vice-president and general manager, and Miss Cora Maxfield, secretary and treasurer.

COLORADO SPRINGS, COLO.—The El Paso Telephone Company has been organized here with a capital stock of $500,000. The officers are H. B. Hames, president; William Gesford, vice-president; C. D. Taylor, secretary, and Robert McReynolds, treasurer. The company expects to begin work at once and will extend the system throughout the State.

COCOA, FLA.—The Brevard County Telephone Co., capital $5,000, has been chartered to build and operate a telephone line from Cocoa to Eau Gallie, southward fifteen miles; from Cocoa to Titusville, northward twenty miles, and to Courtnay, on Merritt Island, ten miles, and south to Tropic, fifteen miles; to lay cables across Indian river and other navigable streams. H. S. Williams. Joseph Paxton, G. S. Hardee, S. S. Jones and R. N. Andrews are the incorporators.

JACKSONVILLE, FLA.—The Jacksonville Telephone Company has been reorganized by the formation of a new company with J. C. L'Engle, Dr. W. Hume Shine and D. T. Gerow as stockholders and officers of the new company. The new company proposes to take charge of the Jacksonville Telephone Company and to newly equip the plant, making necessary improvements and extensions at once. The capital stock of the company is to be $100,000.

ELKHART, IND.—The Pullman Telephone Company has filed articles of incorporation with the secretary of state with a capital stock of $10,000. The company proposes to establish and operate telephones and telephone exchanges in the following counties: Elkhart, Steuben, La Grange, St. Joseph, Porter, Laporte, Lake, Jasper, White, Starke, Pulaski, Marshall, Fulton, Cass, Kosciusko, Miami, Noble, Whitley, Wabash, Huntington, Allen, Dekalb, Wells and Adams. John K. Johnson, M. E. Cram and M. A. Olds are the incorporators.

GREENFIELD, IND.—The Western Grove Telephone Company has been incorporated here with the following directors: W. F. Thomas, J. C. Hamilton, L. J. Burford and Sylvester Jessup.

LA GRANGE, IND.—The People's Mutual Telephone Association, of La Grange county, La Grange; $10,000; has been incorporated by John W. Evans, P. D. Porter, M. C. Miller.

SOUTH BEND, IND.—The Union Electric Manufacturing Company has been incorporated here with a capital stock of $5,000 by James Holstrom, James MacGregor and Charles T. Wade.

WALCOTTVILLE, IND.—The Peoples Mutual Telephone Company has filed articles of incorporation with a capital stock of $10,000. The company will establish and operate a telephone system in La Grange and Noble Counties with the principal office in Wolcottville. Daniel Strayer, Charles Kandall and A. W. Miller are the incorporators.

TOPEKA, KAN.—These new telephone companies have been incorporated: Farmers' Telephone Company, North Branch, capital $5,000; Grove County Telephone Company, Grainville, capital $5,000.

BATTLE CREEK, MICH.—The farmers of the townships of Newton and Leroy have organized a co-operative company for maintaining a system of telephones from farm house to farm house, with the office and switchboard at Newton Center. All of the farmers of those townships have entered into the scheme.

MONTAUK, N. Y.—The New York and Montauk Telephone Company has been incorporated with a capital stock of $5,000. The directors are: E. E. Snedeker of Jamaica and George E. Hippie, L. G. Johnson, M. P. Brainer, Jr., B. I. Schuman, F. W. Miller and James Gregory of Brooklyn.

KERNERSVILLE, N. C.—The Kernersville Telephone Co., capital $5,000, has been chartered here by W. C. Linville, G. V. and M. V. Fulp and A. N. Linville, of Kernersville, and F. W. Lubert, of Waterbury, Conn. The company has authority to establish an exchange at Kernersville and extend its lines into any part of the county.

NORWALK, OHIO.—The Oil Belt Telephone Company has been incorporated here with a capital stock of $25,000, of which $15,000 is 6 per cent. preferred. The incorporators are: Harry E. Graham, C. M. Graham, E. N. Graham, Edelbert Graham and Joseph R. McKnight.

MENO, OKLA.—The Star Telephone Company of Ringwood has been incorporated with a capital stock of $1,000. The incorporators are W. L. Miller and J. S. Juffman, both of Meno.

GRANITEVILLE, S. C.—The Graniteville Telephone Company has been incorporated with a capital stock of $3,500 by W. A. Giles, T. H. Rennie and G. L. Knight. The line will run from Graniteville to Vancluse, Bath and Clearwater.

ORANGEBURG, S. C.—The Orangeburg and Raymond Telephone Company has been incorporated with a capital stock of $10,000 by E. L. Culler, J. G. Smith and W. W. Culler, Jr.

MEMPHIS, TENN.—The Tri-State Telephone Co., capital $10,000, has been incorporated by Chas. D. M. Greer, Jas. T. Warren, Frank N. Fisher, Lewis T, Kavanaugh and A. Outzen. The company is authorized to do a telephone business and to manufacture electrical appliances.

HUBBARD, TEXAS.—The Hubbard City Telephone Co., capital stock $5,000, has been incorporated by C. W. Hobson, A. L. Collins and Hyde MacFarlan.

JACKSONVILLE, TEX.—The Jacksinville Telephone Co., capital stock $15,000, has been chartered to acquire, establish and maintain lines of telephone in and about the town of Jacksonville. Incorporators: W. H. Sory, W. P. Sory, Jr., and M. L. Sory, all of Jacksonville.

LONGVIEW, TEX.—The Lacy Telephone Co., capital stock $25,000, has been chartered here. Purpose, construction and operation of telephone exchanges and long distance lines in the counties of Gregg, Harrison, Shelby, San Augustine, Nacogdoches, Jasper, Panola, Newton, Orange, Jefferson, Wood, Rusk, Upshur, Franklin, Hopkins, Delta and Lamar. Incorporators: J. C. Lacy, Edwin Lacy, J. W. Yates and Jasper Collins.

PINE BLUFF, WIS.—The Pine Bluff Telephone Company has been incorporated with a capital stock of $10,000.

MISCELLANEOUS.

CHICAGO, ILL.—Arrangements have been completed by the Northern Pacific Road for putting into operation a telegraphone service between Pasco, Washington and Junction, North Dakota, using the regular wires of the company. From Pasco to the Pacific coast and from St. Paul to Jamestown the company already has its own telephone wires, so that the 1300 miles of telegraphone wires will fill the gap between the two ends of the company's service between St. Paul and the Pacific coast.

JACKSON, MICH.—J. B. Ware has made a proposition to the regents of the university to install Citizens' telephones at half the price paid the Bell.

Digitized by Google

LOWELL, MICH.—The Ctizens Telephone Company will increase both business and residence rates $3 per year. There are now 360 telephones in operation.

RENSSELAER, N. Y.—A representative of the Home Telephone Company of Albany is canvassing Rensselaer for subscribers. The company will operate under a franchise granted some time ago by the city council.

TROY, N. Y.—The report that the Hudson River Telephone Company (Bell) had purchased the Glen Telephone Company of Gloversville and Johnstown is denied by General Manager Hawley. An official of the Glen Telephone company admitted that he had been approached in regard to selling, but he would not say by whom.

UTICA, N. Y.—The Home Telephone Company now has 3,016 telephones installed. The company is paying fixed charges and earning nearly seven per cent. on its stock.

CINCINNATI, O.—After a spirited debate between the members of the Millcreek Valley Business Men's Club and representatives of the Cincinnati & Suburban Telephone Company, regarding the recent increase in toll to the northern end of the valley, the club voted to have all instruments removed from Carthage, Elmwood Place and St. Bernard. The club will petition the councils of the various villages to grant telephone franchises to Independent companies.

JENNINGS, OKLA.—G. S. Van Eman and others will organize a company to establish a telephone system here.

CHAMBERSBURG, PA.—The United Telephone & Telegraph Company has made a proposition to a number of Waynesboro business men looking to the lease of the exchange there to a local company.

CHESTER, PA.—Wire thieves stripped the Keystone Telephone Company's line along Academy avenue, in Upper Darby township recently, securing several hundred dollars' worth of copper wire.

PERSONAL.

G. W. Colton has been appointed manager for the United Telephone and Telegraph Company at Lewisburgh, Pa.

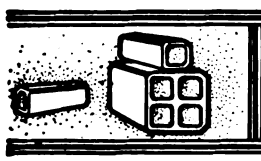
Eugene J. Ellis, county manager of the Sunset Telephone Company, has been promoted to be district manager of a newly formed district, comprising Alameda, Contra Costa, San Mateo, Santa Cruz, Santa Clara, San Benito, San Louis Obispo and Monterey counties and a part of Santa Barbara, with headquarters in Oakland, Cal.

R. C. King has been appointed manager of the Nebraska telephone company's exchange at Wymore, Neb.

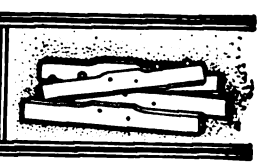
UNDERGROUND.

DUBUQUE, IA.—The Iowa Telephone Company will put its wires underground and will expend $600,000 on the improvement of its system.

NEW CASTLE, PA.—The underground conduit system built by the city is ready for use. The council passed an ordinance compelling all telegraph, telephone and electric companies to place their wires in the conduit.



New Construction in the Field



DECATUR, ALA.—The Morgan County Telephone Co. has completed a line to Trinity and will extend it to Memphis.

AEFLIN, ALA.—A telephone system will be installed here in the near future.

ATHENS, GA.—The Georgia Telephone Supply Co., of Atlanta, will probably establish a local and long distance telephone system in this city.

AFOLKEY, ILL.—The Cedarville-Stephenson County Telephone Company has erected its poles as far as Afolkey.

ZION CITY, ILL.—The council has granted permission to John Alexander Dowie to erect telephone poles and to construct and maintain a telephone line in this city.

INDIANAPOLIS, IND.—The Indianapolis Telephone Company and the new Long Distance Telephone Company will spend $50,000 this season for wire in building toll lines and a quarter of a million in building toll and local lines in the spring.

MUSKOGEE, I. T.—The Pioneer Telephone Co. will construct a telephone system here. Work will commence at once.

MANSON, IA.—P. C. Holdoegel of Rockwell City is remodelling his telephone system at this place and vicinity. It is expected he will spend $4,000 on the system in this section alone and it is needless to say that it will be one of the finest lines in the country. A great many new telephones are being put in over the rural lines and almost every home can be reached in the country by telephone.

WORDEN, KAN.—The Worden Mutual Telephone Company expect to build into Baldwin in a very short time.

MILLBURY, MASS.—A farmers' telephone system will be installed here.

MOUNT SAVAGE, MD.—The Maryland Telephone Company has opened a new toll line to this city.

ACTON, MINN.—The Acton Telephone Company under the direction of H. C. Henderson is making considerable improvement on its lines.

GRAND PLAIN, MINN.—The telephone line to Germantown will be completed this fall.

GREEN PRAIRIE, MINN.—A rural telephone line is to be constructed from New Falls to this place.

HENDRICKS, MINN.—The Lincoln County Telephone Company will install a system here. The company will also soon commence the installation of a system at Idaho.

MADISON, MINN.—The Farmers Mutual Telephone Company recently organized by farmers of Lac qui Parle County has made arrangements for connection with the local exchange. Work will be started at once on the system, which will probably be in operation in a short time.

SILVER LAKE, MINN.—Work has commenced on the new telephone exchange.

WELDON, N. C.—The Home Telephone Company will make improvements to its system here. F. C. Toepleman is general manager.

CANDO, N. D.—The long distance telephone line will be extended north from Cando to Bisbee, Rolla and Perth this fall.

HATTON, N. D.—A new exchange is being installed here.

LEONARD, N. D.—The Leonard Rural Telephone Company is erecting lines out of the city.

WESTHOPE, N. D.—A new switchboard is to be installed here.

COOPERSTOWN, N. D.—The Red River Valley Telephone Company is pushing the work of extending its lines in Clay and Cass counties.

SYDNEY, N. S.—The Nova Scotia Telephone Company will erect a brick building in New Glasgow.

CHATHAM, N. Y.—The Columbia Telephone Company of Hudson will connect with the Chatham Co-operative Company, giving service to Hudson, Mellenville, Philmont, Ghent, Pulvers, Martindale, Crary ville, Hillsdale, Hollowville, Red Mills, Claverack, Humphreysville, Churchtown, Lake Charlotte, W. Taghkanic, Glenco Mills, Livingston, Blue Store, Manorton, Elizaville, Greendale, Nevis, Upper Red Hook, Clermont and Linlithgo.

MIDDLESEX, N. Y.—The Overland Telephone Company is making many new additions to its line plant.

MOUNT MORRIS, N. Y.—Work on the new telephone line connecting the villages of Castile, Silver Springs and Gainesville is nearing completion. The exchange will commence business with about 125 subscribers in the three villages and represents a total of $15,000. Chiefly interested in the new exchange are H. A. Pierce, M. N. Cole and A. B. Windsor.

RENSSELAER, N. Y.—The Home Telephone Company will shortly begin work of erecting its lines in Rensselaer.

SYRACUSE, N. Y.—The Auburn-Syracuse Electric Railroad Company will install a telephone system in conjunction with its road.

BETHESDA, O.—The Belmont Telephone Company will establish an exchange here.

BROWNSVILLE, O.—The Brownsville Independent exchange has seventy-five subscribers in operation and will connect up fifty more within the next month. A toll line is being built which will connect the exchange with the Newark system.

COLUMBUS, O.—The Franklin County Telephone Company is arranging to make a number of improvements in its service outside of Columbus and will attempt to place a telephone at every farm house. At the annual meeting of the company a bond issue of $1,000 was authorized, the money to be used on the proposed improvements.

HAMILTON, O.—The Oxford Telephone Company has commenced work on a number of new lines which will give service to rural districts.

HARPERSFIELD, O.—The Harpersfield Telephone Company has completed its system. It will offer free service from this town to Cork, Trumbull, Rock Creek, Austinburg, Hartsgrove and Thompson unless connections are made from the Madison Telephone Company.

NEWARK, O.—The New Brownsville Telephone Exchange, when completed, will be connected with the Newark Independent Exchange.

CLEVELAND, OHIO.—Secretary F. B. Hoge of the United States Telephone Company stated that before the first of the year Pittsburg will be able to talk to Kansas City for the Independent lines. He said the work of stringing wires over the mountains east of Pittsburg to Philadelphia and Harrisburg is rapidly being completed.

COLUMBUS, OHIO.—The Jackson County Home Telephone Company will extend its lines from Jackson, Pike, Ross, Gallia, Vinton, Lawrence and Scioto counties. Work in the new lines will be begun in the near future.

GENEVA, O.—The Harpersville Telephone Company has reached Geneva, and will give toll service to Ashtabula, Lake, and Geauga counties.

MADISON, OHIO.—The Madison Telephone Company will extend its Geneva line along the South Ridge.

NORWALK, OHIO.—The Oil Belt Telephone Company of this city, which was incorporated with a capital stock of $25,000 will build exchanges at Cygnet, Portage and Jerry City in Wood County with connections and free service with the Independent exchange at Bowling Green. It is estimated that over 150 miles of wire will be strung and 500 telephones installed.

CONNELLSVILLE, PA.—The Tri-State Telephone Company is extending its system. Connection was recently made with the Pittsburg & Johnstown Long Distance Company, giving service with Greensburg. The local company has completed its Flatwoods line and a number of telephones have been connected up. Work is also progressing on the line from Uniontown to Cheat Haven, connecting with the Point Marion Company, giving a direct circuit to Morgantown. The new line to Waltersburg, Smock and Keister will be put in operation shortly.

HOMESTEAD, PA.—The Pittsburg & Allegheny Telephone Company has installed a new switchboard here.

JOANNA, PA.—The new switchboard for the Conestoga Telephone Company will be installed in a short while.

READING, PA.—The Conestoga Telephone Company has replaced its present exchange at this place by one of larger capacity.

SCRANTON, PA.—The lines of the Anthracite Telephone Company have recently been connected with the system of the Consolidated Telephone Company.

APOLLO, PA.—The Apollo Telephone Company will build a new trunk line to Salina and thence to Avonmore.

SPRINGVILLE, PA.—The Peoples Telephone line is building in this place, connecting with other lines above and below.

COLUMBUS, TENN.—The Citizens' Telephone Company has let the contract for building the new line from this city up the Bear Creek Pike to Losea and points beyond. It will also be extended to Hardison's Mill and Rally Hill.

CORNERSVILLE, TENN.—A telephone exchange has been established here and twenty-three instruments connected.

BUDA, TEX.—Work will soon be commenced on a telephone line connecting the inland towns to Buda.

FOREST DEPOT, VA.—Plans are on foot to build a local telephone line from Forest to Perronville, and thence to Lynchburg through the country via Coffee and Boonsboro.

TRADE NOTES.

THE S. H. COUCH CO., INC., 156 Pearl street, Boston, Mass., has just put on the market a new automatic reset intercommunicating telephone. A bulletin is in preparation which will show the several styles. Cuts can be had now, which give a good idea of its superiority over other makes.

THE CONTROLLER COMPANY OF AMERICA, 1061 Monadnock Block, Chicago, has brought out a Controller telephone for local battery and magneto systems. It has no crank, but the drop falls when a nickel or token is deposited in the machine. It is now prepared to furnish controllers for any form of system including the automatic exchanges.

THE CONN. TEL. & ELEC. CO., INC., of Meriden, Conn., is making large shipments of its Selective Telephones. This system is very easy to install and is being used by a large number of prominent exchanges throughout the U. S. and is also being adopted by up-to-date progressive country lines. The company will furnish complete particulars on request.

THE CENTURY TELEPHONE CONSTRUCTION CO., of Buffalo, N. Y., has recently perfected an outside cable terminal head which will prove a boon to telephone exchanges. This cable head is moderate in price, and is mechanically and electrically a great improvement over the existing forms of head. An illustrated booklet will be furnished to interested people upon request.

THE F. BISSELL COMPANY, of Toledo, Ohio, has recently issued Bulletin 20 of its perpetual catalogue. This bulletin describes at length panel boards for power and lighting to meet all conditions. The matter of description is very thoroughly carried out. Exhaustive tables which cover every possible feature as to size, price, and capacity form the most important and larger part of the bulletin. To exchange managers interested in electric lighting this bulletin will prove of inestimable value. It can be secured by request.

THE AMERICAN ELECTRIC TELEPHONE COMPANY has recently supplied the United States Government with switchboard exchange equipments for twelve different points. Of these six are being sent to different stations in Virginia, one to Wyoming, one to New York, three to California, and one to the District of Columbia. This indicates a great activity on the part of the government to adopt the telephone. The company also reports a large amount of activity in its sales department, among the recent shipments being the following: Bronaugh, Mo., one 50-line switchboard; Greenwood, Ind., 200-line switchboard; Sheboygan, Wis., 100-line switchboard; Turner, Kans., 100-line switchboard; Oakwood, Md., 100-line switchboard; Sulphur Springs, Ind., 50-line switchboard; South Omaha, Neb., 200-line switchboard; Lancaster, Mo., 100-line switchboard; Algona, Iowa, 100-line switchboard; Hazlehurst, Ga., 100-line switchboard; Platte, S. D., 100-line switchboard; Barnard, Kans., 100-line switchboard; Cass Lake, Minn., 100-line switchboard.

THE AUTOMATIC ELECTRIC COMPANY, of Chicago, has recently issued three new pamphlets, which deal with its automatic system. One of them is entitled "What they say about the automatic in Grand Rapids," and contains some ninety-four letters from subscribers to the Citizens Telephone Company. This company has over 5,500 telephones in operation today and was the first to have 600 or more telephones in opposition to any Bell company. It has recently placed an order for 1,000 more automatic switches to take care of new business. A photograph is included of this exchange. "What Portland, Me., thinks of the automatic telephone" is the title of another of these pamphlets, which also includes a large number of letters from satisfied users of the automatic in Portland. Portland has an exchange of 3,000, having grown to that size from the initial installation six months ago. The third of these pamphlets forms the annual report of the Citizens Telephone Company of Grand Rapids. This report will be of the greatest interest to those investigating the automatic system, as it furnishes a basis for computing the financial success of the system. These brochures are intended to show, not only the success of the automatic from a practical standpoint, but also the increase in business that can be secured by its use. To all parties interested they will be mailed upon request.

MR. FRANK B. COOK has apparently given the lie to the pessimist who stated that there is nothing new under the sun, for Cook's "Universal" Guy Clamp is without chance for an argument, a radical departure from the accepted types of guy clamps. It really seems remarkable that no one had the temerity (or shall we say originality) to depart from the old idea long ago, but the fact remains that Mr. Cook was the first one to make the leap. The result has been an eye-opener to all users of guy clamps. Cook's "Universal" not only takes any size strand from 3/16 to ½-inch, but when it once takes them it holds them. One of Cook's circulars is a reproduction of the Armour Institute's record of some comparative tests which they made of several well-known types of clamp and the figures are startling. They show that Cook's will hold from two to three times as much of a load as the best of the others. Telephone, telegraph, light and power companies have evidenced their appreciation by sending in big orders. The Home Telephone Co., of Los Angeles, recently placed an order for 5,000, the American Steel & Wire Co., 3,000, the New Long Distance Telephone Co., of Indianapolis, 500, the Buffum Telephone Co., Louisiana, Mo., 300, Sheboygan Telpehone Co., Sheboygan, Mich., 500, Indianapolis Light & Power Co., 8,000, Empire Electric Co., San Diego, Cal., 5,000. A canvass of the supply houses shows that practically all of them are handling Cook's "Universal."

FOR SALE

Advertisements under this head, $1.00 for 25 words or less for each insertion. Prepaid.

WANTED to sell a 200-capacity 160-installed self-restoring drop switchboard of the old Sumter Co.'s make. Board in good working condition. ABBEVILLE TELEPHONE COMPANY, Abbeville, S. C. 258

The 1900 Dry Battery

THE most needed quality is reliability. No one wants a battery that will respond all right for a week or ten days then "suddenly go out of business." Another requirement is that it shall continue "strong" during its life. These two requirements besides many others are characteristics of

1900 BATTERIES

We guarantee them not to freeze, leak or break; we warrant them to work with a strong, steady current during their life (anywhere from six to eighteen months).

They are compact, always ready. They are better than wet batteries—no slop, no repairs, no breakage. Any one can replace a worn out one at a moment's notice. They can be carried anywhere—always ready for instant use.

Write us for our Complete List of Batteries and Telephone Supplies

Bituminized Fiber Conduit
For Underground Construction

Combines the **good features** of other conduits. **Eliminates** the **bad features** existing in many kinds. **Has valuable features** not found in any other ducts. :: ::
Made in 7-foot lengths with male and female joints, making construction very rapid and simple, with consequent low cost. :: :: ::
Alignment is perfect and permanent without tedious care and skill required in laying of butt-joint conduits. Users are astonished by the ease and rapidity with which cables can be drawn in, and this without the slightest scratching or injury to the lead covering thereof.
Made in sizes from 1-inch to 10-inch diameter. ::
Bends of any radius and any angle. :: ::
Write us for further information and prices, stating sizes and quantities required. :: :: ::

American Telephone Practice
By KEMPSTER B. MILLER, M. E.

518 large pages, profusely illustrated with 380 diagrams and cuts of apparatus **$3.00**

A book for the telephone man. It is an encyclopedia of useful information concerning telephony.
It gives complete specifications, enabling you to intelligently order apparatus from manufacturers, and to properly supervise the installation of an exchange, large or small.
It describes in simple language the theory and practice of modern telephony, including circuits, mechanical construction and operation of telephones and switchboards.
A complete description is given of storage batteries, their care and maintenance; of aerial and underground line construction, and, in fact, all the important matters which telephone men need to know.

THE AMERICAN TELEPHONE JOURNAL

What Can be Better Than the Best?

The ultimate in value, that is the general verdict regarding THE AMERICAN TELEPHONE JOURNAL. Here is a letter that brings out that fact once again.

> The AMERICAN TELEPHONE JOURNAL is the best return for a dollar I have ever received. I take pleasure in renewing my subscription for another year. With wishes for its continued success, I am,
>
> Very truly yours,
>
> H. S. KRUM,
>
> 15 West Hollenback Ave.,
>
> Wilkes-Barre, Pa.

When it is remembered that there are 52 issues of The American Telephone Journal a year, and that the cost of a year's subscription is only $1.00, less than the price of a two-cent postage stamp a week, it is not hard to understand why Mr. Krum "takes pleasure" in renewing his subscription for another year.

PAUL LATZKE, President WILLIAM H. McDONOUGH, Editor

Our Selective Central Relay

used on **generator call party lines** at "**central**" does not respond to alternating ringing current.

Relay responds promptly to very weak **direct** current, either pulsating or continuous, **negative** or **positive** as desired.

Relay is simple, only three moving parts.

Relay is adjusted by a hanging weight, similar to the movement of a clock pendulum.

Relay responds to a very small fraction of the current necessary to operate a **bell** or **drop** or ***any* iron core** signal receiving apparatus of similar nature.

Our system operates on Single Wire Ground Lines, Straight Metallic or "Divided Circuit" Metallic Lines.

You can use the **telephones** and **switchboards** you now have.

New telephones for our sytem are supplied by a number of **telephone manufacturers.**

Write for Quotations and Particulars.

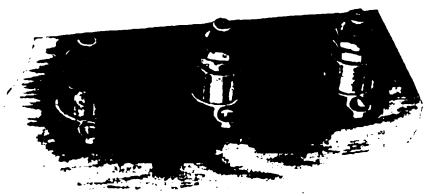
The VERY BEST Telephone

Regardless of Price, Is What Our Customers Demand

PERFECT PARTS FOR THE PERFECT TELEPHONE

SIMPLE

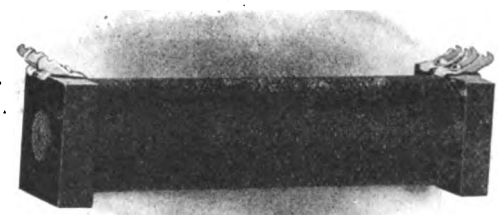


EFFICIENT

Our No. 20 -- ARRESTOR

Machine-made binding posts fitted with two hexagon nuts. Carbons are of good size, thus offering a good discharge surface. They are held under constant pressure between springs, but can be readily removed.

CORRECTLY DESIGNED

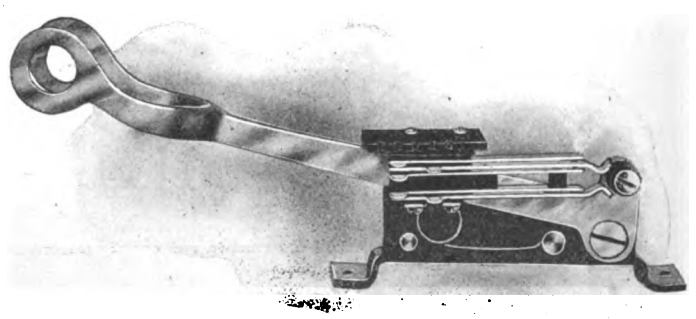


UNIFORM IN RESULTS

Our No. 20-A -- INDUCTION COIL

This coil is used in all our Generator Call telephones. It is manufactured by automatic machinery, thus producing a coil that will give absolutely uniform results. The heads are made of seasoned maple, and are provided with convenient terminal clips. The windings consist of the best grade of copper wire silk insulated.

SELF-CONTAINED



POSITIVE IN ACTION

No. 5 -- HOOKSWITCH

This type of hookswitch operates so satisfactorily that we use it in all of our telephones, simply modifying the mounting plate or frame so it will fit into different styles of telephones.

All this apparatus is fully described in Bulletin No. 11-B

Ericsson Four Party Line System

For simplicity, satisfactory service and good results, this system takes the lead. The line is perfectly balanced. Each subscriber is called without a chance of disturbing the others. One party can call central without disturbing the others on the line. Absolutely non-interfering. Extremely simple to install, to maintain and to operate. Few changes or additions necessary at the switchboards. Ask for particulars with prices, etc.

We supply party line telephones for common return or metallic circuits, either two or four on a line.

We manufacture a large line of telephones, switchboards and specialties.

Our wall or desk, sets, as illustrated, are growing in popular favor because they are so convenient. Price reasonable.

Chicago, Ill.

Replying to yours of recent date, we are more than pleased with your telephones. We have about 75 in use now, and will add more soon. These are used on the same system with two other makes, and are we believe superior to any. At one time, before we connected our rural lines with the switchboards, we had 37 phones on one line, and beyond the confusion of calls, they gave good satisfaction. At present we have 29 phones on one rural line, and they all ring clear and true. I don't know what more could be expected. Not only are we pleased with the telephones, but we are pleased with the courteous treatment your house has accorded us, and hope our business relations may be long continued.

Yours very truly,

Robert Good Secy

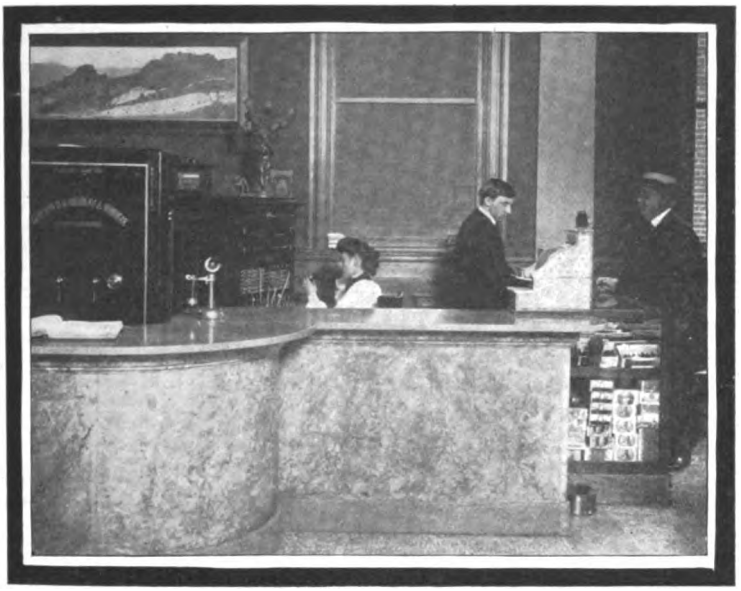
THE PRIVATE BRANCH EXCHANGE AS A BUSINESS BUILDER

ARTICLE I.—THE ECONOMICS OF THE PRIVATE BRANCH EXCHANGE.

By Arthur Vaughan Abbott.



Stromberg-Carlson common battery switchboard installed in the Kingsborough Hotel at Johnstown, N. Y. 110 telephones in use. Board is equipped with lamp signals and receives battery from the exchange. Two trunks to the central office.

IT is currently considered that a private branch exchange is an expensive luxury, but this is far from being the case. On the contrary a private branch exchange is one of the most economical contrivances for the subscriber and simultaneously one of the best of income earners for the telephone company, thus quite nearly solving the old problem of having one's cake and eating it. However, it must not be assumed that the private branch exchange is a universal telephone panacea, for on the contrary, there are some cases in which it would be an extravagance and in others a luxury, for like the punishment and the crime of comic opera fame, the private branch exchange must fit the subscriber, otherwise it would be worse than useless.

Experience shows that telephone traffic is by no means a uniformly flowing stream, but like a mountain torrent is full of all sorts of eddies and whirlpools and cross currents of divers natures which flow in and out among themselves in a most intricate and perplexing fashion. Each subscriber has a particular coterie of conversational correspondents with whom he desires to frequently talk, and it is only on rare occasions that he transmits a message outside of this particular group. It is true that the various groups which are tributary to each subscriber are constantly overlapping each other, causing minor streams of conversation to flow between the groups. But it is astonishing how small these intercommunicating streams are when compared with the normal traffic of the group itself.

This tendency is very strongly emphasized when one comes to consider the traffic which arises between a set of people, who from business or other affiliations are particularly closely united. Take the case of the factory for example, having three or four heads of departments, each containing as many more assistants. Each of the chiefs is likely to wish to communicate with all of the others a score of times or more in the course of each day, and much business is in the nature of brief conversations which can be transacted telephonically with just as great facility as by personal interview.

The value of the telephone as a time saver in the transaction of all such business is almost too trite to need reference. If each man's desk is equipped with a telephone, he may pick up the receiver, gain the ear of desired correspondent and transact his affair in the time which would otherwise be occupied in leaving his chair and going as far as his office door. Over and above the mere saving in time is the increased capacity for work which is secured by use of the telephone. The lifting of the receiver for a telephonic conversation hardly breaks in upon the train of thought which would be hopelessly shattered and dissipated were one to transport himself bodily to the office of the correspondent.

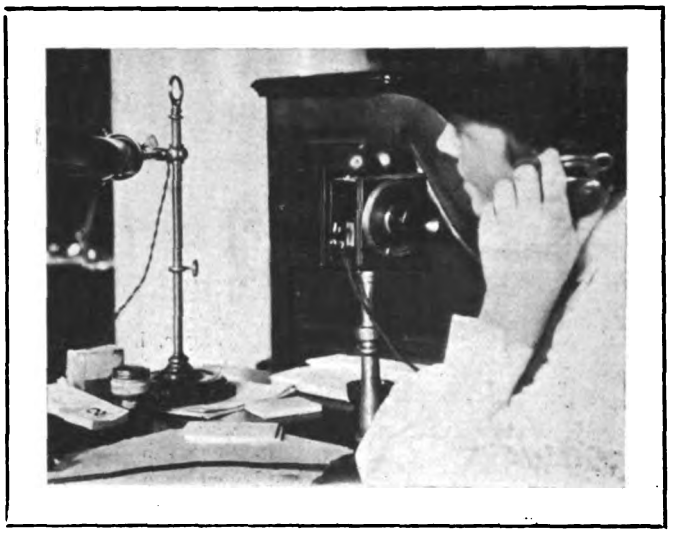
Modern business has been quick to recognize these advantages and there are now few cosmopolitan offices whose every desk is not furnished with a telephone. Now it is easy to see that if each such instrument is connected with the

Stromberg-Carlson switchboard installed in the office of the Blade Printing and Paper Company, Toledo, Ohio. This is one of the largest private branch exchanges in that city.

Digitized by Google

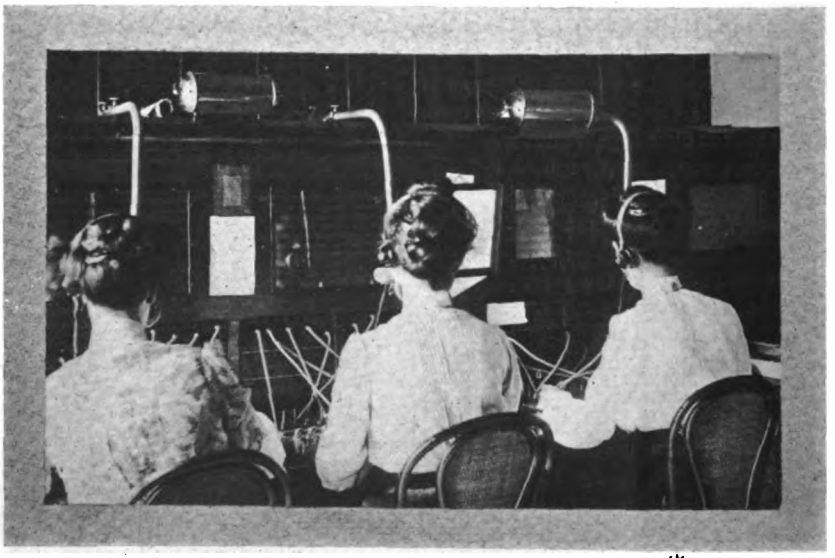
central office, a very large expenditure in the wire plant must be provided, and moreover every message must travel the entire distance to the main exchange and back again to be handled in exactly the same fashion as an ordinary call, even if the two conversants are in adjoining rooms. Of course, this means a very much greater switchboard investment which becomes particularly formidable in the case of multiple jacks.

Operating expense is also decidedly augmented for the traffic of such groups of subscribers is often quite erratic and rises and falls with little regard to the rules and regulations of the normal telephone load line. If the regular telephone line be installed for each employee in a case such as has been described, the bill of the telephone service becomes something enormous. There are few business offices of magnitude that do not require from half a dozen to a dozen instruments while many may need several scores. Based upon the most moderate telephone charges of from $60 to $80 per annum per line, the telephone bill soon rises to the thousands, nor is it possible for the telephone company to mend matters much, because its regular charges are only sufficient to be fairly remunerative after paying operating expenses and interest and depreciation upon its plant investment.



Type of Instrument Used for Interior System of Prudential Insurance Company at Newark, N. J.

The private branch exchange is the solution. A comparatively simple and inexpensive switchboard for small installations is often provided in the shape of a pigeon-hole desk, the necessary jacks and drops or other signals being installed in the space usually occupied by the pigeon-holes, while a portion of the tablet is transformed into an admirable card and key shelf without materially interfering with its usefulness as a desk. The little switchboard is installed in the reception room of the office and then the instruments on each desk connected therewith by lines which, as house wiring, are very short and inexpensive. From the private branch exchange board one or two trunk lines are extended to the central office. These are amply sufficient to take care of all the external traffic, for this is rarely but a few per cent. of the entire traffic which the board daily handles.



Private branch exchange installed in Home offices of the Prudential Insurance Co. at Newark, N. J. At present there are 230 lines installed, of which 66 are for long distance service and 164 are intended for local use in the building only. Eight trunks run to the exchange. Average number of calls daily 2200.

As the board is very simple, no highly trained operating skill is necessary to afford satisfactory service. Indeed, it is common to place the smaller private branch exchange boards in the hands of a stenographer and typewriter or even the office boy, and thus where but few lines are required, office expenses are not at all augmented by the presence of the switchboard. The telephone company can charge an annual rental for the trunk line of about $100, and about $20 per station per annum for each of the telephones and the switchboard.

As a concrete example, consider the case of a ten line board. Upon the single line basis the telephone bill would be, say $800 per annum, which many offices might feel unable to pay. If the private branch exchange be substituted with say two trunk lines, the expense will be about $400 (two trunk lines at $100 = $200 plus 10 stations at $20 = $200). By this means the telephone company has secured $400 annual income which it would otherwise have been unable to get, and it is cultivating the telephone habit which will sooner or later yield a valuable return in the shape of increased demand for service. On the subscriber's part, every desk has its telephone and the internal traffic of the office is as well cared for as if every line ran to the main exchange. Moreover, there are two trunk lines, either or both of which are always at the command of every person in the office without rising from their seats; and all for a rental of half that required on the single line plan.

The example thus instanced is one of very moderate dimensions and it is easy to see that there would be a multitude of cases wherein the saving in annual expense to the subscriber and the economy in the installation cost and operating expense to the telephone company would be vastly increased and the corresponding advantages accruing to both much greater. It is easy to see that as the group of exchanges which the private branch exchanges serves increases, the smaller will be the proportionate cost of installation to the subscriber, because the trunk lines are able to carry a much larger traffic load than individual lines can accommodate without crowding, and consequently relatively fewer trunk lines will be needed to serve a large exchange than would be required for a smaller one, and so the savings in all directions are proportionately increased.

In the preceding calculations, only those advantages that directly accrue from economy in plant and operation have been enumerated. No account has been taken of the increased efficiency which has resulted in the transaction of business and in the saving of much valuable time to those who by means of the diminished expense of traffic service can be accommodated with instruments. It would be impossible to calculate the money saving that thereby results, but experience has universally demonstrated that this saving is really the most important item in the advantages presented by the Private Branch Exchange.

So far the use of the Private Branch Exchange has been largely restricted to the internal advantages which have been presented by enabling members of a single group of subscribers who wish to communicate frequently with each other, but this by no means

Digitized by Google

exhausts the possibilities of this class of service. Indeed, many of the larger stores are beginning to perceive that the Private Branch Exchange may become a valuable adjunct by creating a kind of order clearing house whereby their various customers may order goods telephonically. Formerly telephonic orders have been regarded with a certain species of distrust because there appeared to be no means whereby an order could be checked and its responsibility located, but the private branch exchange affords an opportunity of establishing an order clerk who is able to handle the business in such a manner as to locate the subscriber, book the order which is then through the proper channels, filled and transmitted with a C. O. D. bill. Some of the larger firms report a very material increase in their business by means of the superior facilities that are thus afforded to subscribers to purchase goods with a minimum of inconvenience.

The secrecy which the private branch exchange affords for certain classes of communications is also a point in its favor. Take for example a firm of lawyers, one of the partners may be engaged with a client, while another desires information regarding a point in some other case. To interrupt the conference by calling the first away from his client might be exceedingly injurious, yet it is perfectly possible for the second partner to consult the first over the telephone and obtain the desired information without breaking up the interview and in such a manner as to be sufficiently secret. Thousands of similar instances will readily occur to the reader, particularly cases where financial responsibility, credit standing, or similar items of information are desired.

In the summary of advantages, the position which is held by the Private Branch Exchange operator, the importance which this functionary is gradually assuming, must by no means be forgotten. For now the Private Branch Exchange operator is becoming a kind of a chief confident clerk. She must become thoroughly conversant with the habits, ways, wishes and methods of doing business of each of the principals of her firm. She must know when Mr. Smith is likely to be at the office, whether he happens to be engaged with a particular client or not. She must intuitively guess at the nature of the communications which are sent, and know whether Mr. Jones should be interrupted for a telephone call or whether the caller after giving his name should be requested to defer his message until a subsequent time. Again she transacts numerable items of business of various kinds. She purchase theater tickets, engages sleeping car berths, secures railway transportation, ascertains the time of departure of trains, arranges banking transactions, etc., etc., until to the members of the firm the trained operator becomes one of the most important of employees.

Such are a few of the successes which the Private Branch Exchange has already achieved, but as one of the later developments of telephonic art, it is still barely in its infancy, and in the hands of the skilful traffic manager it becomes a most powerful weapon, one of exceeding elasticity, wherewith it is possible to fit the ends of the most complicated group of subscribers and to afford service which is far superior and far cheaper to any other method now known, redounding equally to the benefit of the telephone company and its patrons.

An understanding of its possibilities is as essential to the operator of the small exchange as it is to the large one, for it may frequently make all the difference between success and failure. This is true particularly in small factory towns, in small educational centers and in summer and winter resorts. It requires only missionary effort to convince the factory owner that the private branch exchange will save its cost half a dozen times in the course of a year, to show the college president in the small city that an intercommunicating telephone system with outside connections, means vastly increased efficiency in his institution, to make it clear to the hotel proprietor in the resort towns that the comfort of his guests will be materially enhanced, at very little cost, by providing a telephone in every room. And all these private branch installations, whether in the small town or larger city will double on themselves, so to speak, for with the simplification of telephonic access, will come a demand for service from new quarters everywhere. The shopper, when she finds that she can reach the department sales people in her favorite store through the private branch exchange, will soon see to it that she has a telephone put into her home. The small tradesman will learn that he can save his time and carfare when, thanks to the private branch exchange, he can reach not only the wholesale house, but directly talk to the desk of the man who books his orders. Consequently he will be willing to subscribe for a telephone when without the private branch exchange to serve his purpose at the other end, the service would not be profitable to him. The list showing the value of the branch exchange as a business builder for the operating company might be extended along the lines almost indefinitely, but enough has been shown here to make clear the general proposition. As the series of articles on this subject proceeds specific cases will be cited that will make clear not alone what *may* be done, but what *has* been done.

J. B. RHODES ON THE NEEDS FOR ORGANIZATION

ON the second day of June, at Columbus, Ohio, the permanent organization of the Ohio Independent Telephone Association was effected.

By the president of the Association a committee was appointed and this committee subdivided the State into nine districts, each district being in charge of a vice-president.

This district, No. 3, comprises the counties of Coshocton, Guernsey, Belmont, Monroe, Noble, Morgan, Meigs, Perry, Gallia, Athens, Washington and Muskingum.

For more thorough and effective organization and work, an auxiliary committee, composed of at least one representative from each county in this district, will be arranged, and by co-operation of these representatives, it is hoped that every Independent telephone company in the district will become a member of the Association, and work as a unit in advancing the welfare of all.

The purposes of this Association cannnot be better expressed than by the language of the Constitution, which reads as follows:

ARTICLE II.

The aim and purpose of this Association is to cement together in a firmer union all Independent non-Bell telephone interests in the State of Ohio, for the purpose of promoting uniformity of operation, maintenance and construction, to protect and defend all Independent Telephone Companies, members of this Association, by moral effort, co-operation and such other available means as may be deemed advisable to prevent the enactment of hostile legislation, promote the enactment and enforcement of laws that will encourage and stimulate development, and any and all other purposes that are deemed to the best interests of the members hereof.

In this connection I wish to say that we have an adversary with a very compact organization, with many millions of capital at its command, and with a desire to heartlessly crush us beyond redemption.

In the past each individual company has in its own way battled with this giant corporation, and the success of this campaign thus far is substantiated by the fact that at the present

Digitized by Google

time in Ohio alone, we have more than 190,000 subscribers, while our adversary has less than 90,000, including the free list, which will quickly leave their ranks should they attempt to charge them for service.

With the many hundreds of hustling business men engaged in the Independent telephone business, their enormous resources and influences, complete success and mastery of the situation will be assured by concerted action of this tremendous power.

We have the full confidence of the public, and by just and fair treatment shall have no difficulty in retaining it.

The necessity for a strong and aggressive Association in Ohio has been particularly apparent during the past year.

While the attempt made by the Bell Company to have legislation enacted whereby all telephone companies would be obliged to connect their exchanges with Bell long distance lines, and the effort at having all Independent telephones removed from the postoffices of this country was frustrated through the efforts of individuals prominently identified with the larger companies—concerted action of all Independent interests in matters of this nature would be promptly available through an organization such as the Ohio Independent Telephone Association, which by its founders has been based upon a plan so broad and comprehensive that it is likely the same plan may be adopted by a National Association.

With such an organization, matters of vital importance to all Independent companies could be properly and promptly handled to the advantage of all. The long distance companies have taken the initial step in their efforts to standardize a system of accounting, and it is hoped that through the co-operation of the Association standardization of equipment as well as methods of handling business in all departments may eventually be worked out, and put into successful operation, thereby very materially reducing the volume of work which is now being done by each Independent company in its endeavor to make monthly settlements with neighboring companies.

The Bell Company has at last begun to realize the unpopularity of their course in the past, and to partially comprehend that the policy of the Independent companies is meeting with unexampled approval and support by the general public. They are therefore not only making an extraordinary effort to regain what they have lost in the cities, but are taking advantage of every available opportunity to demoralize the patronage enjoyed by the Independent companies in the rural districts by offering free county service and many other misleading propositions.

Whether or not they would fulfill such promises is not known in this county, for the reason that the contracts entered into with these people by the Independent companies are just and satisfactory, and they have yet to discover any proper excuse for engaging with the Bell Company upon any terms whatever.

So far as we have been able to ascertain, it is found that in the 3d district we have 47 Independent non-Bell Telephone companies. Blank forms for reporting were sent to each of these companies about the 15th of the present month. As yet, but 18 of these have responded with the necessary information. By computation we find that the number of subscribers served by these 18 companies is 7173, while the Bell Company in the same district has but 2775, slightly in excess of one-third the number of Independent subscribers. If this ratio is maintained throughout the district the total number of Independent telephones will exceed 18,000.

THE TELEPHONE PROBLEM IN LARGE CITIES

By P. Kerr Higgins.

MUCH lately has appeared regarding this problem, but the writers have almost exclusively confined themselves to manual practice.

In view of recent developments in Automatic Telephony, it is interesting to note that this affords the easiest solution to the much-debated problem. In practice it will be long before there will be demand for telephone systems supplying over 100,000 telephones; the Automatic system can handle this number. The present plan is to divide up the city under consideration into ten zones or centers, and in each establish an exchange of 10,000 telephones. Between these exchanges there would be trunks (proportioned as in manual practice). The work of the subscriber is no greater than for a smaller exchange. The first figure of the desired number (e. g., 98343) nine would select exchange No. 9 or numbers in the ninety thousands just as in smaller systems; the thousands are selected now.

In such a system the subscribers' wire mileage is reduced, and hence first cost of the plant is less. The time required to make a call and the mistakes likely to arise are no greater than in a smaller system. It would simply be a standard exchange with its units (switch-boards) scattered and its trunks lengthened. In such a large system some human assistance would be necessary to take care of the many traffic problems, but such is provided by special help, not operators.

The call is made in its simplest form, and no more contacts are necessary than in the systems now giving good satisfaction, and in view of the reduced cost of the plant rates may be reduced.

Another method would be to create a large main trunking exchange so that all trunking would be done automatically. In this way we could establish as many exchanges as we might desire, making them manual central energy and have the operator perform the automatic part. This would simplify the sub-station instruments, retain the intelligence of the operator, give a personal service, relieve the subscriber of the selection of his own numbers and confine the complicated portion of the apparatus to the central office, where it could and would receive the constant attention of experts. There is one drawback to such a system: many calls would have to pass through two operators.

The Automatic is not an experiment; it is a stern reality. There will be found uses for the Manual, but the general practice will be some form of automatic. That there is much room for improvement is true, but the same was also true regarding Central Energy practice, and the next five years will show a wonderful advance along full automatic lines.

USE OF THE TELEPHONE ON RAILROADS IN IOWA.

ONE of the economies practiced by the railroad managers of Iowa is the use of the telephone. The tendency has been to close up many of the small stations because of their unprofitableness, compelling the patrons to go to larger towns. Complaints have been made as to this change of policy, and the railroad commissioners have induced the railroad companies to make use of the telephone to a large extent in providing the facilities for the transaction of business. A telephone line is constructed to the station nearest the one that is without a telegraph operator, and a depot agent is secured who is not an operator. He conveys messages by telephone to the telegraph company and generally transacts all business in this way. The company saves the difference in salary between a telegraph operator and a depot man to handle freight. A great many of these telephone stations have been established in Iowa during the last year at a great saving to the railroad companies.

INDEPENDENT AND BELL IN INDIANA.

THE extent of Independent and Bell systems in Indiana is well illustrated by a comparison of the new directories of the Indianapolis Telephone Company and the Central Union Telephone Company. Number of New Independent long-distance offices in Indiana, 1,322; number of Central Union offices in Indiana, 411; number of offices reached by the New long-distance and not by the Central Union, 1,036; number of offices reached by the Central Union and not by the New long-distance, 125; number of offices common to both, 286.

MEASURED SERVICE HINTS

By H. D. Stroud.

TO the exchange manager the telephone slot machine is a device to mechanically collect the prepayment of telephone charges. This is accomplished by requiring the user to deposit 5, 10 or 25 cents before receiving a desired connection.

The use of the slot machine for telephone service is in its infancy, and its possibilities as a vendor of telephone service are far-reaching. When these possibilities are more familiar to managers, there will, no doubt, be a rapid increase in the use of this method of selling telephone service.

There are a number of such fields for this coin, or, as it is sometimes called, "token" service. Token service is mentioned because where these machines are installed with a guaranteed use by a subscriber, tokens can be sold at any rate, at the discretion of the company.

Assuming that the company desires to offer this service, good plans are open.

Plan 1. Exchange auxiliary or double track service. The astute manager knows that there are many telephones that are busy almost continuously, and the complaints that these lines can never or rarely ever be had are numerous. It is difficult to improve this condition, because the only remedy is to put in more lines to such places, and it has always been a very delicate problem to show a subscriber that he has need for more lines, although he may be the very one who is continually reporting to the manager the fact that his customers complain that he is hard to get. Much tact is needed to convince a subscriber that he hasn't enough telephonic entrances to his office or store to let his customers in without compelling them to wait. A simple remedy is to request the subscriber to allow the company to run another line free of charge, the only consideration being the permission to put the flat rate telephone out of public view and reach and to install a coin instrument in as conspicuous a place as possible. What effect will this have and what compensation will the company get for the investment in the extra line? The best answer is, try it and see. It is evident that such a course would not only be significant of the company's progressiveness in the eyes of its subscribers, but will bar the deadhead from the flat-rate service, leaving these lines free for legitimate use. The coin telephone will not alone be used by the public, but in many cases for the subscriber's service at times when the regular line is busy and a call on the instant is important.

Until the traffic on these secondary lines becomes excessive they can be put on party wires, and as it is one-way service, no bells need be employed. To determine which stations on such a line are to be removed and placed on less busy lines the process is automatic, as the collections will show; for instance, if Smith is on a line with six others and his collector is found to have sixty coins when the other five average only twenty-five, it is plain that he is entitled to be on a less busy line because he is paying better interest on the investment. By removing Smith, room is made for three of the average size users.

Plan 2. Educational service.

The idea of educational service is not a novelty, though few of the Independent companies have given it much thought. It has, however, been a great success in some of the Bell exchanges. Think of the people of Chicago after having been told for years that there was none too much money in furnishing the best grade of telephone service for $175, being offered a telephone for 10 cents per day, the only difference being that in the latter case the company had the right to put ten telephones on the line.

This plan was largely responsible for an increase in the list of subscribers from 23,000 in 1900 to nearly 90,000 in 1904. Residence party-line service was offered for 5 cents per day, a notable reduction from the $60 per year rate charged before the era of the 5-cent slot telephone for residences. Yet these lines pay a neat profit. Nor is this a burden on the subscriber, for a large fraction of the receipts come from the people who before used the service without contributing to its support, but now are made to drop a nickel when they talk.

There is no doubt that if any fairly respectable residence district were canvassed and permission secured to put in a five-cent out-service telephone in every house there would be a big profit to the company at the end of the year.

The one-way or outgoing service telephone with a coin collector attached is probably the most satisfactory form of educational service.

The company hangs the box up on the wall with the permission of the householder, runs in the wire from the nearest junction with any party line, asking for no contract, but simply saying that if it doesn't pay we'll take it out.

This is the first step, the elementary lesson, teaching the people to use the telephone in their own homes. The next step will be a request for bells so that they can be called up. Then is the time to send your solicitor and land them for the best service you can get them to take while they show an interest.

The unprogressive manager remarks that you are taking long chances on an uncertainty, and what are you going to do if your subscriber on probation moves or decides he doesn't want a telephone? There is only one place to which he can move where you can't get him, and that is out of your territory, and his landlord has a direct interest in seeing that you get a new subject to work on.

If he decides after six months' use that he doesn't want a telephone enough to put in a nickel once in a while, you are only in the same condition that confronts any other business man who spends a little money in advertising.

This work could be done in such a way that the line expense would be light and the inside wiring can be shorter than in regular installations when the subscriber has the choice of locations. The instrument is always good for some other place, and need not be large, cumbersome nor unsightly.

Plan 3. Auxiliary residence service, commonly called "kitchen" service, is a field for the profitable employment of the one-way service. Its use is principally for the lady of the kitchen and is most often placed in her sanctum.

Tokens are the best for use in this service, and can be used conveniently, as these instruments are usually installed on a contract with a guarantee of from $3 to $6 per year. The tokens can be sold and payment received when delivered, or can be paid for when collected from the box. The former is doubtless the most satisfactory plan, as payment is secured for service to be rendered; is a plan considered good practice among railroad companies in handling mileage.

It is the writer's belief that the time is near when kitchen telephones on the coin and token plan will be popular, and that progressive grocery houses will have them put in for all customers who order regularly, the grocer agreeing to pay the difference between the actual amount of cash collected and the $3 or $6 per annum, according to the amount guaranteed.

There are many places where there is use for a good deal of telephone service, yet no one to be held responsible for rentals. The coin collector telephone should be used in such places as a measure of protection.

Boarding-house telephones are unprofitable on the flat-rate plan because the service is used by the whole house, while the same places, provided with controllers, would be very profitable to the company and less annoying to the subscriber.

Many thousands of gas meters are now being used that require the deposit of 25 cents before you can light your gas, then when the prepaid amount has been consumed you must put in another quarter. This plan was originally introduced as a measure of

Digitized by Google

protection to the company to cover cases where people would move out and leave their gas bill unpaid. Is it not reasonable to believe that what is good for the gas man is likewise good for the telephone man?

City ordinances sometimes restrict the telephone companies in the amount they can charge for service. This will be found to refer in almost every case to the flat-rate plan.

There is no law in the land that can limit the number of nickels that a telephone company may take out of a machine that is installed without any contract. If there were, the same would hold good for all vending machines.

This opens a new field for the telephone company which started business with rates too low and now find that, with an increase of contracts, they have an increase of expenses out of all proportion at the present time.

The coin telephone can be offered at a lower guarantee than the present rates, and by making the would-be deadhead pay his way an increase in rates can be effected.

AN OPERATOR'S MERIT SYSTEM

By C. H. Judson.

IN 1902 the writer introduced into the operating department of the Twin City Telephone Company at Minneapolis and St. Paul a system looking toward the fixing of operators' wages according to merit, so that the diligent and deserving operator might reap the reward of her labor and the backward or indolent ones might be shown graphically wherein they were amiss in their duties. A sliding scale of wages was adopted in

which three grades of full-fledged "A" board operators appeared. The operators in one of these grades differed from those in another only in their standing as shown by their semi-monthly report cards. A copy of the card is shown above. The card is about 4 by 7 inches in size, and after being completed is shown to the operator whose record is engrossed thereon, and if desired a copy is given to her.

In making the test for record fifty calls are taken, preferably during some fairly busy hour, and of course the operators are totally ignorant of the time when they are being observed for the test. The test is made on an observation desk outside the operating room, and usually by some male employee of the traffic department who can be depended on to procure an accurate record.

A minimum number of points, say 950, is fixed for regular operators below which lies the ground of incompetency, and new operators must reach this point before being placed on the roll of regulars. The operator whose record lies between 950 and 960 receives the minimum regular operator's wages for the month following the test. Operators who record between 960 and 970 receive an additional five per cent. Those between 970 and 980, ten per cent.; those between 980 and 990, twenty per cent., and those whose record goes over 990 receive thirty per cent. above the minimum.

Thus it will be seen that if the minimum wage is $20 for full time "A" operators, those in the fourth grade will receive $21, third grade $23, second grade $25 and first grade $27. While these figures do not represent the wages paid by the company mentioned, they serve to illustrate the system.

As noted on the card, a deduction of ten per cent. is made for each failure. The card may seem rigid in its requirements, and yet in about one hundred operators in one of the cities several continuously kept their record above 995. In addition, points are deducted for unpunctuality, remissness in deportment, appearance or language in the rest room and other matters needing correction.

This system has the advantage of giving the operator an opportunity to classify her shortcomings, and thus bend her energies toward their elimination. The time required to make the tests is not great, and in the writer's opinion is well paid for by the improvement in the service.

"B" operators are tested on a special card and only once a month, as the number of items is smaller and they require less coaching than "A" girls, being usually graduated from among the best of that class.

Besides the graduated wage scale, prizes of $25, $15 and $10 were given to the operators holding the best three records for a period of six months. These prizes are eagerly striven for and are considered money well invested.

The writer claims no credit for originality in the use of the system, the idea having been suggested to him by various traffic men and managers in conversations bearing on the subject of efficient operation. It is an advance over the idea that simply because an operator has worked six months, and is punctual on duty and quick in answering calls, she is entitled to the maximum wage, an idea which seems to prevail to-day in many large exchanges, both Independent and Bell.

BELL SERVICE TO BE DISCONTINUED.

MERCHANTS in Owosso, Mich., have recently signed an agreement whereby they will discontinue the use of the Bell telephone on October 1, and retain the Union telephone only. So emphatic are they in their decision that it is further agreed that in case the Bell Company will not remove telephones they will themselves disconnect them and remove them from the wall. The Union telephone will be the only telephone in their place of business.

The Union Company's exchange is four times as large as the Bell Company's, and is giving a much better service. During the past summer the Union Company largely increased its exchange and added over 250 rural subscribers in the surrounding country as well as a large number in the city, so that now their exchange has over 900 subscribers. On the other hand, the Bell Company has less than 250 subscribers, and with such a small exchange the merchants can get along without the service of the Bell Company entirely.

INDEPENDENT TELEPHONE SECURITIES AS AN INVESTMENT

By C. E. Wilson, *General Manager Keystone Telephone Company, Philadelphia, Pa.*

THERE is about $250,000,000.00 capital invested in Independent telephone properties in the United States, and the Independent companies are operating over 3,000 exchanges and serving about 1,600,000 subscribers. The majority of these are owned in the community where they are operating.

The value of Independent telephone securities is not as well established with bankers and the investing public, as it should be. There are several reasons: First, the banker is ever conservative. Second, the investor usually prefers securities with which he is more or less familiar. Third, the Bell interests, since they found they could not compete on commercial lines, have undertaken to fight the Independent companies by attacking their securities, and for the last five years, have resorted to every form of misrepresentation known to that coterie of 'frenzied financiers.' (With apologies to Lawson.)

Column after column has appeared in the leading daily papers as reading matter ('but placed at advertising rates') announcing the failure of this or that Independent company. A company in the far West would be written up in the Eastern papers or a company in the South in some Northern papers and investigation would invariably prove the stories to be false, but the parties most interested would never hear of it until it was too late to offset the effect by having a retraction printed.

A prominent banker stated to me, a few days ago, that an official of the Bell Company had placed the average cost of maintenance and operation of the various plants controlled by the American Telephone and Telegraph Company at 85% of the gross receipts. My answer was, 'If you have on your desk Poor's Manual, or the Manual of Statistics of 1903, and will look through the reports published, you will see that operating and maintenance are not reported as over 70%, and if you will note the number of subscribers in each case and add about $5.00 per subscriber to the net earnings, you will get nearer the true facts as an operating company has to pay about this amount to the American T. & T. Co. for royalties, which the Independent companies do not have to pay.'

Just as an illustration refer to the Central Union Telephone Company. Its report for 1901 indicated that it has 100,000 telephones; the gross receipts were $2,584,780; net receipts, $611,288.00; the estimated royalties, $500,000.00. On this basis, we estimated operating and maintenance at 56%. On the same basis, the Chicago Telephone Company report for 1902, 65%; The Cincinnati (Bell) Company, 54%; Cumberland Telephone Co., 50%; Hudson River Telephone Co., 54%; N. Y. & N. J. Telephone Company, 58%.

The banker and investor does not seem to understand that these royalties of something over $3.00 per telephone, according to American T. & T. Co.'s report, beside royalties on switchboards, come out of the profits, and are charged up by them as an item of maintenance and operation.

Another investor had had it pointed out to him that the telephone business was a bad investment as they were constantly needing new money and that the plant was never completed and it was necessary to make an additional investment from time to time. My reply was 'That is true, but you are heavily interested in electric lighting, gas, and trolley roads, and I have just been informed that you are making extensions to every one of those plants.' This is a condition that has to be met in every form of public service, and if the plant did not increase with the population, it would denote an unhealthy condition.

I am one who believes that the Independent interests will put the Bell out of business or that the Bell Company will put the Independents out of business. I believe the public demands competition. For years the Western Union Co. attempted to monopolize the telegraph business of the United States, but its patrons, to relieve themselves of the burden of over-charge and bad service, built Independent lines from place to place. Occasionally these lines were bought out with the result that another company sprang up immediately to take its place. This condition of affairs continued until the Postal Company was organized, and we have two great telegraph systems, extending all over the country; the service is very nearly perfect, the charges reasonable and both companies on a profitable basis.

Here in the East our average annual receipts per telephone are about the same as the average received by the Bell Companies. I know of few towns in Pennsylvania that have not both systems.

The fact is that in eight years' time the Independent telephone movement has made such strides that to-day it has more exchanges and more telephones than the Bell Company, which has been in business since 1878, and that approximately $250,000,000 has been invested in constructing 3,000 exchanges and installing approximately 1,600,000 telephones; and that the only point wherein the Bell Company excels is in its capitalization per instrument. I quote from "Telephone Development" by Vinton A. Sears of Boston:

Capitalization per sub. (Bell Co.).....	$417.00
Capitalization per sub. (Independent Co.)...	140.00

This should be convincing proof that this great industry is on a sound financial basis and is here to stay.

The policies of the Independent telephone companies are not dictated by hired officials nor their properties managed by employees who have no further interests than the drawing of salaries. The Independent companies are almost invariably owned right in the community where they are operated. They are financed and managed by business men of standing in the community.

I consider telephone securities just as good an investment and just as safe as trolley roads, gas, water, electric lighting, or any public utility. Some of us may be mistaken part of the time, but we can't all be mistaken all of the time, the Bell Company's statements to the contrary, notwithstanding.

Editor's Note.—Extract from an address made before Penna. State Ind. Tel. Assn. Convention.

NEW L. D. SYSTEM.

DR. ROBERT D. UNGER, of Chicago, claims to have invented a system which solves the problem of submarine telephony. By means of a series of induced currents produced by other induced currents he expects to transmit the voice over a longer distance than possible before. To accomplish this he has invented a cable within which are sectional conductors. These conductors are united by intervening compound induction coils of his own design. The undulating impulses are thus carried from the transmitting to the receiving end of a telephone line by a series of repeating coils.

FROM BOSTON.

THE man from Boston walked with mathematical regularity into the public pay station of one of our large hotels. To the operator in charge he remarked in dulcet tones: "I am desirous of interrogating if not actually maintaining an articulate conversation with a gentleman who possesses directly or indirectly the numerical designation of 2200 Main; will you kindly establish instantaneous telephonical communication with him?" It took ten minutes for the operator to recover.

IMPORTANCE OF INDEPENDENT ORGANIZATION.

WE have been devoting considerable space lately to the movement that has set in for a closer organization among the Independent telephone companies of the United States. In this course we have been guided by the conviction that the most important question in the telephone field at this instant is this matter of perfect, business-like national association. For upward of two years, the editor of this paper has steadily pointed out the need of a change in the methods of the two organizations in the field, the National as well as the Interstate. In the course of this agitation it has been deemed necessary to say some rather unpleasant things, and to incur the displeasure of some of the people who have at times used these associations for their own ends. But while the parties immediately concerned may not have been entirely pleased with our utterances on this subject, the real telephone men, the active operators in the field, have, we know, been entirely of our way of thinking. Their feeling in the matter was voiced in an admirably clear fashion at the recent St. Louis convention in the letter read by Mr. Edward E. Clement, which had been addressed to him by Mr. O. C. Snider, the vice-president and general manager of the Kansas City Home Telephone Company. In this letter Mr. Snider said among other things:

> "I have read your letter with a great deal of interest, and fully coincide with you in your opinion as to the value of a representative National Independent Telephone Association. The associations which have existed in the past have not been successful. This condition has been due to the fact, as you suggest, that irresponsible people have controlled the associations. It is now time for the leading men who are interested in this enterprise to form a strong association, and work for the success of Independent Telephony.
>
> "The public must be taught that the securities of the better Independent telephone plants are good investments. At the present time only those who actually know the value of these securities can be interested.

On the whole, the National Association, as it has been handled in the past, has probably been at greater fault in this matter than the Interstate. At various times, the National has been dominated by a clique of men who were either utterly selfish or conspicuously incompetent. It has been used as a football to be kicked hither and thither. Its machinery, such as it was, has been employed at not infrequent intervals to forward the interests of this group or to thwart the desires of that. At the beginning of its existence, the National Association, weak as it was, undoubtedly accomplished a great deal of good. While in no sense ever representative, it nevertheless proved a valuable machine for the prosecution and defence of the patent suits that involved the very life of the Independent industry. For this service, the men who brought the association into life, should ever be gratefully remembered. But there came a time when its usefulness along these lines was practically at an end. And from that moment it seemed to stand as a bar to the new and important things that were demanded of a National Association that should bring real benefit to the Independent operators. It was out of this condition that the organization of the Interstate Association grew. Unfortunately this association also developed rather into a debating society than into a practical organization which should devote itself to the handling and settlement of those questions that make for the welfare of the industry. The Conventions of both associations have since proved practically barren of results.

WHY THE PRESENT MOVEMENT SHOULD BE SUPPORTED.

Unless all signs fail, the time has finally arrived when we are to see a change, when we may hope for cohesive, sensible, business-like action among the Independent operators. And it is needless to say that THE AMERICAN TELEPHONE JOURNAL will bend all its efforts towards aiding this movement to a successful issue. We firmly believe that the movement which started in Ohio and which has come to be known as the "Ohio Idea," will solve the problem. The Ohio operators, as detailed in our columns during the last two months, went at the work in a systematic manner, and they have effected an organization that already embraces something over 60 per cent. of the Ohio companies. The method of organization was thoroughly representative, and the results already effected are most promising. No better idea of the methods employed in Ohio can be given than is furnished in the address by J. B. Rhodes, delivered recently at Zanesville. Mr. Rhodes is one of the vice-presidents and head of the third district in the Ohio organization, and we deem his remarks of sufficient importance for reproduction in another section of this paper. It is our hope that every telephone operator will read this address, and also read the address of Mr. J. B. Hoge, the new president of the National Association, delivered at St. Louis on September 22d, and published in its entirety in our issue of September 24th. We believe that Mr. Hoge and his associates, elected at the St. Louis Convention, are going about the business of organizing the industry in a way that will at last bring into the field an effective association with which to meet the Bell campaign. It is our belief also that Mr. Hoge and the other officers of this association will be sufficiently broad-minded to solve the most troublesome problem that has heretofore balked the efforts at a comprehensive organization. This problem lies in the antagonisms engendered between the groups surrounding the Interstate and National Associations. While it is true that the Interstate in the past has accomplished no more in the way of practical workmanship than the National, it has at least had broader claim to representative membership. But with the spirit that manifested itself at St. Louis and which resulted in the election of Mr. Hoge to the presidency of the National Association, we think that this condition will pass away and that there lies today as great, or greater, potentiality in the National Association. Only one thing is now necessary to make this potentiality effective, and that is a combination of the two associations. There is no room in the field for two such organizations. Every sane man who is not blinded by his own desires or prejudices must admit that. It is absolutely essential for the existence of a compact working machine that one of the two associations now in the field shall go out of existence. We have assurances from the gentlemen who led in the movement at St. Louis, that every effort will be made to bring about this condition and that no personal considerations will be allowed to stand in the way of coalition. At the forthcoming convention of the Interstate at Chicago in December representatives of the National Association will be in attendance to present a plan which shall bring about this course. It is our hope that no selfish reasons will be allowed to stand in the way of success. If there are we shall hold the men who present these obstacles personally accountable, and all the power of this paper will be used for their elimination.

We are absolutely convinced that the time has come when an effective organization built on business lines can be created, and for our part we do not propose to see this opportunity wasted.

The Telephone in the Courts

Conducted by A. H. McMillan.

Readers are invited to submit questions on any point of Telephone Law. They will be answered and explained on this page.

CITY'S POWER OVER TELEPHONE CHARGES.

Has the city council authority to provide what our charges for service shall be? The city attorney advises that it has under power to "license tax and regulate" telephone companies, and "to regulate and control the use of streets," and the council proposes to adopt a maximum rate for us.

J. B. C.

ALTHOUGH a municipality may be empowered to regulate and control the use of streets, yet this power will not confer upon it authority to regulate telephone charges. So it is held that the city of St. Louis, under the delegation of power to it by the legislature, has no power to fix or limit the rates of charges of telephone companies doing business within its limits. In this case the court said: "If the city had such power, it must be found in a reasonable and fair construction of its charter. We are at a loss to see what this power to regulate the use of streets has to do with the power to fix telephone charges. The power to regulate the charges for telephone service is neither included in nor incidental to the power to regulate the use of streets, and the ordinance cannot be upheld on any such ground." Though the city may have power to "license, tax and regulate" telephone companies, yet it cannot, under such power, regulate the charges for telephone service. City of St. Louis vs. Bell Telep. Co., 96 Mo. 623. 2 Amer. Elec. Cas. 44. State vs. Central Union Telep. Co., 14 Ohio C. C. 273. 7 Ohio Dec. 536. Joyce on Electric Law, section 525.

NOTICE OF TREE TRIMMING.

Before a telephone company trims trees to admit of the passage of its lines, need it give the abutting owner anopportunity to trim them? M.

No such notice is necessary. It was so held in Wyant v. Central Telephone Company, 123 Mich. 51.

ADDITIONAL SERVITUDE IN MICHIGAN.

Does the erection of a telephone line along the highway create an additional servitude upon abutting lands in Michigan? S.

It is not so held. See the above citation.

POLES MUST BE REMOVED.

ATTORNEY GENERAL CUNNEEN of New York has advised State Engineer and Surveyor Van Alstyne that the Hudson River Telephone Co. must remove its poles from their position on the Albany and Schenectady turnpike, where a good roads contract is in process of execution, if the poles interfere with the progress of work.

The attorney general in his opinion holds that the company must remove the poles, and if it fails to do so the highway commissioner may summarily remove them. He reaches that conclusion after a discussion of the legal rights of the parties involved, during which he says the purpose for which a highway is constructed and maintained is that it shall be used for the uninterrupted passage of men, animals and vehicles and afford access to the property of abutting owners, and it has been said that for the purpose of such passage the public have an easement in the whole of the highway where that is necessary; it follows that nothing can be permitted to be maintained within its limits which permanently obstructs public travel and the removal of such obstructions can be compelled.

"I do not mean to be understood that the telephone company has no right to maintain the necessary fixtures to carry its line along a public highway," says Mr. Cunneen, "but the rule established by the authorities is that the highway must be kept free for public travel, and if structures like telephone or telegraph lines are placed thereon they must be so constructed as not to prevent a free and uninterrupted use of the highway for travel by the public. The highway commissioners may, and should by written notice served upon the owners, direct the removal of the poles, and in the event of the failure of the owners to remove them the highway commissioners may, by their own motion, summarily remove them."

USE OF HIGHWAYS.

THE Northwestern and Tri-State Telephone companies are engaged in a war over the use of highways along which the Northwestern's Minnetonka lines run. The Tri-State has attempted to cross the Northwestern lines and the latter company alleges that, in making the crossings the former company has interefered with its wires and placed its own where Northwestern linemen cannot care for their own wires without great inconvenience. The company asserts that the Tri-State has injured the service it gives its lake patrons, and has entered the courts with an application for a permanent injunction to prevent its rival from putting up poles and stringing wires along the Northwestern Company's line from Minneapolis to Willmar, Minn.

END OF TELEPHONE FIGHT.

THE city council of Fremont, Neb., has granted the application of the Fremont Telephone company, the Independent concern, for a new license, and the difficulties between that company and the city, which have been in the courts for seven months, are apparently at an end. Last fall the company tried unsuccessfully to secure an advance of rates from the council, claiming that it could not exist at the franchise rates. The council refused to authorize the increase, and durnig the winter the rates were raised 50 cents a month in excess of the rates authorized by the franchise. Thereupon the council declared the license to use the streets forfeited, and gave the company ninety days in which to remove its poles and wires from the streets.

The company commenced a suit in the district court to restrain the city from proceeding to enforce the forfeiture. On the trial the city was successful. Since then there has been a change of management of the telephone company and more amicable relations established between the city and the company. The company has admitted that its course was ill-advised, and its application for a new license last night received the support of seven of the eight members of the council. The license gives an increase of rates, which, under existing conditions, will admit of the paying off of some of the debts of the company, but is not expected to yield a dividend for some time.

A QUESTION OF RATES.

We have two rates and two different grades of service. One of our subscribers pays the lower rate and insists on getting the special service. He claims that the rate he pays is all we are permitted to charge by statute, but we claim that the statutory rate applies to our ordinary service and not to the extra grade. We cannot afford to furnish the best grade of service at the maximum rate provided by statute. Please advise us as to the law upon this subject. J. Telephone Company.

A STATUTE prescribing the maximum rates to be charged for telephone service, in the absence of any classification of rates, will entitle the applicant for such service to receive the highest grade or class of telephone service, at the rate prescribed. The word "telephone," in a statute prescribing the maximum rental for the use of telephones, will be construed as referring not to a single instrument only, but to all the necessary and usual apparatus and instruments for the ready and convenient reception and transmission of telephonic messages. And such a statute cannot be evaded by supplying a limited service, at the rates designated, and a complete service at an excess rate, but the applicant should be supplied with all the usual exchange connections and facilities. Central Union Telep. Co. v. Beadbury, 106 Ind. 1, 5 N. E. Repr. 721, Am. Elec. Cas. 18. Joyce on Electric Law; section 523.

IN THE OPERATING FIELD.

U. S. AND CUYAHOGA COMPANIES NOT TO BE SOLD.

SPEAKING about the report that the Cuyahoga and United States Telephone Companies were to be sold, President Dickson, in a recent interview, stated that neither of the companies would ever be sold except to strong Independent telephone men. Said Col. Dickson to a representative of *Finance:*

"The situation with regard to the United States is unusually strong, and I will tell you why. The strip of territory which stretches from the Great Lakes to Cincinnati and the Ohio River is the gateway between the great commercial centers of the East and the great commercial West.

"All of the freight destined for the West must pass through Ohio and all of the telegraphing and telephoning must pass through Ohio. This is the territory that is occupied, so far as the Independent telephone people are concerned, exclusively by the United States Telephone Company. It is the vital point in the whole situation, and we believe that we have the very best Independent long distance plant in the United States. We hold the key to the situation and we are not disposed to sell at anything less than a fair price.

"The property, as is well known, is not for sale, but every man will sell when he gets his price, and we will do the same provided the buyer represents strong Independent telephone interests. However, I do not believe there will be a sale of the United States or Cuyahoga Company, and I do believe they will be developed to their full capacity by the Everett-Moore syndicate and will eventually be two of the greatest earners in the telephone business, either Bell or Independent, in the United States."

KANSAS CITY BRINGS SUIT AGAINST THE M. & K. TELEPHONE CO.

PETITIONS have been drawn for suits by Kansas City, Mo., against the Missouri & Kansas Telephone Company, the Western Union Telegraph Company and the Kansas Electric Light Company and other electrical concerns that have not as yet paid the pole and wire tax authorized by the city ordinance. The city has refused to issue any more pole permits to the telephone company until payment is made, and it is stated that the company is starting to string its own wires without permits. As a result the matter has been referred to the legal department of the city.

HOLDS COURT BY TELEPHONE.

JUDGE LEWIS B. HIBBARD, of Highland Park, thinks he has found a new and convenient way of holding justice court in certain cases where the charge is not so serious and the accused is a reliable party. It has just been successfully tried there. A complaint was filed against a certain person. The justice sent him a note and the person called up by telephone. Thereupon the justice convened court, the accused pleaded guilty over the telephone and was assessed a nominal fine, which he promised to pay. Thereupon court adjourned.

MEXICAN TELEPHONE COMPANY MOVES ITS HEADQUARTERS.

RAPID progress is being made by the Mexican Telephone Company in preparing for the change of its offices from Santa Isabel, No. 6½, to Arcos de San Agustin, No. 8, in the City of Mexico. In order to make this change it has been necessary to place a large number of cables, some of which contain as many as 240 wires. All material necessary for the change has been received, including the switchboard of an improved type.

The new building, which the company is to occupy, is commodious and well suited for the purposes for which it is to be employed. The company will transfer there its shops for the manufacture and repair of its telephone apparatus, as well as its general offices. The room to be occupied by the switchboard is large and well lighted and arranged for the increase which may be expected in a considerable number of years. At present the company has about 1,800 telephones in use. Preparations are also to be made for two large retiring rooms for the operators, where accommodations will be provided for the taking of lunch, making coffee, etc.

The switchboard which is now being installed in the new office is what is known as the branch terminal, self-restoring drop switchboard, which has many advantages over that now in use.

EXTENSIONS TO SYSTEM AT BOWLING GREEN, KY.

C. A. EDWARDS, of Huntington, Ind., one of the promoters of the Home Telephone Company in Bowling Green, Kentucky, recently visited that city to look over the telephone plant. He visited Woodburn, going through the country where the Home Company is expecting to put in an exchange. While at Bowling Green he visited Smith's Grove and Morgantown and other places with a view to extending the system in those vicinities and looking after the interests of the company he represented. The line to Woodburn has already been started and will be completed at an early date. The Home Company is making every effort to put in as complete a telephone system in Warren County as is to be found in the country. It now has over 600 telephones in Bowling Green besides the connections that can be had with other places.

INDEPENDENT VS. MUNICIPAL IN BRANTFORD, ONT.

THE determination as to whether an Independent Telephone Company shall be allowed a franchise or that the municipal authorities shall install a competitive system at Brantford, Ont., is still unsettled. From the investigation made by the city of Ottawa it would appear that it would be preferable to grant a franchise to an Independent company. The reason can best be explained by a statement of facts. It would necessitate an expenditure of from $35,000 to $40,000. This would mean either negotiating a loan or else investing just so much of the city's funds which could be used to other purposes.

The general trend of public opinion seems to be toward the granting of an Independent franchise, since if it is decided at any future time to secure the property, this could be done much easier than by constructing a system at the present time.

A NEW SYSTEM.

GREGORIO PANSA, an Italian engineer, is the inventor of an apparatus which fulfils the three-fold functions of wireless telegraph, wireless telephone and wireless autographic postal service. He has been experimenting with his invention for two years at Cassino, near Rome, and is at present in negotiation with both the French and United States governments and with an English telegraph company with a view to selling it.

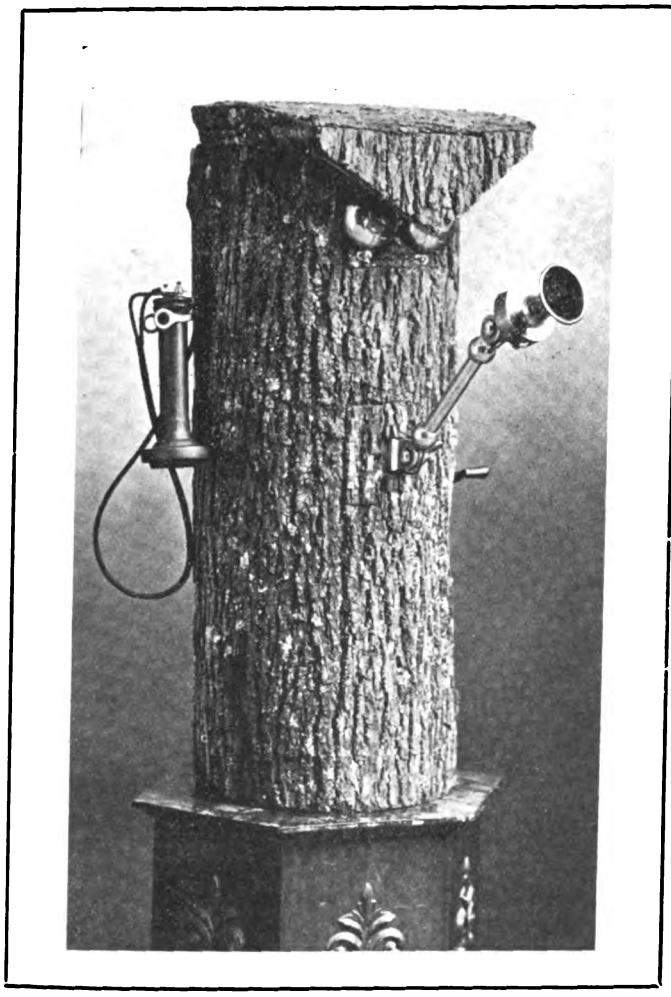
Pansa says that his apparatus secures absolute secrecy for wireless telegraph messages which cannot be tapped en route. The most astonishing feature of the new system, however, is its postal

Digitized by Google

service. All that is necessary is to write with special ink on chemically prepared paper and drop the letter into an aperture in the machine and the apparatus does the rest. A fac-simile autograph copy of a letter from New York can be delivered in London in the time it takes to send an ordinary cablegram. Pansa says that telephoning between New York and London presents no difficulties with the new system.

PATIENCE AND PERSEVERANCE.

SOME people are endowed with a much larger amount of patience and perseverance than others. Mr. E. A. Peters, superintendent of the Buchanan County, Iowa, Telephone System is an illustration at point. He conceived the idea of constructing a telephone in the most unique manner. During his spare time a section of a tree was hollowed out and in and upon it were mounted the various pieces of apparatus which go to make



a telephone. The result of his ingeniousness is shown in the accompanying illustration which gives evidence of a large amount of initiative in design and mechanical arrangement.

Mr. Peters has been engaged in the telephone business for the past six years, two of which were spent in a factory and the remainder in exchange work and operation in the Independent field of northeastern Iowa. The faculty of taking pains and working diligently has placed him in a position in which all who have met him are of the opinion that he is a thorough telephone manager.

TELEPHONE CONNECTIONS ON TRAINS.

THE St. Louis, St. Charles & Western Railroad will be the first western road to adopt the use of telephones for the convenience of its passengers on trains. An agreement has been entered into with the American Car Telephone Company by which the line of the road will be equipped with a telephone system by means of which passengers on the trains, while traveling, will be in direct communication with St. Louis. The device follows somewhat the plan of an overhead trolley.

The Pennsylvania Company is now running through Ohio, for the special benefit of Pittsburg wholesalers, a passenger train which has a most unusual equipment. There is a telephone in every seat, and as soon as the train arrives at a considerable city, where a stop of some time is to be made, connection with long-distance telephone lines is made, so that the occupants may talk with their home houses.

NEW TOLL LINES IN NEBRASKA.

THE Western Telephone Company, recently incorporated at Lincoln, Neb., announce that they will build at once toll lines in all directions from Lincoln. They have already completed their line to Palmyra to connect with the Nebraska City lines, and are now at work on lines south to Beatrice and west to Crete and Kearney. They also intend building north to Columbus. They are offering a very liberal contract to exchange managers.

SUCCESS OF MINNESOTA COMPANY.

THE Citizens' Telephone Company of Mankato, Minn., is meeting with very good success, and during the six years of its life has built over 25 miles of toll lines and a like distance of rural lines. The company has also opened up connection with a number of farmer lines throughout the State. The present developments of the company include connections at Worthington with the Sioux Falls line now being erected at Yanktown, Mitchell and Sioux City.

CALHOUN COUNTY TELEPHONE CO. OPENS UP NEW TERRITORY.

THE Calhoun County Telephone Company has opened up a new territory recently that it has never reached before in southern Michigan and northern Indiana in addition to the regular toll points. This means an addition of between two and three thousand new subscribers. The new points reached in Michigan are Fairfax, Nottawa, White Pigeon, Constantine, Coldwater, Quincy, Batavia, Bethel, Matteson, Girard; and in Indiana, Orland, Angola, La Grange, Rome City, Kendallville, Goshen, Elkhart, South Bend, Mishawaka, Fort Wayne, Albion, Lafayette, Butler.

These additions will be in the new directory which is now in the printer's hands and will be ready for distribution about the first of November.

OHIO TOLL LINE COMPANY INCREASES DIVIDEND.

AT the semi-annual meeting of the Northwestern Ohio Telephone Toll Line Company a dividend of five per cent. was declared, an increase of one per cent. over the dividend formerly paid. The company is doing an excellent business. There is very little of the stock on the market and it is held around 40. The company has outstanding $40,000 bonds, and besides paying a dividend of four per cent. on the stock, retired a $1,000 bond last year. This is a Barber & Brailey enterprise, with James E. Brailey president and Charles Peckham secretary.

TELEPHONE SYSTEM IN A PENITENTIARY.

A COMPLETE telephone system connecting every department of the penitentiary with every other part, and putting every guard in the institution within instant communication with the office of the warden and with every other guard on duty, is an innovation in the penitentiary at Salt Lake City, Utah.

The telephone system is simple. There is a call box in every ward and in every watch tower, so that in case anything goes wrong in any department of the prison at any time, day or night, it is but the work of a moment for the guard to communicate directly with the main office, or call for help from any other department of the prison, and all this can be done quietly without turning in a general alarm.

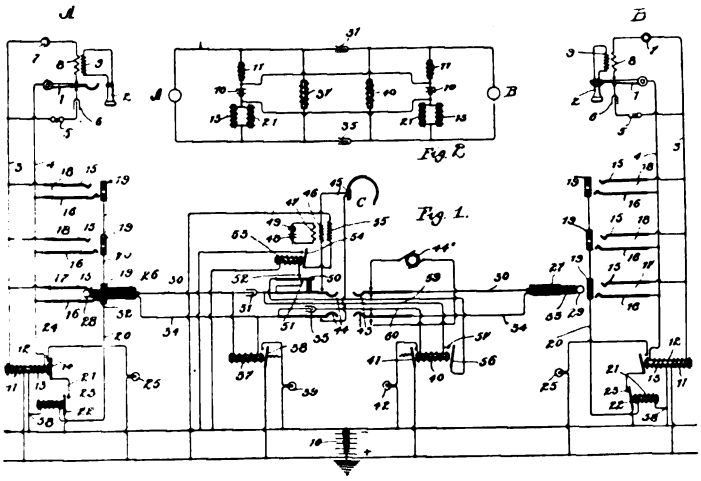
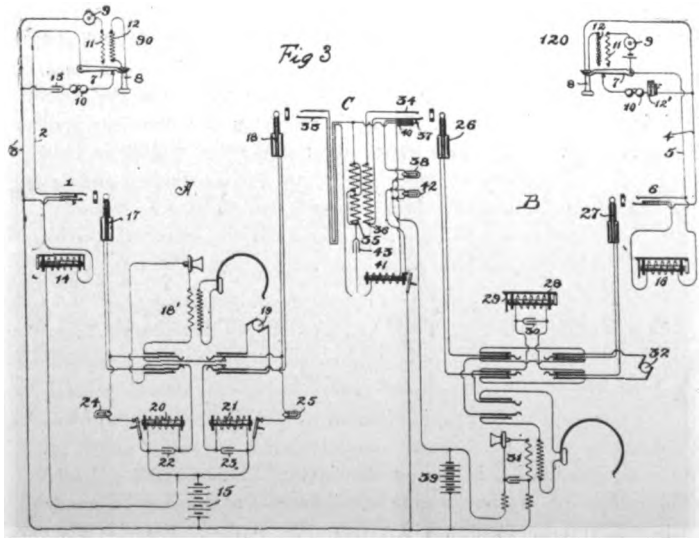
TELEPHONE PATENTS

TELEPHONE EXCHANGE SYSTEM.

W. M. Davis, of Chicago, Ill., patents (Nos. 770,268 and 770,269) and assigns to the Stromberg-Carlson Telephone Manufacturing Company two common battery exchange systems. Patent No. 770,269 relates to a general system for operating common battery exchanges. The essential features are shown in the accompanying illustrations, Figs. 1 and 2. The operation of this circuit is as follows in which *A* and *B* are subscribers'



sub-stations and *C* is the central office. When the hook switch is raised there is a circuit from the positive pole of the battery *10* through the winding *11* of the line relay *12*, to the substation, then to winding *13* of line relay *12* and back to the negative pole of the battery. The relay is thus excited and closes contact *14* of illuminating signal lamp *25*, the circuit of which passes through the contact *23* of the cut-off relay *21*. When the plug *26* is inserted in the jack *17*, it closes the circuit of the cut-off relay *21* in parallel with a circuit through winding *13* of the line relay *12*. The cut-off relay is then excited, its armature attracted, contact *23* opened and the lamp *25* extinguished. The supervisory signal *37* is controlled by a circuit extending from the positive pole battery *10* through winding *11* of relay *12*, thence to spring *17* of the jack, thence



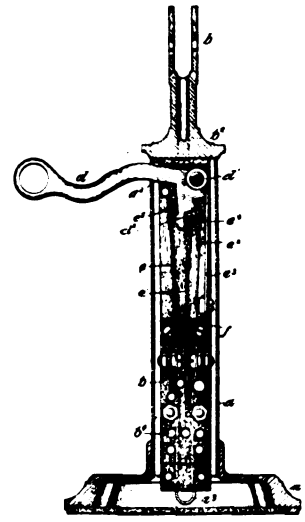
to conductor *30* through the relay *37* to conductor *34*, thence to conductor *20* to cut-off relay *58* to the battery. The test is provided by means of a special test relay *53*.

This patent is a voluminous one, containing 64 claims that specify many interesting features, so that the reader who is interested in telephone circuits would do well to procure an original copy.

In Patent No. 770,268 Mr. Davis discloses a system particularly adapted for operating in connection with toll boards. The circuit is shown in Fig. 3, in which 90 represents a common battery subscriber. The chief features in this circuit are the double supervisory lamps *38* and *42*, which are controlled by the relay *41* in such a manner as to give the operator complete knowledge of the wishes of the subscriber. The circuit is so easily traced from the drawing that further explanation is unnecessary.

DESK SET.

C. L. Boyce, of Detroit, Mich., patents (No. 770,157) and assigns to the Western Electric Company, of Chicago, a desk set. The object of this invention is to provide an improved desk set which is accomplished as is shown in the accompanying illustra-



tion. The inventor provides a stem hand *a'* carrying a vertical cap *a*, into which the mechanism of the hookswitch is inserted. This consists of an insulating strip *b*, upon which the mechanism is mounted, and is provided with an insulating block *f*, which carries the various contact springs *e*, *e'*, *e2*, *e3*, *e4*.

SELECTIVE SIGNALING DEVICE.

J. A. Brown, of Blythewood, South Carolina, patents (No. 770,556) an improved selective signaling device. The object of this invention is to provide a mechanism for selective signaling to be used upon series lines adapted for party lines in small towns and villages. The apparatus is intended to be selective and secret. It employs the familiar step by step mechanism, which is actuated by an electromagnet that is under the control of each station. The apparatus is exceedingly complicated, requiring three sheets of drawings for illustration, and we suggest to those interested in this department of telephony to procure a copy of the original patent.

TELEPHONE REGISTER.

G. A. Long, of Hartford, Conn., patents (No. 770,377) a telephone toll register and assigns to Gray Telephone Pay Station Company, of Hartford, Conn. The object of this invention is to provide a register for the measured service telephone. It consists of a kind of cyclometer mechanism, which is operated by a push button. As soon as the operator notifies the calling subscriber that the desired party has been obtained, the subscriber presses the button. This actuates the cyclometer and registers the number and at the same time causes a buzzer to sound and notifies the operator that a call has been registered.

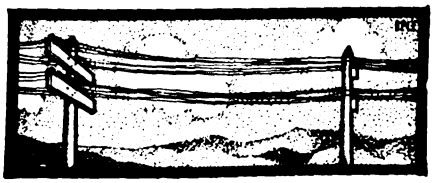
QUERIES

Questions on any subject relating to telephony will be answered on this page.



EXTENSION INSTRUMENT.—(440.)

I have a call to place an extension instrument on a line under the following conditions: It must be so arranged that central can call the main instrument, the main and extension instruments together, or else signal an extension bell. The main and extension instruments are in the house and office, the extension bell is in a mill. Will you please suggest a circuit? There is a return call bell between the office and mill now. Could this be used? G. L.

A circuit which meets the requirements you desire is illustrated in Fig. 440. The switch should be placed near the main instrument, *B*. Its operation is as follows: In the normal position the circuit to the main instrument is closed while the extension instrument and bell are open. Moving the key in the direction of *N* will cause the extension instrument to be bridged across the line, whereas if it is moved toward *S* the main line will be thrown in circuit with the extension bell and the main and extension telephones cut out. The return call bell circuit could be used to signal between the main and extension instruments when it is required to talk between these two points without signaling the exchange.

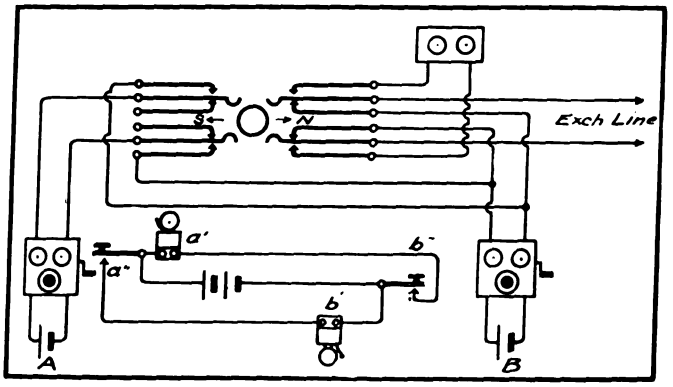


Fig. 440.

COMMON RETURN.—(441.)

We have a common return system, the return wire being No. 12 copper. Can I put too many telephones on the one return or is it better to have them all on one? We have leads running in four directions, all coming into the cable pole separate. So I connected the four together making one return of them all. Was this right or would it have been better to run another No. 12 with the old one, making the return larger? E. L. C.

Replying to your question in regard to the arrangement of telephones upon a common return wire, a No. 12 wire is too small to be advantageously used in any common return. A No. 8, or preferably, a No. 6 is as small as should be employed. It does not make a great deal of difference, under ordinary circumstances, as to how many telephones are placed upon the common return. Usually, the return system is planned to extend in such a manner throughout the town as to reach all subscribers conveniently and then instruments are connected up indiscriminately.

NOISY LINE.—(442.)

Is it necessary to transpose a telephone line more often than four times in a mile? We have a line that runs near an electric lighting circuit and at night times it becomes very noisy. We transposed it four times to the mile but did not seem to get any better results. What is the trouble? S. T.

In all probability your line is grounded or else unbalanced to a great extent. We would suggest your making a thorough test of the circuits for both these troubles. If the line runs very close to the high potential circuit it will be almost impossible to get rid of all the noise without using twisted pair conductors. Telephone lines should not be less than six feet away from a power circuit, nor should they be run on the same pole line. There is always more or less leakage which it is almost impossible to stop, and this would add greatly to your trouble.

INTERCOMMUNICATING SYSTEM.—(443.)

How do I connect three magneto instruments for an intercommunicating system? I want the simplest diagram of connections. L. R.

Fig. 443 illustrates a very simple method of connecting any number of instruments for intercommunicating operations. The wiring is as follows: Run as many wires as there are telephones to be connected and add one wire, which acts as a common return. This common return must be tapped on to each instrument. Run the instrument wires to their respective points upon a circular switch and connect the other line binding posts of the instruments to the switch levers.

In this system it is evident that the switches of the instruments must be kept upon their home points when not in use, else the right party cannot be called as his line is open, and also should one party have his switch on the line of another he would be called when the other party is called. There are several ways to overcome this difficulty which are more or less complicated. In connecting up switches of this type the home point is generally placed to the extreme left, so that it is a simple matter to tell whether the switch is on its home point or not. If you desire further information upon this point we will be pleased to furnish it.

To operate the system move the lever to the line of the party desired and ring in the usual manner. Thus, if No. 1 wished to call No. 3, he would place his lever on No. 3 point of the switch, completing a circuit between the two instruments by means of the common return and the line of No. 3 instrument.

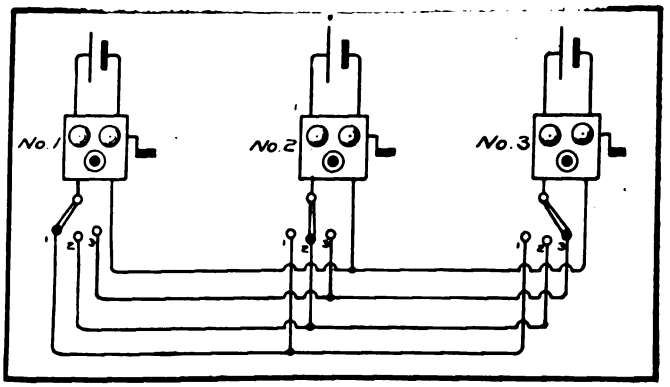

Fig. 443.

AN INNOVATION IN CABLE LAYING.

AN innovation in pulling in cables, it is reported, will be tried by the Sioux City Telephone Company.

Instead of using rods to get the rope through the conduits that is used to pull in the cables, rats will be let loose in the conduits and ferrets sent in after them with cords attached. All the way through the conduit the ferret smells the rat and the rat, if he looks backward, can see the glaring eyes of his arch enemy, which will spur him on to the end of the tube. In this way the line will be drawn through and afterwards a heavy rope attached to it to pull in the cable.

NEW PLANT FOR BELLAIRE, OHIO.

THE Ohio Valley Telephone Company of Bellaire, Ohio, will install a telephone plant of the most approved type. It has purchased the requisite property and asked for bids for a fire-proof building with all modern improvements. The construction work will be the open wireless or all cable construction, using the multiple tap system of distribution. In the business districts underground conduits will be installed. The engineer for the system is Frank B. Hall, who was the engineer for the Utah Independent Telephone Company in Utah.

THE WEEK'S MESSAGES

FINANCIAL.

FARMINGTON, CONN.—The Farmington Telephone Company has declared a semi-annual dividend of 3 per cent.

CHICAGO, ILL.—The directors of the Automatic Electric Company of Chicago declared the regular dividend of 2 per cent. payable November 1st.

HOPEDALE, ILL.—The Farmers Telephone Company has increased its capital stock from $5,000 to $20,000.

VALPARAISO, IND.—The Northwestern Telephone Company of Valparaiso has increased its capital stock from $15,000 to $50,000.

CENTERBURY, OHIO.—The Central Ohio Telephone Company has increased its capital stock from $10,000 to $50,000.

PHILADELPHIA, PA.—It is stated that the Keystone Telephone Company has extended its $1,400,000 loan on the original basis. The company's net earnings for the last nine months ending September of this year, are reported at $257,124, as compared with $158,425 for the corresponding period of last year.

FRANCHISES.

MARYSVILLE, CAL.—Messrs. Dalby & Anderson have approached the city council for a franchise.

REDONDO, CAL.—By a unanimous vote the city council passed an ordinance granting a 50-year franchise to the Home Telephone Company.

ALEXIS, ILL.—The city council has granted a franchise to the Alexis Telephone exchange, which will at once commence the installation of a local system.

COVINGTON, KY.—The Business Men's Club has issued a petition to the councils of various villages in Mill Creek Valley, asking that the Queen City Telephone Company be granted a franchise.

EASTBROOK, ME.—The Eastbrook Telephone Company has asked for a permit to construct lines through certain parts of the town of West Franklin.

ALBION, MICH.—The city council, at a recent meeting, granted a franchise to Charles W. Taylor of Detroit for the construction and operation of an Independent telephone system in this place.

RED WING, MINN.—The council has granted a telephone franchise to T. M. Neill of Red Wing, representing the Moulton interests.

CRETE, NEB.—The Crete Home Telephone Company has applied for a franchise to construct and operate an Independent telephone system.

PERTH AMBOY, N. J.—The city council reconsidered the ordinance granting the Hudson and Middlesex Telephone and Telegraph Company a franchise, which was defeated and passed out by a vote of 4 to 2. W. J. Lansley is general manager of the company, with headquarters at 164 Market street, Newark, and Malcolm McLear is president.

CINCINNATI, OHIO.—At a meeting of the Mutual Creek Valley Business Men's Club, held in Elmwood place, a resolution was passed to petition the councils of the various villages in the valley to grant franchises to the Queen City Telephone Company of Cincinnati.

COLUMBUS, O.—The Jackson County Home Telephone Company has filed an amendment to its charter so that it may extend its lines through Jackson, Pike, Ross, Gallia, Vinton, Lawrence and Scioto counties. Work on the new lines will be begun soon.

SALEM, ORE.—Application for a franchise has been made by W. D. De Varney. Mr. De Varney left for Portland, where he will also ask for a franchise.

DODGEVILLE, WIS.—Thomas Convey, president, William Kramer, secretary, and James Laughlin and P. H. Miess of the Ridgeway Farmers Telephone Company were here recently and appeared before the city council asking for a franchise to construct a line through the State and install a local system.

ELECTIONS.

POMONA, CAL.—At the annual meeting of the stockholders of the local Home Telephone Company the following officers were elected: John Law, president; F. W. Thomas, vice-president; Arthur M. Dole, secretary; C. F. Walker, treasurer, and D. S. Parker, manager.

ARCOLA, ILL.—The stockholders of the Arcola Grain, Coal and Telephone Company at their annual meeting re-elected H. O. Snyder and J. Coonde as directors for a term of three years.

NEW LONDON, IA.—The stockholders of the Henry County Telephone Company have elected the following officers: J. L. Portlock, Green Lee, T. T. Laughlin, W. J. Francy, Frank Smith, J. E. Peterson and James T. Whiting.

WILLIAMSBURG, MASS.—At a meeting of the Williamsburg Telephone Company the following officers were elected: A. S. Hills, president; E. W. Goodhue, vice-president; Stephen Jorgensen, secretary and treasurer. Work on the construction of the plant will be started at once.

CUMBERLAND, MD.—At the annual meeting of the Western Maryland Telephone Company the entire board of directors and officers were re-elected.

HEATH, MASS.—At the annual meeting of the Heath Telephone Company the following officers were elected: W. E. Kinsman, president; H. Newell, clerk and treasurer.

ANNATON, WIS.—The Annaton-Preston Telephone Company has elected the following officers: J. R. Monteith, president; August Lenz, vice-president; William H. Finnegan, secretary and treasurer. It was voted to increase the capital stock by $6,000.

COMBINATIONS.

CLAYTON, ILL.—The Siloam Telephone Company has been sold to B. F. Clark of Perry Springs.

DICKSON, ILL.—The Lee County Telephone Company has sold its exchange and property in Ashton, Franklin Grove, Amboy, Lee Center, Walton and sublet the Farmers Telephone Line.

INDEPENDENCE, MO.—J. S. Hale, principal stockholder of the Home Telephone Company in this city, has sold his Warrensburg and Knobnoster exchanges to the Kinloch Telephone Company of St. Louis.

PULASKI, N. Y.—It is understood that the Ontario Telephone Company of Oswego, N. Y., is negotiating for the purchase of the Black River Telephone's system in Pulaski.

PHILADELPHIA, PA.—The Cumberland Telephone Company and the Winchester Telephone Company, which are operated by the United Telephone and Telegraph Company of this place, have been consolidated.

WAITSBURG, WASH.—A meeting has been called of prominent business men in this vicinity to provide for the extension and improvement of the rural telephone system which has a center in this city. It is probable that various lines will be combined under one management.

NEW COMPANY NOTES.

COLORADO CITY, COL.—An Independent telephone company has been organized here with M. H. Stere of Lincoln, Neb., as general manager. N. B. Hames of Colorado City is president of the company, which claims to have a franchise obtained at a special meeting of the city council of Colorado City.

FINDLAY, ILL.—The East Mutual Telephone Company has been incorporated with a capital stock of $600, by James E. Francisco, Archibald M. Lesley and Curtis Spicer.

CHANDLER, IND.—The Chandler Telephone Company has filed articles of incorporation with the secretary of state with a capital stock of $2,500. The company will build an exchange in Chandler, construct and operate telephone lines throughout Warrick County. J. W. Webb, William M. Gardiner and W. M. Cosler are the incorporators.

GRANTSBURG, IND.—The Temple Telephone Company has been organized here with a capital stock of $5,000. The company proposes to establish a principal exchange in Grantsburg and telephone lines throughout Crawford, Harrison, Perry, Orange and Washington counties. Joseph A. Blevins is president and Samuel H. Miller, secretary of the company.

INDIANAPOLIS, IND.—Articles of incorporation have been filed with the secretary of state by the Western Grove Telephone Company of Hancock County with a capital stock of $320. The directors are: W. F. Thomas, J. C. Hamilton, J. Binford, Sylvester Jessup and E. W. Pusey.

BARNUM, IA.—The Barnum Telephone Company has filed articles of incorporation with a capital stock of $10,000.

CHARITON, IA.—The Richard E. Pedigo Company of Chariton has been incorporated with a capital stock of $10,000, for the purpose of selling territory, granting rights and privileges to sell a certain patented device and improvements thereon known as the Pedigo lightning arrester and telephone cut-out. The officers are J. A. Pennick, president; Richard E. Pedigo, secretary, and W. E. Ashby, treasurer.

MADRID, IA.—J. P. A. Anderson, president of the Madrid Telephone Company has invented a lightning arrester and a company will be organized to manufacture them.

ELDORA, IA.—The Eldora, Rough Woods and Point Pleasant Telephone Company of Eldora has been incorporated with a capital stock of $10,000. The officers are: E. H. Sheldon, president; B. J. Lyman, vice-president; M. D. Kennedy, secretary; F. E. Sprain, treasurer; R. J. Heath, W. H. Wehrman and F. E. Sprain, directors.

WASHINGTON, KAN.—The Washington Telephone Company has been incorporated with a capital stock of $2,500.

WHITE PLAINS, KY.—The White Plains Telephone Company has been incorporated with a capital stock of $2,000. The incorporators are: W. N. Bayly, L. H. Johnson and R. P. Teague.

MANCHESTER, ME.—The Woodland Telephone Company has been organized here to maintain telephone lines in the towns of Manchester, West Gardiner, Litchfield, Farmingdale and the cities of Augusta, Hallowell and Gardiner. $10,000 capital stock. F. S. Collins, president; James T. Collins, treasurer.

GAYLORD, MICH.—About 35 farmers southwest of Gaylord have for some time been talking of a telephone line to Gaylord, and things have so far progressed that it is now in sight. It will connect with a line already built seven miles out from Alba, and from there will extend into Gaylord.

NEWTON, MICH.—The Newton and Leroy Telephone Company, with headquarters at the Newton Center school house, Calhoun county, has been organized. The company will build and maintain a farmer telephone line in Newton and Leroy townships. The stockholders are: E. C. Corey, Union City; J. A. Hurd, Ceresco; Henry Randt, Ceresco; H. W. Flanders, Ceresco; G. D. Spooner, Ceresco.

LIBERTY, MO.—The Missouri Independent Telephone Company has been incorporated with a capital stock of $10,000. The incorporators are: Logan Woodson, Pascal Parker, Samuel H. Woodson.

NEOSHO, MO.—The Granby and Neosho Telephone Company has been incorporated with a capital stock of $3,000 by Edward Haas, R. E. Willard, J. H. Hughes and others.

PLEASANT GREEN, MO.—The Pleasant Green Telephone Company has been organized here. The officers are as follows: Georg Eppright, president; F. Cleland, secretary; William Riddle, treasurer, and J. W. Wall, manager.

HASTINGS, NEB.—The Hastings Independent Telephone Company has filed articles of incorporation with the secretary of state with a capital stock of $30,000, by H. H. Hendon, N. E. Batty, J. N. Lyman, G. F. Keefer and G. H. Platt.

ANDOVER, N. Y.—The Pony Telephone Company has been organized with the following officers: Orange Smith, president; J. W. Jenkins, vice-president; W. W. Pingrey, secretary, and Elmer Kaple, treasurer.

NEW YORK CITY, N. Y.—The Edmonston Telephone Company of New York has been incorporated with a capital stock of $100,000 to manufacture telephone apparatus, by the following directors: Burton Thompson, Daniel M. Miers and John E. Ruston.

Digitized by Google

PATCHIN, N. Y.—The Boston Valley Telephone Company has been incorporated with a capital stock of $2,000 by L. G. R. Whiting, John W. Gasper of Patchin and F. A. Wurtz of Boston, N. Y.

BOTKINS, OHIO.—The Botkins Telephone Company has been organized with a capital stock of $20,000, by S. H. Mendenhall, Charles Eisley, Joseph Miller and others.

RINGWOOD, OKLA.—The Star Telephone Co. has been chartered to build, operate and maintain rural and toll telephone lines in Oklahoma. The incorporators are: W. L. and M. J. Miller and J. H. Huffman, all of Meno.

WINDSOR, ONT.—The Ontario Independent Telephone Co. has been incorporated with a capital of $100,000; head office, Windsor. Directors: C. W. Taylor, J. R. Brooks, J. A. McRae, P. T. Chesley, and A. D. Prosser, all of Detroit.

NEW WILMINGTON, PA.—A telephone company has been organized here and will build a trunk line to New Castle. A company has also been organized at Plain Grove to install a toll line to New Castle by way of Eastbrook.

PERRYSVILLE, PA.—The Perrysville Telephone Company has been organized for the purpose of operating a telephone line between Genesee, New York and West Bingham, Pa.

GRANITEVILLE, S. C.—The Graniteville Telephone Co., capital $3,500, has been chartered to construct telephone lines from this place to Vaucluse, Bath and Clearwater. W. A. Giles, T. H. Rennie and G. L. Knight are the incorporators.

PERSONAL.

FRANK B. HALL, who has been acting as chief engineer for the Utah Independent Telephone Company, has taken charge of the engineering department of the Ohio Valley Telephone Company at Bellaire, Ohio. This will be the twelfth plant having open wireless or all cable construction installed by Mr. Hall.

J. W. LATTIG and C. L. GOODRUM, (formerly superintendent and chief engineer respectively) of the United Telephone and Telegraph Company, have accepted positions with the Stromberg-Carlson Telephone Company.

OLIVER L. TURGEON, manager of the Southern New England Telephone Company in Meriden, has resigned his position.

A. J. BEVERLIN has been appointed manager for the Central Union Telephone Co. at Rock Island to succeed H. H. Unverforth, who goes to the company's headquarters at Indianapolis.

P. J. CUNNINGHAM has been appointed to position of division inspector for the New England Telephone Co. at Lowell, Mass.

JAMES A. WILLIAMSON has been appointed manager of the Mayfield office of the Cumberland Telephone and Telegraph Co.

MISCELLANEOUS.

CHILLICOTHE, OHIO.—The People's Telephone Company's exchange and system have been totally destroyed by fire.

MONTICELLO, IND.—During the recent severe electrical storm the Monticello telephone exchange was burned out.

ONANCOCK, MD.—The Diamond State Telephone exchange, in this city, was damaged by fire to the extent of $500.

HAYDENVILLE, MASS.—An Independent telephone company is being projected here.

KANSAS CITY, MO.—C. E. March, manager of the Independent Telephone Co., of Saginaw, Mich., has been paying this city a visit during the past week.

CAMDEN, N. J.—The Eastern Telephone & Telegraph Company's lines were destroyed by fire recently.

HOMER, OHIO.—The loss to the Independent Telephone Company caused by fire will amount to about $500. The whole telephone service burned out, and will practically have to be rebuilt.

ASHLAND CITY, TENN.—The Clarksville (Tenn.) Home Telephone Co., H. M. Perry, manager, will probably establish an exchange here.

LA CROSSE, WIS.—The Bangor Telephone Company's exchange was destroyed by fire within one hour after being moved into a new location. The fire started from a gasoline lamp which the linemen had been using in their work and which they had left burning when they went outside.

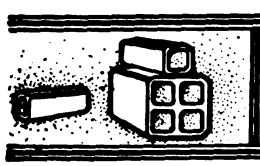
UNDERGROUND.

OTTAWA, CANADA.—The Bell Telephone Company has requested permission to lay conduits on certain streets.

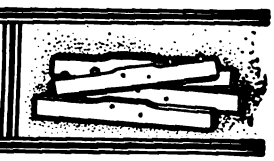
ST. PAUL, MINN.—The city authorities are endeavoring to have the Twin City Telephone Company lay conduits on several streets, taking down its overhead wires.

AMSTERDAM, N. Y.—The Automatic Telephone Company has been given permission to place its wires underground.

UTICA, N. Y.—The Central New York Telephone Company has appropriated $50,000 for the purpose of extending the subway system in Utica.



New Construction in the Field



FRANKLIN, ARK.—The Sharp County Telephone Company will construct a line from Franklin to Melbourne by way of Philadelphia.

PINE BLUFF, ARK.—The Pine Bluff Telephone and Telegraph Company has announced that it will erect a brick building to be used as an office and will lay the majority of its wires underground. It is probable that a new exchange equipment will be installed in case this is done.

MONROE, GA.—W. W. Watkins, manager of the Monroe Telephone exchange, is re-constructing several of its lines.

PECATONICA, ILL.—The Winnebago County Telephone Company will soon install a complete new office equipment in the local exchange.

RUSHVILLE, IND.—The Rushville Telephone Company is spending $7,000 in improvements, which are necessary on account of the company's increased business.

ANGUS, IA.—The Green County Telephone Company will construct a new line to this town.

ELDORA, IA.—The Eldora Mutual Telephone Company is placing a new section of aerial cable to take care of the increased business.

MANSON, IA.—The Mutual Telephone Company will expend $4,000 in improvements to the local exchange.

SHELL ROCK, IA.—The Shell Rock Valley Telephone Company is contemplating the erection of a line from here to Powersville, if the rural business will warrant the maintenance of the line.

ST. JOHN, KAN.—The St. John Telephone Company is replacing its automatic switchboard with a new manual board.

BOWLING GREEN, KY.—The Home Telephone Company is arranging to install exchanges in Woodburn, Smith's Grove, Morgantown and other places.

MACHIAS, ME.—The Washington Telephone Co. has completed the work of constructing the line from Machias to Roque Bluffs.

BATTLE CREEK, MICH.—The Calhoun County Telephone Company has opened up a new territory in South Michigan and North Indiana for toll line service.

CADILLAC, MICH.—The Citizens Telephone Company will build an extension of its line to Boon and Harietta in response to a petition of Cadillac merchants.

GREAT FALLS, MONT.—The Farmers Telephone Company is planning the construction of an Independent line to extend from this city to Black Butte.

HOOPER, NEB.—The Hooper Telephone Company is rapidly extending its lines into all parts of the country in this vicinity.

TILTON, N. H.—The Citizens' Telephone Company is putting in a line to Northfield Center and expects to continue it to Canterbury. The completion of this line will give telephone services to nearly the entire town of Northfield.

BUFFALO, N. Y.—The Inter-Ocean Telephone & Telegraph Co., of Buffalo, N. Y., has announced that a trunk line from Buffalo to Jamestown will be completed by about October 20th. This line is a part of the extensive long distance system of the Inter-Ocean Company, which company has something over 1,000 miles of long distance lines in western New York, and gives service to about 65,000 Independent telephone subscribers.

CANASTOTA, N. Y.—C. J. Wood of Utica, director of the Canastota Telephone Company, was here recently and stated positively that work on the local exchange would be commenced before November 1st.

FORT EDWARD, N. Y.—The Adirondack Telephone Company will at once begin to string wires and install the telephones.

KINGSTON, N. Y.—The Columbus Telephone Company recently stretched a submarine cable 3,400 feet in length across the Hudson river.

WARRENSBURG, N. Y.—The Adirondack Telephone Company will extend its system to North Creek, Stony Creek and Luzerne.

ALICE, OHIO.—A new telephone company has been organized to run a line from Ewington to Buck Eye Furnace.

NORWALK, OHIO.—The Oil Belt Telephone Co., incorporated a few days ago, will build exchanges at Cygnet, Portage and Jerry City, Wood County, with connections and free service with the Independent exchange at Bowling Green. One hundred and fifty miles of wire will be strung and 400 telephones installed.

ALTOONA, PA.—The Altoona and Logan Valley Railway Company will install an Independent telephone system along its right-of-way, utilizing the telegraph poles and wires.

CONESTOGA, PA.—The Conestoga Telephone and Telegraph Company has completed arrangements for the connection of its lines with the Consolidated Telephone Company at Reading. Mr. Hartz of Morgantown has secured 21 subscribers in Birdsboro for his company.

DUBOIS, PA.—The Summerville Telephone Company is preparing to expend between $12,000 and $15,000 in rebuilding its system in Dubois, installing new switchboards, etc.

WALTERBORO, S. C.—The Colleton County Telephone Company is putting up a line between here and Cottageville.

ASHLAND CITY, TENN.—Citizens of this place, at a meeting held recently, formulated a proposition which was forwarded to the Home Telephone Company of Clarksville, asking that company to run lines to that city and establish a local exchange.

TULLAHAMA, TENN.—A new telephone system will be installed here by a home concern.

BUDA, TEX.—Paul Crews will establish a telephone system connecting the inland towns with Buda.

SHERMAN, TEX.—Five carloads of material for the construction of a long-distance Independent telephone line to complete the circuit from Sherman to Texarkana, have arrived. The line has already been completed between Texarkana and Bonham and it is expected that the remainder of the line, from Sherman to Bonham, will be finished before November 1. A line, connecting with the Grayson County Telephone system, will be built also to Gainesville by way of Whitesboro.

PORT ANGELES, WASH.—W. B. Main of Blyn has sold his telephone line to a company which has been organized to develop the country surrounding Blyn.

WHEELING, W. VA.—The Western Va. and Western Telephone Company will extend its line to Newport.

Digitized by Google

TRADE NOTES.

THE CONTROLLER CO. OF AMERICA, 1061 Monadnock Block, Chicago, has issued a novel little booklet, entitled "Something About Tokens." It is well written, and solves some difficult riddles that have bothered the people who believe in measured service, yet do not see how they can make it hitch.

MERRITT AND CO., 1010 Ridge avenue, Philadelphia, Pa., has been awarded contracts for complete installations of its expanded metal lockers. These lockers are the most sanitary in use at the present time and are also the most substantial. The company will be pleased to furnish catalogues and samples of the metal to all parties interested. Correspondence solicited.

FRANK B. COOK, of Chicago, has recently sold to the Monroe County Telephone Company, of Sparta, Wis., one of his well-known type L distributing frames equipped with No. 44 protector. The board has a capacity of 600 pairs, and is now equipped for 300 pairs. The company expects to make additions in the near future, and it will probably not be long before the capacity will have to be increased.

THE AMERICAN ELECTRIC TELEPHONE COMPANY has recently shipped a complete equipment to the Topeka Independent Telephone Co. to be used as a branch exchange in the High School at Topeka. It has also made a recent shipment of a magneto switchboard to Beloit, Kansas, and has also designed and shipped a 500-line capacity Bell Express board, which possesses a very complete arrangement for rendering toll service.

THE MOUNTAIN STATE ELECTRICAL CO., of Wheeling, W. Va., has recently received a number of large orders for the Hall Cable terminals. A large order has been received from the Mutual Telephone Company of Des Moines, Ia., for its special hardware for cable construction. The company reports exceptional business in all its branches. Parties in the market for line and cable construction material should communicate with the company, as it has a number of attractive specialties.

THE CENTURY TELEPHONE CONSTRUCTION CO., of Buffalo, N. Y., has begun active operations in building exchanges at Geneseo, N. Y., for the Geneseo Telephone Company, and at Holley, N. Y., for the Holley Telephone Company. The Century Company has contracted to build the entire outside wire and cable plant, and to build and furnish the central station and substation equipment. The switchboard will be the Century's product in the way of the common battery visual signal.

THE AMERICAN STEEL AND WIRE COMPANY, of Chicago, New York, Denver, Worcester and San Francisco, has issued a descriptive bulletin of wire rope. This is intended to illustrate the various types of wire rope made and for what special purposes they are used. This company manufactures wire rope of every description and also copper cables and strand for electrical purposes. Having sales offices in all the principal cities, it is in an exceptionally good position to fill all orders promptly and to furnish any information required at the shortest possibe notice.

THE DAYTON MANUFACTURING CO., of Dayton, Ohio, has recently issued its third catalogue of Silvey Storage Batteries. The catalogue gives a thorough description of this type of cell, together with a full detail as to sizes, capacities, etc. This firm has recently purchased the entire business and good will of the Columbus Storage Battery Company and is now in an especially good position to furnish all types of cells at the shortest notice. This new catalogue will be furnished upon request and any other information will be cheerfully furnished by the company.

THE BAIRD MANUFACTURING COMPANY, of Chicago, manufacturers of Baird Pay-stations, is selling a large number of their No. 130 Portable Restaurant and Hospital Set Pay-stations. These machines are equipped with an iron back to contain ringer, induction coil, etc., and have a handle plate on the top for carrying about from place to place. This makes a telephone set and Pay-station which is self contained. This machine is meeting with great favor among telephone companies and one large company is constantly buying them in 25 and 50 lots at a time.

THE WESCO SUPPLY CO., of St. Louis, has secured the services of Mr. H. P. Didriksen, who takes charge of its Telephone Department and advertising. Mr. Didriksen's experience in both branches of the work fits him peculiarly for his new position, and the good reputation of "Wesco" telephones, together with the company's prestige in the electrical trade generally, will doubtless prove of much mutual advantage. Mr. J. W. Krueger, who has recently been handling the company's advertising, and who has had charge of the very attractive exhibit of the Wesco Supply Co. at the World's Fair, again takes up his work in Mexico, where the company is developing a very promising business.

THE CONNECTICUT TELEPHONE AND ELECTRIC COMPANY, INC., Meriden, Conn., has placed upon the market two new designs of linemen's portable testing sets. These instruments are styled No. 18 and No. 31, each being the same size, 5½x7½x3¾. No. 18 is designed along the same line as the Bell test sets and contains a generator and polarized buzzer. A two-point switch is included to control the ringing and talking circuits. This instrument is wired for either series or bridging as desired. The No. 31 is a complete telephone and includes the latest types of transmitter, receiver, ringer, and generator. It is designed to work any distance and is used for all kinds of electrical testing and is also in general use by the army and street railway companies. For the latter class of service a plug and cord can be furnished and weatherproof Jack boxes for mounting or poles. Parties interested should write for particulars and bulletins.

THE FRANKEL DISPLAY FIXTURE COMPANY, of New York, has placed upon the market a patent wire testing clip that possesses exceptional merit. This clip is intended to make connection with any line it is desired to test, whether insulated or not. This result is accomplished by means of a pointed stud which is fastened on the inside of the clip and so arranged that when an insulated wire is introduced between the jaws of the clip the point of the stud is forced through the insulation into contact with the conductor. The edges of the jaws are provided with teeth which prevent the wire from slipping. These clips are used by all the largest telephone companies in the country and by the number of repeat orders received are certainly all that is claimed for them. Besides being simple this clip is practical, consequently it is finding a ready market. The company has for distribution a folder which illustrates a number of repeat orders and also gives prices.

FOR SALE

Advertisements under this head, $1.00 for 25 words or less for each insertion. Prepaid.

FOR SALE—Independent magneto plant in Southern town, 3,500 population; 200 drop switchboard; 150 drops in operation; gross annual income $3,500; fixed expense $1,300; in operation five years; no competition; town and plant growing fast; price, $10,000. THE NEW TELEPHONE BOOK

By G. W. WILDER, Ph.D.,
Professor in Telephony
Armour Institute of Technology

This book is strictly up to date and complete in every respect. It deals with all of the ins and outs of telephone apparatus. Profusely illustrated with drawings and half tones. Instruments, switchboard and cord circuits with detailed descriptions, enable anyone to thoroughly understand all the problems met with in telephone practice.

CONTENTS

CHAPTER.		CHAPTER.	
I.	Magnetic Action.	XVI.	Instruments and Instrument Circuits.
II.	The Centimeter-Gram-Second System.	XVII.	Party Lines.
III.	The Electric Current and Magnetism.	XVIII.	Exchange Systems.
IV.	The Solenoid.	XIX.	Switchboard Circuits.
V.	The Production of an Electrical Pressure.	XX.	Switchboard Details.
VI.	Sound.	XXI.	Complete Switchboards.
VII.	Early Forms of Telephony	XXII.	Capacity.
VIII.	The Telephone Receiver.	XXIII.	Common Battery Systems
IX.	The Transmitter.	XXIV.	Selective Party Lines.
X.	Induction.	XXV.	Location of Exchanges and Pole Lines.
XI.	The Induction Coil.	XXVI.	Poles.
XII.	The Magneto Generator.	XXVII.	Wire.
XIII.	Ringers.	XXVIII.	Construction of a Wire Plant.
XIV.	The Generator Shunt.	XXIX.	Cables.
XV.	The Hookswitch.	XXX.	Lightning Protection.
		XXXI.	Line Disturbances.
		XXXII.	Electrical Testing.

Bituminized Fiber Conduit
For Underground Construction

Combines the **good features** of other conduits. **Eliminates** the **bad features** existing in many kinds. **Has valuable features** not found in any other ducts. :: ::
Made in 7-foot lengths with male and female joints, making construction very rapid and simple, with consequent low cost. :: :: ::
Alignment is perfect and permanent without tedious care and skill required in laying of butt-joint conduits. Users are astonished by the ease and rapidity with which cables can be drawn in, and this without the slightest scratching or injury to the lead covering thereof.
Made in sizes from 1-inch to 10-inch diameter. ::
Bends of any radius and any angle. :: ::
Write us for further information and prices, stating sizes and quantities required. :: :: ::

American Telephone Practice
By KEMPSTER B. MILLER, M. E.

518 large pages, profusely illustrated with 380 diagrams and cuts of apparatus **$3.00**

A book for the telephone man. It is an encyclopedia of useful information concerning telephony.
It gives complete specifications, enabling you to intelligently order apparatus from manufacturers, and to properly supervise the installation of an exchange, large or small.
It describes in simple language the theory and practice of modern telephony, including circuits, mechanical construction and operation of telephones and switchboards.
A complete description is given of storage batteries, their care and maintenance; of aerial and underground line construction, and, in fact, all the important matters which telephone men need to know.

THE AMERICAN TELEPHONE JOURNAL

Indispensable to All—That's the Unanimous Verdict

Here is a letter received this week which we believe is fully self-explanatory. It is incidentally a clear statement of a fact that we have known for a long time, and that we have laid much stress on. For reasons which are easily understood, the name of the writer is not given. The letter follows:

> "To-day for the first time I saw your Journal, and although I am an employee of the 'Bell' Company that you 'roast,' I think your paper is invaluable to anyone interested in Telephony, whether actively or not. I want my subscription to start as soon as possible." C. P.,
>
> Baltimore, Md.

It seems to us that when a trade paper thoroughly covers its field, and at the same time is considered "invaluable" by its readers, such a trade paper is the ideal advertising medium for reaching that trade. The American Telephone Journal is such a medium.

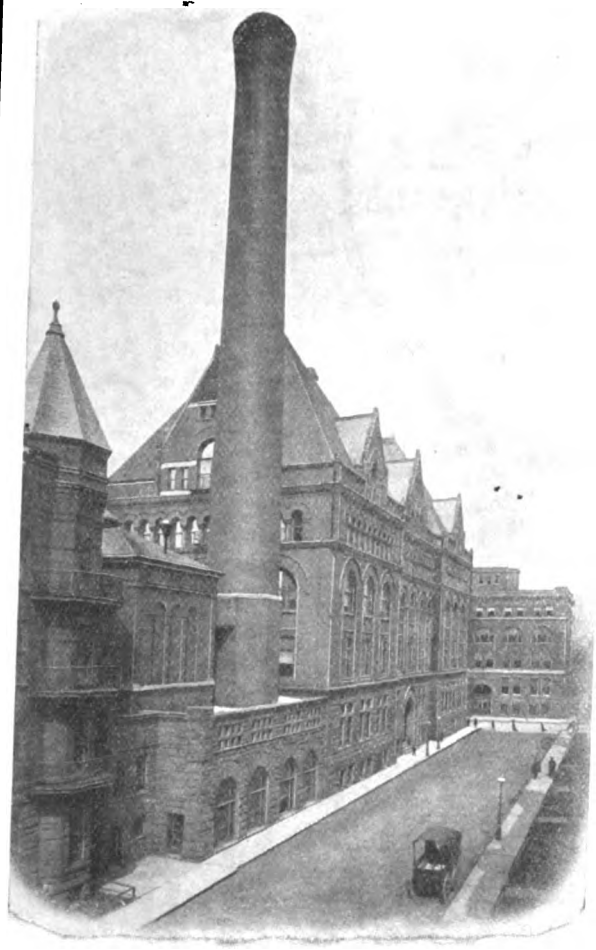
WANTED

Telephone Men Desiring Better Positions



Main Building, Armour Institute of Technology

TO ALL TELEPHONE MEN WHO WANT TO BETTER THEMSELVES

Perhaps you can't afford to quit work and attend a school to secure the technical training and educating that will bring you advancement.

You may be a troubleman, lineman, switchboard-man, inspector or wire chief. Naturally you aspire to be manager of your exchange some day.

You may be manager of a small exchange and have ambitions to manage a large exchange; or possibly you are in charge of a large exchange but wish to become general manager or superintendent.

You are faithful and conscientious in your work. But something is lacking. You can get so far and then you have to see younger men forge ahead of you. You feel the need of technical training to advance. And yet you can't afford to give up your working time.

THE

American School of Correspondence

....at....

Armour Institute of Technology

will solve the problem for you.

Here you can secure the necessary technical education to fit you for the highest positions in the telephone and other electrical industries.

You don't have to stop work,—merely study in spare moments and recite to us by mail. Your recitations have the personal attention of members of the faculty of a widely-known engineering college. Through them many of the advantages of the splendid equipment,—testing laboratories, experimental shops, etc.—of Armour Institute of Technology, representing an endowment of over one million dollars, are brought to you in your own home.

Write to-day for catalogue and full particulars. Tell us what your position is, and what you want to be.

THE PRIVATE BRANCH EXCHANGE AS A BUSINESS BUILDER

ARTICLE II.—AN EXAMPLE FROM PRACTICE.

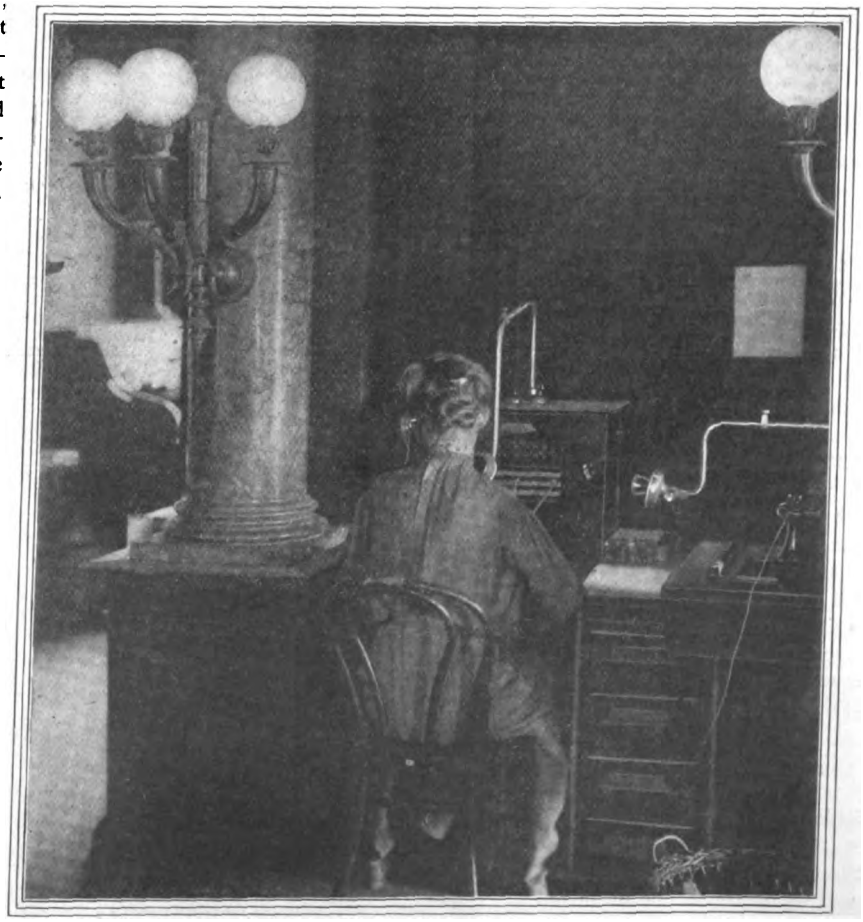
By Robert Louis Jamieson.

Editor's Note.—In the preceding number a few of the salient advantages both to the subscriber and the operator of the private branch exchange were pointed out. It is now our intention to quote some examples from actual practice in order that our readers may gain a further insight into the possibilities of the private branch exchange from the standpoint of the operator, and we here present our readers with an account of the methods used to secure the business in Philadelphia, as detailed by a valued correspondent.

PRIVATE branch exchanges have always been looked upon as a luxury in which only the largest and richest corporations might indulge. But in Philadelphia—the sleepy town, according to its critics—this idea no longer has place. Such systems are held a business necessity by even the smallest firms, factories and corporations. It must not be thought that this reversal of opinion sprang up over night; that it came without concentrated and laborious effort, or that it was due to the demand of Philadelphia business men for private exchanges. Such changes are not effected in a day or a year, nor do they come without hard work on the part of someone. Business men, as a rule, are like the gentlemen from Missouri—"You have got to show them."

Until the Keystone Telephone Company was established in the early part of 1901, the private branch exchange business in Philadelphia was limited and practically unveloped. The Keystone is the largest Independent telephone company, and its field of operation is the greatest at present occupied by an Independent company.

Its promoters, and especially its general manager, early determined to make a special effort for private branch exchange business. Their success in less than four years' time has been truly remarkable, and the financial returns have amply rewarded their persistent efforts. At the present writing, the Keystone Company operates nearly two hundred private branch exchanges, each with at least ten stations, and connected by one trunk or more with one of the six main exchanges.



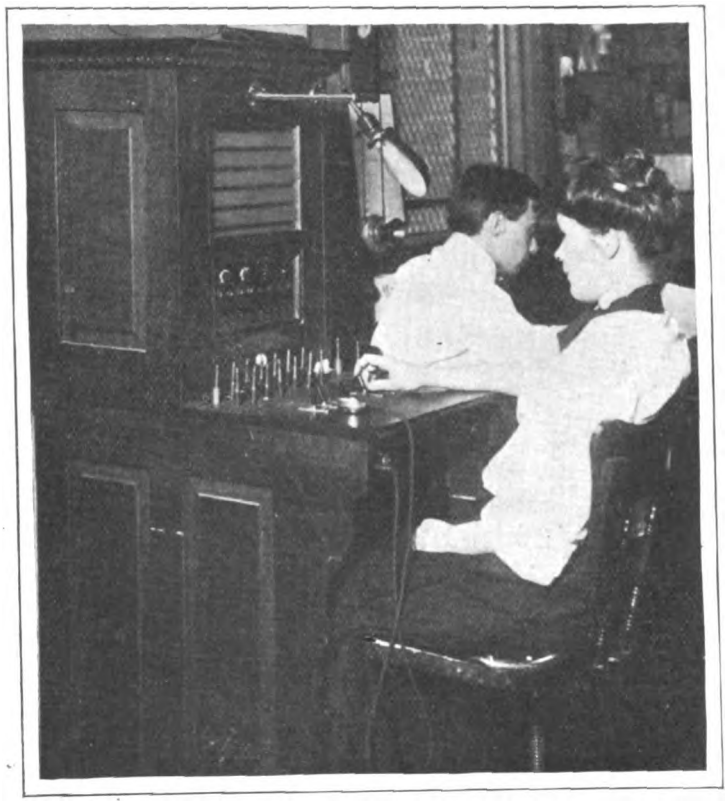
Private Branch Exchange of Keystone Telephone Company, Installed in the Booklover's Library, Philadelphia, Pa. Thirty-eight Stations Installed, ten Cord Circuits, one of which is used for a Special Long-Distance Trunk. Average number of out-going Trunk Calls 138 and incoming 80. This does not Include the Intercommunicating Business of the System.

Its rates for private branch exchange service are as follows: For the first trunk line, the charge is $80 per year; for each additional trunk, 60 per year. $20 to $50 annual rental is charged for a switchboard, according to its size, including the operator's set. Stations are charged for at the rate of $10 per year each. Therefore if a firm has an exchange consisting of switchboard and operaor's set, two trunks and ten stations, the annual income to the Keystone Company is $260. Each additional trunk would bring $60 and each additional telephone $10 annually, and increased rental for a larger board. After the initial installation, we make it our business to see that the equipment is increased to keep pace with the growth of the business.

Although these private branch exchanges bring good returns on the investment to the Keystone Company, the price to the consumer is very reasonable indeed.

Digitized by Google

Stromberg Carlson Central Energy Switchboard Installed by Indianapolis Telephone Co. at Vonegut Hardware Company's office. 18 Stations, 2 Trunks, 8 Cord Circuits.



in comparison with the service rendered. Not only is an unlimited service given, but the prices are much lower than the Bell rates for private branches. The Bell Company charges $36 for switchboard and operator's set, $36 for each trunk line, $12 a year for each station and three cents per call. Thus for a Bell branch consisting of switchboard and operator's set, two trunks, ten stations and say 3,600 calls (which is a fair average for such an installation), the average price would be $336 as against $260, the Keystone charge for an unlimited service with the same equipment.

So much for the financial side of the question, which is, of course, of paramount interest to the telephone company. The subject I have been asked to write on is the methods employed by the Keystone Company in securing private exchange business. I have been asked to treat it with the object in view of pointing out that even the smallest telephone company may go after the private exchange business successfully.

The secret of Keystone growth in this respect undoubtedly lies in two things. The first is advertising, and the second, concentration. The company advertises to let people know that it has this class of service and then it concentrates its forces in an endeavor to convince them that a branch exchange is a necessity in their business. The Keystone way is not to wait for them to ask us about this service. It takes the initiative.

A specific example will probably better illustrate this. The company is now working on one of the largest concerns in Philadelphia. It has a direct line Keystone telephone, but it needs a private branch exchange. To convince the company of this is the task. Because of the location of its one telephone in an obscure corner of the store, it is of practically no use. When the head of one of the hundreds of departments is called, he must be summoned by messenger from a distant part of the building, wasting his time, and entailing an exasperating wait on the part of the patron. Busy calls on this line amount to a tremendous total in a single day. The most expert solicitors have endeavored to show the management the advantages of having a branch exchange. They have pointed out the feature of direct and instantaneous communication between departments which would greatly expedite business, and have shown how a patron of the store could at once get into touch by telephone with any department without loss of time to anyone. They have told them that they are losing money by the waste of their employees' time, and business by the failure of patrons to reach them over the Keystone telephone.

So far all this has been in vain. The organization of the central office will now be brought to bear and the solicitors will be furnished with exact facts and figures.

Every call coming for this store will be turned over to the chief operator. If the patron succeeds in getting the connection, but is forced to wait until the party wanted in the store is called to the telephone, the chief operator will endeavor to secure the caller's name and address, and the nature of his or her business, and, if possible, a statement of the annoyance caused by the delay. By tactful handling, the patron will invariably give the chief operator this information, she sympathizing over the annoyance and explaining for what the information is wanted.

In the case of busy calls, the chief operator takes the name and address of the caller, and in the same manner as above learns what department was wanted and the nature of the business. All these facts are noted on cards. At the end of each day, the cards are taken by the traffic department, the information is condensed and arranged in tabulated form. In this shape it is then turned over to the contract department. Here the information is embodied in a letter to the prospective subscriber. An expert solicitor is sent with the letter to the management. When confronted with information showing the lack of telephone facilities, the length of time patrons of the place are kept waiting, the number of patrons turned away by busy lines, and the remarks of these patrons uncomplimentary to the up-to-dateness of the concern, a contract for a branch exchange is a certainty.

About six months ago, a two-trunk exchange was installed in a large department store. All of the above methods had been

Stromberg Carlson Central Energy Switchboard Installed by Indianapolis Telephone Co. in Office of Schmull & Co. 20 Stations, 3 Trunks, 8 Cord Circuits

Digitized by Google

brought to bear before their contract was finally secured. Now they have eight trunks.

The arguments used by Keystone solicitors are numerous and vary greatly with the different temperaments of the men they approach.

The star man for private branch solicitation has been in this business for twenty years—nearly all of which were spent with the Bell Company. He says the reasonable rates of the Keystone Company and the fact that it gives an unlimited service are strong cards. He points out that a private branch is a time-saver, and consequently saves money. It saves writing many letters, for the telephone is quicker and more satisfactory and a private exchange renders the telephone easy to use. All that is necessary is to ask the private operator to call such and such a number and call you when the party answers. The intercommunicating feature renders the transaction of departmental business between the heads of firms simple and expeditious without either party leaving his office. It does away with messengers to a large extent, and is a great improvement over pneumatic tubes and chutes which have been used to some extent.

A much greater volume of business can be handled in a given time in any office by means of an intercommunicating telephone system. And an intercommunicating system which also gives connection with outside parties is doubly valuable. Much force should be laid on this argument, for if it is strongly put before the prospective purchaser, it will often secure his business. An effective argument is to invite a would-be user to inspect a branch in another house. After seeing what a convenience it is, he usually wants one himself.

A good private branch solicitor must study the requirements of a firm to which he is trying to sell this service, as well as the peculiarities of the individuals composing the firm. Some businesses have many incoming and outgoing calls, but little interior business. Such a concern needs a small switchboard equipped with numerous trunks. Other lines of enterprise have a vast amount of intercommunication, but few incoming or outgoing calls. Two or perhaps one trunk line will suffice for their needs, but they must have a large switchboard and numerous stations. Still another business has few incoming and intercommunicating calls, but a large number of outgoing calls. For these are installed, say one incoming trunk only, as many outgoing trunks as are necessary and a few stations. One such that I recall is that of a public service corporation. They were among the first subscribers to Keystone branches in Philadelphia. At first they had a small system only. They had a large volume of business with their respective branch offices, but few incoming or intermmunicating calls. Endeavors were made to induce them to add several outgoing trunks, but without success. The trunks they had were kept busy with the few incoming calls.

Finally one day a letter was received complaining of the service and saying the lines were kept so busy with incoming calls of no importance that their important outgoing calls could not be put through. They wanted the company to shut out the incoming calls.

This was the cue. A solicitor was sent immediately. He politely told them it was impossible to refuse a connection when their trunks were open. But he showed them that if they had additional trunks for outgoing business alone, it would solve the problem. He brought their order back with him.

There seems no possible reason to my mind why a company operating in a small town cannot secure this paying class of business. Few towns large enough to support a telephone company, but have not several factories, stores or business houses, which could utilize a branch exchange to advantage. The service can be furnished so cheaply that it is within the reach of nearly everyone, and it is an economical and profitable service for the telephone exchange.

It is not alone profitable in itself from a monetary standpoint, but it is a "business builder." Private branch exchange installation creates a demand for new telephones on the part of non-subscribers. When a firm puts in a private branch exchange, it means they will handle more business by telephone. They will handle practically all of their inter-departmental business by telephone. And the increased facilities will enable other firms or individuals to transact business with them freely and quickly.

Firms and individuals that are not subscribers are quick to see they can save time and money and at the same time deal with greater satisfaction with the firm having a branch exchange, should they themselves install a telephone. Women will realize that since the installation of a private exchange in their favorite department store, had they a telephone, they could give their orders to any department without leaving their homes, and without an annoying delay. They will, in all probability, become subscribers.

Smaller firms which have not thought a telephone necessary and which receive orders from the larger ones having branch exchanges, soon come to understand that if they are to keep this business they must be telephone subscribers.

In this way, a private branch serves as a solicitor for increasing a telephone company's subscribers. I consider them the best paying service a company can handle, and well worth special attention. The same arguments and methods used by the Keystone Telephone Company in Philadelphia are applicable with slight modifications by a small company in any part of the country.

COMPETITION IN MISSISSIPPI

By Thomas Marshall.

THE telephone rate war which has been waged for some time in Mississippi will now be fought out before the Mississippi Railroad Commission, which has jurisdiction and supervision of railroad companies. There are a number of Independent telephone systems operating in the State in connection with the Cumberland Telephone Company. These Independent lines are in most cases incorporated and owned by citizens of the State, and they now charge that the Cumberland is waging a war of extermination against them by cutting rates in their territory to such an extent that they will be ultimately driven out of the field.

A petition has been filed with the secretary of the Railroad Commission by the "Mississippi Independent Telephone Association." This petition is signed by the Ctizens' Long Distance Telephone Company, West Point Telephone and Telegraph Company, Memphis Long Distance Telephone Company, Macon Electric Telephone and Water Company, Starkville Telephone and Power Company, Armory and Tupelo Telephone Company, Booneville Telephone Company and J. C. Cavett Telephone Company.

The petition recites that the petitioning companies are members of the Mississippi Independent Telephone Association, and represents to the commission that they are informed and believe that the Cumberland Telephone and Telegraph Company is making to various farmers' lines in sections where said lines are owned by individuals or clubs of individuals the following rates:

"Said Cumberland Telephone Company to run lines one and a half miles from said Cumberland Telephone and Telegraph Company's exchange to connect with said farmers' lines, furnishing telephones to said farmers at the rate of $5 per year. Also, where said farmers own telephones or boxes, the Cumberland Company furnishes transmitters and receivers for said telephones, and gives service at the rate of $2 per year. We further represent that such rates, and the continuation of such rates means the destruction of

Digitized by Google

all Independent telephone companies in the State, and ultimately the power of greater extortion by said company upon the people."

The petition further recites that the Cumberland is extending its lines into all sections of the State, and charges that "the aforesaid rates are made for the purpose of crushing out legitimate competition, which in the end means exhorbitant rates to the people of Mississippi." It is therefore prayed that the commission will investigate the rates, as above set forth, and fix a reasonable maximum and minimum rate, applicable to all rural lines, not to exceed $3 per month, nor less than $1 per month.

THE MAINTENANCE AND OPERATION OF SMALL CENTRAL OFFICES

By A. Dallam O'Brien.

THE small rural central office handling from 50 to 500 lines is not subject to the same conditions that govern the operation of large city offices. The advantages of a specially designed building and cable entrance are lacking, and such companies are unwilling to expend the money necessary to supply the office with all the conveniences and aids to maintenance and operation that can be afforded in larger ones. So the man in charge of an office of this kind must become a creature of expedients and constantly design and discover new schemes whereby he can give the best possible service to subscribers with the least expense. It is the purpose of this article and those which follow to consider some of the more important features of this class of the telephone business and point the way whereby difficulties in operation may be successfully met.

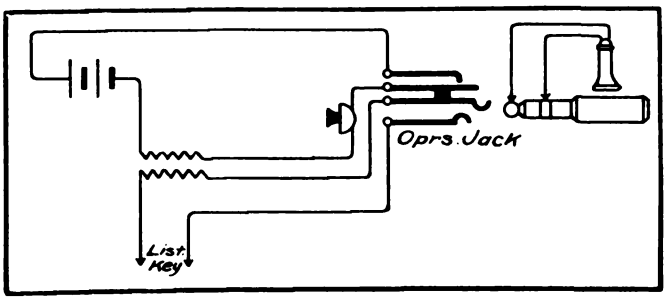


Fig. 1.

One of the most important functions is that performed by the operator's telephone set, for transaction of business is dependent on ready wires for instant service. So it is essential that the wiring be done in a way to court the least possible trouble, and if trouble should arise the circuit must be so arranged as to be readily inspected and the trouble removed. The transmitter batteries are subject to a different set of conditions than those governing the batteries at the substations, as it is customary to arrange the operator's circuit so that the primary circuit is closed during the entire time the operator is at the switchboard. This means that there is a continual flow of current from the battery, and while the actual amount may be very small, yet it is necessary that the transmitter batteries should be able to supply this small current continuously without polarization. Polarization is the formation of a film of hydrogen gas on the negative plate,

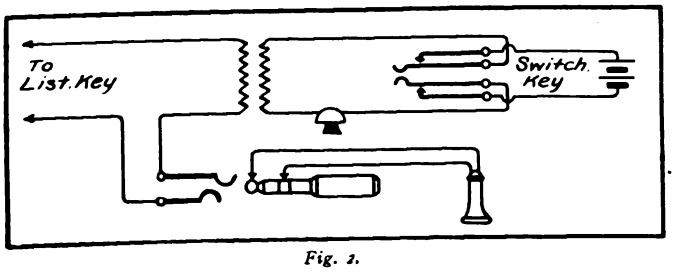

Fig. 2.

that enormously increases in the internal resistance of the battery, which may in time prevent the battery from furnishing the current necessary. In addition the batteries must be of a type which has a low internal resistance.

By referring to Fig. 2 it is evident that when the primary circuit is closed the batteries, transmitter and primary winding of the induction coil constitute a closed circuit. The effect of the voice upon the diaphragm is to cause the transmitter to vary its resistance, and consequently as its resistance changes, the value of the current flowing through the primary circuit changes, the internal resistance of the battery and of the primary winding of the induction coil remaining constant. If, for example, we assume that the battery has an internal resistance of one ohm, the primary of the coil a resistance of ½-ohm, and the transmitter a resistance of 30 ohms, then if the voltage of the battery is 4, the current from Ohm's law $C = \frac{E}{R}$ will be $C = \frac{4}{1 + \frac{1}{2} + 30} = \frac{4}{31\frac{1}{2}}$ .127 amperes. If by talking into the transmitter its resistance is changed or varied so that it is equal to 20 ohms, then the value of the current flowing will be $C = \frac{4}{21\frac{1}{2}} = .186$ amperes, and the difference in current flowing for a change of resistance of 10 ohms in the transmitter is equal to .186 — .127 = .059 amperes. If for comparison we assume the battery to have an internal resistance of 4 ohms, the current flowing under the first condition, as previously stated, will be $C = \frac{4}{34\frac{1}{2}} = .116$ amperes, and with a change of resistance of ten ohms in the transmitter the current will be $C = \frac{4}{24\frac{1}{2}} = .163$ amperes, and the difference in the current flowing in the two cases will be .163 — .116 = .047 amperes.

If we compare the results obtained in these cases, namely, with

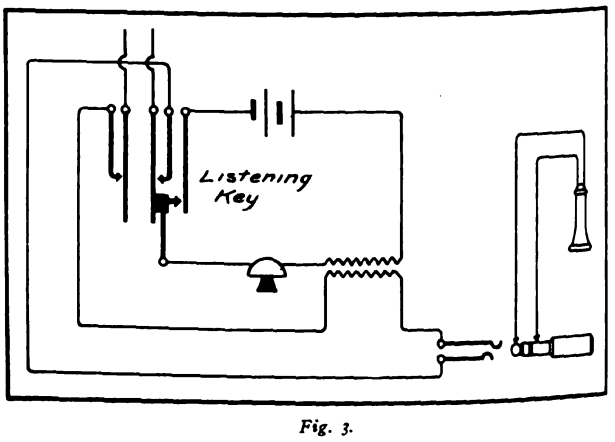

Fig. 3.

a battery having an internal resistance of 1 ohm and another battery having an internal resistance of 4 ohms, it will be seen that in the former a change of resistance of ten ohms in the transmitter caused the current to increase by .059 amperes; while in the latter case the same change only caused an increase in current of .047 amperes. From this it follows that the internal resistance of the battery and the resistance of the leads to the battery should be kept as low as possible in order that the changes of resistance in the transmitter may cause the maximum variations in the flow of current.

The Fuller cell meets these requirements as well as any type.

Digitized by Google

In this battery the positive element is zinc and the negative carbon, while the solution, or electrolyte, is made as follows:

Sodium bicromate ..... 6 oz.
Sulphuric acid ..... 17 oz.
Water ..... 56 oz.

The sodium bichromate is first dissolved in the water, and the acid addded slowly to prevent undue heating. Great care should be taken never to pour the water in the acid, as the acid will fly in all directions and painful and troublesome burns may result. The bichromate of soda acts as a depolarizer in this cell, the oxygen in it uniting with the hydrogen which is liberated at the negative pole, forming water. The batteries should be located in a box or closet as close to the switchboard as possible in order that the leads may be short. Each cell has a voltage of about 2.1, and two cells will answer perfectly for the ordinary magneto transmitter. The leads to the board should be at least as large as No. 12 A. W. G. and well insulated.

It is best to avoid as far as possible all intermediate joints and to bring the leads up the side of the board and terminate them at the binding posts to which the transmitter cords are attached. Every joint, whether soldered or otherwise, is a point of weakness and a source of possible trouble. The secondary leads may be run with No. 16 insulated wire, both to the operator's jack and to the listening keys. The manner in which the battery circuit is closed through the primary coil and the transmitter varies considerably. We herewith show three. In Fig. 1 the method uses the operator's receiver jack as a means of closing the circuit. The jack is provided with two upper springs brought into contact as soon as the receiver plug is inserted, and consequently the primary circuit is closed as long as the plug is so inserted. In Fig. 2 the leads from the battery are wired through a key and by throwing the key are connected through the transmitter and coil. The key may be mounted either on the keyboard or in the face of the board within reach of the operator.

The method at Fig. 3 utilizes a spring, and an extra contact placed on the listening key, and is so arranged that current is being drawn from the battery only during the time that the operator is handling a connection, and consequently there is little waste of power. In any particular case the means of accomplishing this result will depend upon the conditions to be met, but one of the three cases cited will apply in almost any instance. The transmitter battery leads, as well as the wires leading from the cable heads to the switchboard, should be so run that they are not liable to be interfered with by persons walking in the operating room. This can be accomplished by building a trough along the floor back of the board and providing a suitable cover.

HINTS FOR WINDING RELAYS

By Klas Weman.

In telephone practice, a certain type of relay very often is required to perform its functions under very different circumstances and conditions from those for which it was designed. For instance, a relay originally built for a certain voltage, may be required to work at a very different potential. In order to be successful, this relay must be wound to the proper resistance with the proper wire and with the right number of turns.

To calculate by the ampere turns—that is, the product of the current going through the windings of the core and the number of turns—is sometimes less convenient than to use the applied pressure or voltage as a basis.

The electrical efficiency, necessary for carrying out a certain desired function of a relay can be used as a constant for the sensitiveness of any particular type of relay, always remaining the same irrespective of the fators I = amperes, E = volts and R = resistance.

In cases where a great number of relays are placed parallel between the terminals of a large source of current, common for all, as in modern telephone exchanges, thereby giving an almost constant voltage for each individual relay, the voltage is a very suitable factor for determining the proper resistance, dimension of wire and number of turns, when a change is necessary.

For example, let us suppose that the relay is designed to perform its functions at 4 volts, and that the number of turns surrounding the active core are 500, with a resistance of 50 ohms. Now, suppose that this relay must work on 20 volts, it must be rewound, and to find the proper resistance in order to attain the same results at 20 volts, the following formula may be used:

$\frac{E^2}{R}$ = constant

where E = volts
R = resistance in ohms.
E^1 = 20 volts.
R^1 = required resistance.

Then $\frac{E^2}{R} = \frac{E^{1\,2}}{R^1}$; and by substituting values

$$\frac{16}{50} = \frac{400}{R^1};$$

R^1 = 1250 ohms.

This is the proper resistance for the relay at 20 volts, which means that the resistances are inversely proportional to the square of the voltages.

If we now consider the relative number of turns in these cases, we find by using the formula:

$\frac{E}{T}$ = constant;

where E = volts.
T = number of turns.
E^1 = 20 volts
T^1 = number of turns required

Then $\frac{E}{T} = \frac{E^1}{T^1}$; and by substituting values

$$\frac{4}{500} = \frac{20}{T^1};$$

T^1 = 2500;

that the number of turns has to be 2,500, or five times as many, which means that the number of turns are directly proportional to the voltages, provided the wire has the same resistance per turn.

Supposing that the wire used at 4 volts has a diameter of 0.2 millimeters, the proper dimensions of wire for using the same relay at 20 volts can be found from the formula:

E.x A. = constant;

where E = volts
A = area of wire in square millimeters
Then if
E^1 = 20 volts
D = present diameter of wire (0.2 m/m)
D^1 = diameter required

$A^2 = \pi \frac{D^{1\,2}}{4}$ = required area,

we have

$\frac{E \times \pi (D)^2}{4} = \frac{E^1 \times \pi (D^{1\,2})}{4}$; and by substituting values

$$\frac{E \times \pi (0.2)^2}{4} = 20 \times A^1,$$

A^1 = 0.00628, required area of the wire, or,
D^1 = 0.09 m/m diameter.

This is the dimension of the wire to be used when the same relay is required to work on a 20-volt system, which means that the areas are inversely proportional to the voltages.

It will thus be seen that the desired facts necessary for determining the proportions of the relay at different voltages may easily be found by using the voltage as a basis for calculation.

A HANDY INSTRUMENT RECORD

By C. H. Judson.

FIRST of all make a record of every instrument of whatever nature that is received by the company. A good system and one that has proven very satisfactory is to let the storekeeper keep a blotter in which to record the shipments as they come in, entering each instrument by number. The manufacturer's number may be used, but it more satisfactory for the telephone company to number its own apparatus. For this purpose the ordinary adhesive paper numbers may be used, the number, of course, being placed on the inside of the box and *not* on the back.

Style of Instrument_____ No._____

Call No.	Subscriber	Order No.	In	Out

Fig. 1.

In the case of desk sets the manufacturer's number is most satisfactory, since it is difficult to attach a ne wnumber which would be permanent without dissecting the instrument.

The blotter is turned over to the clerk who keeps the record after the shipment is entered and this clerk makes the original entry on the card shown in Fig. 1. This is an ordinary 3 x 5 card and is kept by numbers, with a guide between every one hundred cards. It is immaterial whether each kind of instrument be numbered from 1 up or whether a certain lot of numbers be previously assigned to each variety, but it will be found more convenient to give all desk sets numbers differing from those used for wall telephones, and all central energy instruments numbers different from generator call sets.

After the clerk has entered on the cards the numbers and style of instruments and the date received, the card is filed in the regular drawer for unused instrument record cards.

The storekeeper has on hand a supply of tags of a form shown in Fig. 2, and one is attached to each instrument after having the number and date received recorded on it. This tag may be blue in color to designate an instrument in good order as distinguished from instruments requiring testing or overhauling, for which a red tag is used. As the instruments are issued for installation the installer taking it signs his name on the last line of the tag, the order number and date being filled in by the storekeeper or whoever does the issuing. The cards are sent each day to the clerk mentioned above, who retains it until the installation order comes to him after completion, and after comparing to see that numbers correspond and to get the subscriber's call number and name the data is entered on the instrument record card.

When an instrument is removed it is returned to the storekeeper or the shop and a red tag (Fig. 3) is attached to it and the number and date received is recorded thereon. The instrument is tested, and if no repairs are required the facts are entered on the card, and it is sent to the storeroom where the storekeeper receipts for it on the card, and at the close of each day the shopman turns all tags so signed over to the instrument clerk. This clerk then removes the card from the shop drawer and puts it into the storeroom drawer to be used again as soon as the instrument is again installed. It is advisable for the clerk to remove the card from the subscriber's drawer as soon as the take out order passes him and put it into the shop drawer. Thus he will have all telephones, bells, etc., in the shop in one drawer, all in the storeroom in another, and all in use in others.

No telephone, or any other piece of apparatus, should be taken out without being taken to the storeroom or shop. No instrument should be taken out and reinstalled by a wireman holding two orders, one to take out one subscriber and another to install another. Every telephone should be brought to the office for inspection before being reissued.

Every piece of apparatus in the shop or storeroom should bear a red or blue tag. The shop man will, of course, keep his own shop records of work done on each instrument, as the tag is not intended for this purpose.

The record clerk goes over his shop cards frequently, and if

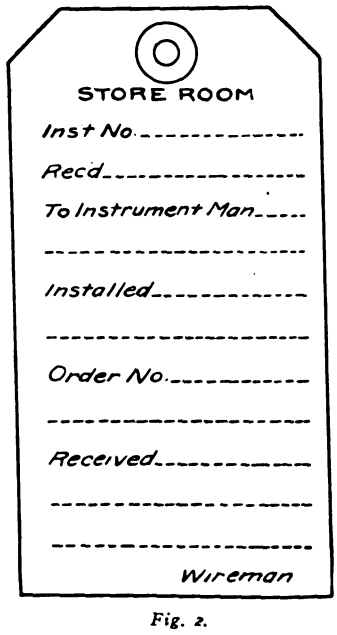

Fig. 2.

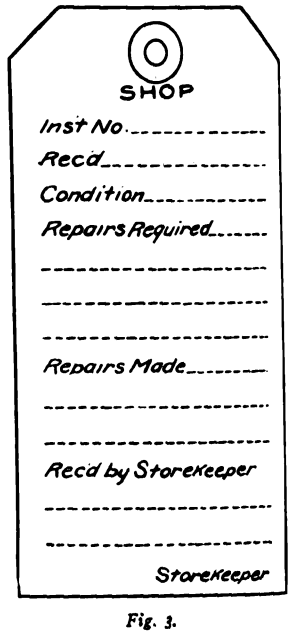

Fig. 3.

apparatus remains too long in the shop reports the same to the proper person. This keeps the shop from getting clogged with a lot of useless stuff as is too frequently the case. The shop man reports all instruments destroyed or too badly damaged for rehabilitation, and the clerk enters such on his "dead list" or transfers the card to a dead box, marking it with the information he has regarding the damage.

It is a simple matter for this clerk to keep an accurate daily balance of instruments showing on a special sheet the exact number of instruments in use in the shop or storeroom, and lost or destroyed. The chances of error are small, and a test of this system covering a period of one year, during which three thousand telephones were installed, showed an exact and true balance at the end of the year as determined by actual count and the auditor's record which was kept from other sources of information for a special purpose.

A PROGRESSIVE OHIO COMPANY.

THE Gratiot and Brownsville Telephone Company, with an exchange at Gratiot, Ohio, was organized May 21, 1904. Since then over 100 telephones have been placed among the business men and farmers in and around Gratiot, Brownsville, Mt. Perry and Hopewell and new subscribers are added almost daily. The company expects to have 150 or 200 by January 1, 1905. The Independent Long Distance Telephone Company and the local company have organized a traffic agreement which will give the telephone users exceptional long distance facilities.

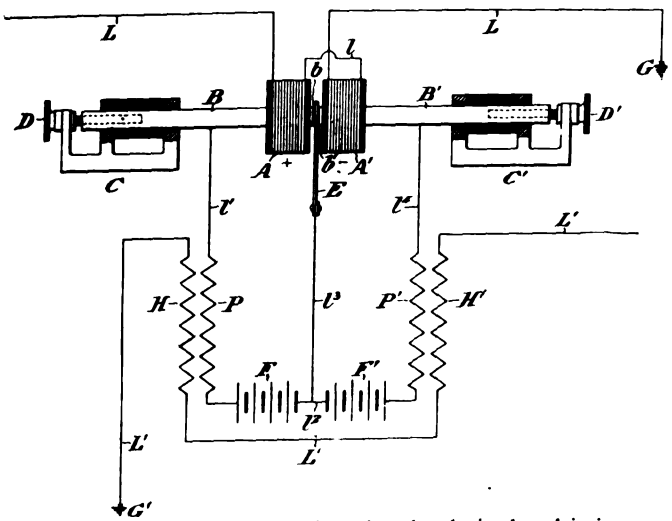
TELEPHONE PATENTS

TELEPHONE RELAY.

I. Kitsee, of Philadelphia, Pa., patents (No. 770,296) a telephone relay and assigns to the Keystone State Telephone & Telegraph Co., of Philadelphia, Pa. The object of this invention is to provide an improved telephone relay. The line wires traverse two coils *A* and *A'* which are placed upon the poles of two electromagnets. Between the poles of these magnets is placed the

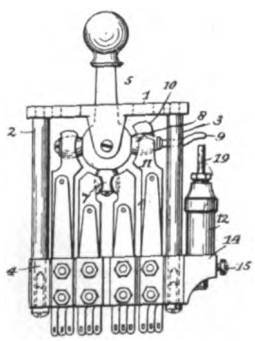


flexible armature *E*, which is of steel and polarized and is in contact with the two microphonic buttons *B* and *B'* that cap the poles of the magnets. Voice impulses traversing the coils *A* and *A'* will attract and repel the polarized flexible armature *E*, and consequently vary the pressure which it exerts upon the buttons *B* and *B'*; these through microphonic action will repeat, and the inventor claims, intensify, the original voice impulses.

AUTOMATIC RINGING KEY.

L. M. Ericsson, of Stockholm, Sweden, patents (No. 770,424)) an automatic ringing key and assigns to Aktiebolaget L. M. Ericsson & Co., of Stockholm, Sweden. The object of this invention is to provide an automatic ringing key which is con-

Fig. 1.



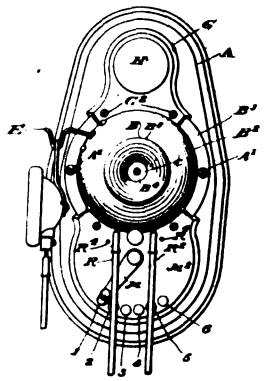
trolled mechanically and not electrically. The mechanism is shown in Fig. 1, from which it appears that the key contains the ordinary ringing and listening springs which are operated by means of a lever *5*. This lever carries a projecting arm *9* which impinges upon a rod *19* attached to the piston of a dash pot. When the key is thrown to the right the arm *9* forces the rod *19* downward, compressing the spiral spring contained within case *12*. This case forms a cylinder filled with some viscus fluid which slowly passes through the piston by means of holes drilled therein, consequently the ringing key will remain set and the ringing current applied to the line as long as the rod *19* is depressed, but as soon as the tension of the spring overcomes the viscosity of the fluid, the key is released and the ringing stopped.

TELEPHONE AND TELEGRAPH SYSTEM.

F. E. Denzer and W. W. Black, of Everett, Wash., patent (No. 769,306) improved telephone signal. This invention relates to improvements in telephone and telegraph systems whereby any number of instruments may be attached to one line or wire in such a manner that any station may signal any other one selectively, and then when the communication has been established a busy signal notifies all other stations that the line is engaged. This invention is based upon the familiarly step by step system, whereby the different stations are provided with electromagnets which operate toothed wheels that by means of the electromagnets may be set in such a position as to allow any station to signal selectively any other one, and which when properly actuated upon the line to all other stations.

TELEPHONE.

W. B. Churcher, of Cincinnati, Ohio, patents (No. 769,304) and assigns one-half to Albert F. Maish, of Cincinnati, Ohio, an improved substation set. The object of this invention is to provide a particularly compact substation set. The arrangement of the parts is shown in the illustration, from which it will be seen



that the hook switch is set inside of a cup shaped metal shield which contains the transmitter. Above this the ringer is placed, while underneath the transmitter a switch is mounted so that the instrument may be used as an intercommunicating set.

IMPROVED MOUTHPIECE FOR TELEPHONE TRANSMITTERS.

I. S. Ashe, of Philadelphia, Pa., patents (No. 772,310) an improved mouthpiece for telephone transmitters. The object of this invention is to provide a mouthpiece for a transmitter so arranged that two persons can use the transmitter simultaneously, and also to provide a valve which shall prevent the entrance of dust into the mechanism of the instrument. The inventor attains his object by providing a double funnel which may be attached to any ordinary transmitter by unscrewing the usual mouthpiece. Each funnel is provided with a sliding diaphragm which operates as a valve to exclude dust.

AUTOMATIC TELEPHONE EXCHANGE SYSTEM.

A. M. Bullard, of New York, N. Y., and L. A. Falk, of Boston, Mass., patent (Nos. 772,023 and 772,024) an improved automatic telephone system, particularly those which are used for intercommunicating circuits in small communities or in factories or large offices. The patents are so complicated that it is impractical to describe them in an abstract, and so voluminous that our space will not permit of their reproduction. We recommend those interested in systems of this description to procure copies of the original patents.

The Editor's Page.

AN IMPORTANT DECISION ON CONTRACTS.

THE litigation between the Western Union Telegraph Company and the Pennsylvania Railroad Company which has been in progress for some time, has many points that must be of exceptional interest to telephone operators. The contract between the Western Union and the Pennsylvania provided for the construction, maintenance and operation of a telegraph line along the right of way of the railroad company, which was to furnish and place the poles and cross arms, while the telegraph company was to furnish the wire, insulation, and instruments, and operate the line, sending messages relating to the railroad business free, and having itself the commercial business. The railroad company was given the right to string a wire for its own business and the telegraph company an additional wire, and provision was also made for the repair and renewal of the line. The line was built and operated under the agreement for many years, during which time it became an important part of the general system of the telegraph company, which by mutual agreement largely increased the number of its wires, and parol modifications were also made as to the expense of repairs and reconstruction.

The railroad company finally declared that it wished to terminate the contract and threatened to remove the lines of the telegraph company. The latter sought an injunction to restrain the threatened action. The circuit court of the United States for the Western District of Pennsylvania dismissed the suit upon demurrer to the bill of complaint. This action was reversed by the United States Court of Appeals. The court held that as the contract was not revocable at the will of either party, or otherwise limited as to its duration by its express terms, or by the inherent nature of the contract itself with reference to the subject matter or the parties, it was presumably intended to be permanent and perpetual. The relations created between the parties to the contract were not merely personal, as in cases of partnership, master and servant and the like, but rights of property and the user thereof, in the nature of an easement, were conferred on the telegraph company and no right in the railroad company could be inferred to revoke or determine the same at will.

The contract contained one provision that was valid at the time it was made, but had since been declared by statute to be invalid. This was a provision that the railroad company should not permit any other telegraph company or individual to build or operate a line of telegraph along its road. The existence of this invalid provision was held not to affect the validity of the other provisions for which it did not constitute the main consideration. It was also held that a court of equity was not precluded from decreeing the specific performance of a contract because it was continuous in its operation.

A REMARKABLE SHOWING ON THE PACIFIC COAST.

THE results achieved by the Home Telephone Company in Los Angeles, Cal., offer a text for the promoters of Independent competition that should be most convincing to capitalists, municipal officers and the general public. It is doubtful if anywhere in the world a similar progress can be shown. Even the remarkable telephone development that has characterized Sweden, owing to the freedom from Bell influences that that company has enjoyed, is overshadowed by the Los Angeles company.

AN INDEPENDENT OBJECT LESSON.

A conservative estimate of the population in that city to-day shows 155,000 people. The Home Company reports the installation of 20,000 telephones, or practically one telephone for each group of eight men, women and children.

A still more remarkable phase of this company's system is the extent of its private branch exchange business. There are nearly 200 private branch exchanges, some having 300 telephones.

Evidently the business people of Los Angeles appreciate efficient telephone service, and it is also apparent that the Home Company knows how to secure this business.

The system of toll and long-distance lines which radiate from this remarkable city of the Pacific Coast is developed to a point far beyond the expectations of its projectors. North, South, East and West there is hardly a hamlet that has not ample long-distance facilities. At the present time long-distance lines are being projected which will eventually cover the whole of California with a network of lines that will tap every village, and we might almost say, without overstepping the bounds of possibility, every house in this most wonderful and progressive country.

A careful investigation of this development would furnish an education without an equal to those whose interest in Independent telephony is commencing.

It is a fine object lesson in forecasting the future of the Bell situation throughout the country when the Independents settle down to business, for the Los Angeles company has practically driven its Bell rival out of the field as an efficient factor in the telephone situation in Southern California.

NECESSITY OF SIMPLICITY IN PATENT DESIGN.

THE tremendous activity in the telephone industry is particularly noticeable in the number of patents which are being or have been applied for. This shows that the Independent movement has given an unprecedented opportunity for the exploitation of ideas, some, if not all, of which have a very large element of originality and merit.

On an average there are six patents relating to telephony issued weekly. These cover almost every conceivable idea that can be described on paper from most fearfully and wonderfully contrived apparatus for party-line operation to the somewhat novel but simple idea of furnishing two mouthpieces for a transmitter. In many instances a careful consideration of the claims of a patent reveal a very meritorious idea, but unfortunately that seems to be the end of it.

The only apparent reason for this is the haste with which a device is prepared for the patent office. It is generally conceded that the first conception of an idea is generally too complicated, especially if the invention relates to a combination of functions. These complications can only be simplified or eliminated by careful study and much thought. Unfortunately the average inventor rarely thinks of this and rushes blindly ahead with a vague idea, which if more time and forethought had been used might have become a valuable asset instead of only a waste of money in patent fees.

Too much emphasis cannot be placed upon the necessity of care and attention to the simplification of details in the design of a circuit or piece of apparatus. That this is a most important consideration is proven by a review of telephone development.

The Telephone in the Courts

Conducted by A. H. McMillan.

Readers are invited to submit questions on any point of Telephone Law. They will be answered and explained on this page.

CONNECTION WITH INTERIOR SYSTEM.

We should be pleased to make inquiry if a recent decision has been made relative to a firm owning outside connections, obliging them to give service to interior systems over their lines. Any information you can give regarding this will be thoroughly appreciated. A. D. L.

THE latest decision on this subject is Gardner v. Providence Telephone Company (R. I.) 49 A. 1004. It was there held that a company might not forbid the use by a subscriber of a private set of extension instruments and refuse him the use of its line where the company was unprepared or neglected to furnish approved appliances of that kind or demanded exorbitant rates, the use of such set by the subscriber causing no detriment to the company either in its demand upon service or in safety.

PENALTY STATUTE AND DISCRIMINATION.

Does a statute prohibiting discrimination by telephone companies require one company to connect with another company? W. M. K.

AS a rule a telephone company is obligated to furnish its instruments and facilities to all persons willing to accede to its terms, and to obey its reasonable rules and regulations. So a penalty statute prohibiting discrimination by telephone companies applies to discrimination between applicants as well as patrons, and such companes cannot refuse to connect two subscribers. But such a statute does not require that one telephone company should connect its system with another company so that the latter may utilize the combined system as its own, and so be obligated only to the payment, for its own messages transmitted thereby, of the nominal sum required of subscribers. But refusal of a telephone company to connect the instrument of a subscriber with that of another patron renders it liable under such a statute as to discrimination and partiality, as the duty imposed does not cease upon furnishing the instrument and connecting it with the exchange. Re Baldwinsville Teleph. Co., 24 Misc. (N. Y.) 221, 53 N. Y. Supp. 574. Joyce on Electric Law; Section 840.

LIABILITY FOR DAMAGE FROM LIGHTNING.

A PLAINTIFF sued an electric lighting company for damages because of the destruction of his house by fire, alleging that the wires that entered the building were not properly insulated. The junction with the house wiring was on the inside of the upper story. This part of the house was not completely floored. The wires entered the house through auger holes in the window casement. There were no porcelain tubes or clay bushings where the wires penetrated the casement. In the unfloored space between the casement and the point at which it passed under the floor, there were 2 or 3 feet of slack in the wire. Such wire as was visible was in a damaged condition, frayed, and the insulation was loose upon it. It was not held tight at the point of entrance. It was an old wire and had been in that condition from the time it was put there. There were porcelain insulators on the eaves of the house from which the wires ran into the window and similar insulators along the garret joists, on the inside. There was no fuse box at the window.

At the time of the fire there was no electric light burning in the house, it having "popped off" a short time before. A severe electrical storm was raging during which there was a peculiarly bright flash of lightning, followed by a heavy clap of thunder. The fire was observed coming from the roof of the house a short time thereafter. Plaintiff's theory was that the rain blown in at the auger holes of the window casement had wetted the woodwork and wires, creating a "short circuit" and setting fire to the woodwork. Plaintiff recovered and defendant appealed.

The court held the essential error in the case to be the submission to the jury of any question as to the defendant's liability for the failure to insulate these wires against electricity, having its origin in the clouds or atmosphere. Where a person proceeding in a lawful business exercises reasonable care, the law does not make him an insurer against the negligence of his actions, which reasonable care and foresight could not have prevented.

The law justly ascribes such consequences to inevitable misfortune or to the "act of God," and leaves the harm resulting from them to be borne by him upon whom it falls. Defendant's duty did not extend so far as to require the insulation of those wires in a manner to protect against injurious consequences of a lightning stroke, for the evidence showed that it was not practicable to insulate them against lightning.

If the wires were sufficiently installed and insulated for the purpose of carrying lighting into the plaintiff's house the court said it felt that in submitting to the consideration of the jury any question of negligence based upon the defendant's failure to insulate against a foreign current of electricity the trial court was inviting them into the realm of speculation in which conjecture, and not evidence, must guide them. The judgment obtained by the plaintiff was reversed.

Phoenix Light and Fuel Co. vs. Bennett (Ariz.) 63 L. R. A. 219.

TELEPHONE COMPANIES AND RAILROAD COMMISSION.

THE Louisiana Railroad Commission at its August meeting gave considerable attention to telephone companies with the following result:

A hearing having been accorded the Cumberland Telephone and Telegraph Company of Louisiana upon the question as to the length of time subscribers shall be compelled to contract for telephones, and after due investigation, the commission being of the opinion that the present rule allowing the said company to require telephones to be taken for a period of one year, or when taken for a less time, to charge the subscribers with the cost of installation, is unjust and unreasonable, it was ordered that order No. 315, entered Nov. 4, 1903, and published in the official journal of the commission at Baton Rouge, La., Nov. 6, 1903, be and is hereby canceled.

It was further ordered that telephone companies shall hereafter be allowed to make contracts with new subscribers desiring telephone service, to keep the telephones for a period of six months from date of beginning of service, at rates authorized by the commission for the class of service desired. If any party desires telephone service for a less period of time than six months, it shall be furnished at the rates authorized by the commission for the class of service desired, provided, the party desiring service pays the actual cost of installation.

A complaint was filed with the commission on July 25, 1904, signed by several residents of the parish of West Feliciana, alleging that they had enjoyed telephone service as subscribers to the Cumberland Telephone and Telegraph Company at rates made by the said company; but that on or about the first of February, 1904, the rates they were paying were raised. It is hereby ordered that the Cumberland Telephone and Telegraph Company shall not demand, receive, charge, or collect from any of the signers of the petition in this case, or from any others not signers thereof, similarly situated, who have enjoyed telephone service at certain rates established.

IN THE OPERATING FIELD.

KANSAS CITY COMPANY BUYS LONG-DISTANCE LINES.

REPRESENTATIVES of the Kansas City Home Telephone Company and the Western Independent Telephone Company held a meeting recently to finish the negotiations whereby the long-distance lines of the last named company are to be taken over by the Home Company. Those in the meeting were: E. L. Barber, Wauseon, O.; James S. Brailey, Jr., Toledo, O.; Lee Benoist, St. Louis; Arnold Kalman, St. Paul, Minn.; J. J. Heim, O. C. Snider and Hugh C. Ward, Kansas City.

Mr. Ward, as counsel for the Kansas City Home Telephone Company, said:

"We are closing up a deal in which the Home Company obtains the Independent lines. We are also considering to-day the idea of building and extending our lines from Ottawa, Kas., throughout the gas and oil fields of Kansas and the Indian territory. This is practically decided upon. The telephone business is prosperous. Our company has gained 600 subscribers a month since May 1st last and the long distance calls are increasing in a like ratio."

STROMBERG-CARLSON COMPANY MOVES FACTORY.

THE Stromberg-Carlson Telephone Manufacturing Company, which has heretofore had its headquarters in Chicago, is at the present time engaged in transferring its plant to Rochester, N. Y. This company has erected a magnificent factory and when it is in working order it will be able to turn out twice the amount of finished products as was possible previous to this time. All the latest and most approved ideas in factory design have been employed, and the latest types of labor-saving machinery installed. The entire management of the company will be located in Rochester, N. Y., after November 1, including the sales department, which will be in charge of Mr. Charles W. Steger, formerly of the Chicago office. The Chicago sales office, at 70 West Jackson boulevard, will be under the direct supervision of Mr. J. P. Cracraft, and it is the intention of the company to keep a show room, in which will be displayed every kind of apparatus manufactured by the company.

TELEPHONES IN CHURCH.

OFFICIALS of the Congregational church of Sherburne, N. Y., have sanctioned the installation in the pews of a telephone system by which they hope to have the people of the congregation who are hard of hearing enjoy the sermons as well as the rest.

Fred I. Shepard, general manager of the local telephone company, is perfecting the system, connecting each of the pews with a line running directly to the pulpit. A specially constructed transmitter will be placed near the preacher's head so that his remarks will be received and transmitted by it.

LONG-DISTANCE DEVELOPMENT IN SOUTHERN CALIFORNIA.

DEVELOPMENT of long-distance lines on the Pacific Coast is being rapidly pushed forward. New toll lines are being added constantly where the former lines were thought ample at time of construction. All the important towns in Southern California have Independent long-distance connections, and the system is being extended to reach every point. The United States Long Distance Telephone and Telegraph Company is constructing new exchanges in the following cities: Ocean Park, Santa Monica, Westminster, Smeltzer, Huntington Beach, Glendale, Burbank, Tropico, Oxnard, Ventura, Riverside, Colton, Carpenteria, San Pedro, San Diego, Redondo and five branches in Los Angeles.

Besides these exchanges ten others are increasing their capacity to meet the increased demand for long-distance service. Additional toll lines are being built to Compton, Santa Ana, Pasadena, Redlands, San Bernardino, Monrovia and way points, and new toll lines are being constructed to Redlands and way points, and to Smeltzer, Westminster, Huntington Beach, Riverside, Newport Beach and intermediate points from Los Angeles.

JOHN M. HUMISTON JOINS FIRM OF McMEEN & MILLER.

THE firm of McMeen & Miller has recently acquired the services of John M. Humiston, who is an expert in problems of electrolysis. Mr. Humiston has been connected with the engineering department of the Chicago Telephone Company for the past eight years, being engaged upon engineering and construction work. Educated at Lake Forest University, Lake Forest, Ill., and the Armour Institute, he completed his college training in 1896, and entered the employ of the Chicago Telephone Company in that year, and through quick application at once climbed to an important position in that company's service.

In connection with the protection of pipes against damage by electrolysis Mr. Humiston has been for some time consulting electrical engineer to the Shreeveport (La.) Gas and Electric Company, the Ottumwa (Ia.) Gas Light, Heat and Power Company and to six or seven other companies in Indiana, Illinois and Wisconsin, having to meet similar problems.

Mr. Humiston is an associate member of the American Institute of Electrical Engineers. His Chicago address will be that of the firm of McMeen & Miller, 1442-1443 Monadnock Block, and he will be in charge of the firm's branch office, to be maintained for some months in the future at Quincy, Ill., during the progress of the engineering construction of the new Independent telephone system of that city.

RECEIVER FOR NORTH DAKOTA COMPANY.

C. E. BURGESS, a stockholder of the North Dakota Telephone Company at Grand Forks, N. D., seeks to have the affairs of the corporation wound up, and a receiver appointed on the ground that the telephone line has been converted into a telegraph line almost entirely to the exclusion of the telephone business. Edwards, Wood & Company are said to own the majority of stock by recent purchases.

S. H. COUCH CO. INCORPORATES.

THE well-known firm of S. H. Couch Co. has recently been incorporated, and will be known hereafter as the S. H. Couch Co., Inc. The prominent telephone specialist of Boston, S. H. Couch, is president and William Couch is secretary. The same high standard of excellence which this firm has adhered to in the past will continue in the future.

THE BELL GIVES FREE SERVICE?

THE telephone users of Sodus, N. Y., are greatly incensed over a recent manouver of the Bell in this territory. For a number of years the merchants of this town had made overtures to the company to secure an exchange with service at from $15 to $18 per year without success. When the Wayne

Digitized by Google

Monroe Company began to solicit for contracts it immediately sent an agent with an offer to install an exchange and give three months' service free. The solicitors secured about sixty contracts, with the provision of free service, which was to extend from July 1 to October 1.

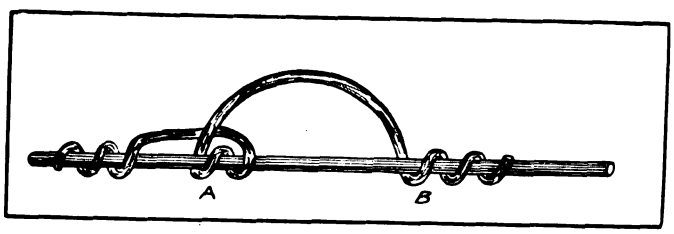
Recently all the subscribers to the system received bills for the three months which were supposedly free, and this has caused a great deal of indignation. The Wayne Monroe Company has secured 150 subscribers, and is in a position to give long-distance service over the lines of the Inter-Ocean Company and the Rochester Home Telephone Company .

ROME, N. Y., A PROGRESSIVE TELEPHONE TOWN.

ABOUT the first of next month a new telephone directory will be issued by the Rome, N. Y., Home Telephone Company. It will be a combination directory and will contain the names of Rome, Utica and Herkimer subscribers; also the subscribers from other exchanges in the Mohawk valley. Rome is one of the best telephoned cities in the United States, there being 1,040 telephones. The exchange was opened October 1, 1900, provision at that time being made for only 500 telephones. The company is extending the cable system to make provision for the many new subscribers who are now on the waiting list.

NEW METHOD OF TYING LINE WIRES.

MR. CHARLES CLAYDON, Tabor, Texas, sends us the following wrinkle in open wire line construction which may be of use, so we illustrate the same for the benefit of our readers. Mr. Claydon's device consists in an improved method of tying the line wire to the insulator, which is shown



in the accompanying illustration. The particular feature consists in turning the tie wire back over the loop formed around the insulator after three turns have been made around the wire and then securing it with three additional turns outside of the first lashing.

THE NATIONAL TELEPHONE COMPANY ADMITTED TO INDIANA.

THE National Telephone and Telegraph Company, of West Virginia, has been admitted to Indiana, and the company has filed a certificate of incorporation and a declaration to invest $175,000 in the building, equipping and operating telephone exchanges, toll lines, etc. The company also proposes to lease or connect with other telephone plants owned or operated by other individuals or corporations. The company's principal office will be in Fort Wayne, and in charge of Wm. L. Moellering, who has been selected as State agent. The Indiana stockholders are Frank H. Cutshall, Wm. Paul, and George T. Cox, of Fort Wayne.

RECEIVER FOR UNITED ELECTRIC COMPANY.

THE Chicago Title & Trust Company has filed a bill in the Circuit Court asking for an injunction against the United Telegraph, Telephone & Electric Company, which stirred the council and the city of Chicago, a year ago by applying for a telephone franchise for the whole city and forcing a most favorable ordinance through the committee on gas, oil and electric light. The trust company asked for an injunction, an accounting, and the appointment of a receiver for the telephone company. It is set forth that the interest on the corporation's bonds has become overdue. The United Company has a long-term telephone grant in the town of Hyde Park, and has for years operated a small exchange in that section of the city. Eighteen months ago the corporation, which was then little known, was re-enforced by new capital and appeared on the council horizon as a competitor to the Chicago Telephone Company.

First, the concern got permission to run a ten-wire cable through the city's conduits from Hyde Park to the center of the city and connect with ten buildings in the downtown district. Next, the corporation came in with a petition for a franchise for the whole city. The ordinance was carried through the committee on gas, oil and electric light after several stormy sessions. A measured service schedule, which would have permitted of higher rates than the Chicago Telephone Company, was a part of the ordinance. So strong a protest was voiced against the action of the committee in recommending the ordinance that its backers gave up the fight, and made no attempt to get the ordinance through the council.

The bonds on which the interest is now alleged to be in default were floated at about the time the application for a franchise was made to the council. The capitalization of the company is $500,000. The outstanding bonds total $174,000. The bonds were secured by a trust deed now held by the Chicago Title & Trust Company. The Trust Company petitions for foreclosure proceedings if the telephone corporation is found unable to meet the obligation.

MR. SAPP JOINS THE CONTROLLER COMPANY.

MR. FRANK F. SAPP has just assumed entire charge of the Promotion and Publicity Department of the Controller Company of America, with general offices at 1061 Monadnock Block, Chicago, Ill. Having for a number of years been general sales manager in charge of the sales and advertising departments of the North Electric Company, of Cleveland, Mr. Sapp is known far and wide in the telephone industry. The change came about through his desire to be more actively identified with the measured-service movement. He has carefully fitted himself for taking hold of this work, and his many friends believe that he will be just as successful in his new capacity as he was with the North Electric Company. He leaves the latter concern with their best wishes. While with the North Electric Company Mr. Sapp acquired the reputation of being one of the most successful sales managers and also one of the most original advertising managers connected with the telephone manufacturing and supply business. He thoroughly organized the selling branch of that concern and it is known that his energy and diplomacy increased the company's business largely. It was, however, in the preparation of pulling advertising copy and attractive catalogues and literature that Mr. Sapp particularly excelled. His copy attracted wide attention on account of its originality and strength, and the North catalogues produced under his direction are considered models of refined and tasteful advertising literature.

BRITISH SUB-MARINE SIGNALING.

BRITISH naval authorities are awaiting with interest the results of a series of experiments that are being conducted with a view to establishing a system of sub-marine signaling. The theory involved is based upon the conductivity of water of waves of vibration. Granted this being correct, if the hull of a submarine is sharply tapped the noise is communicated through the water to a special type of receiver, which makes the noises audible. The present experiments are to determine the distances through which these signals can be transmitted. The difficulty so far encountered is best expressed in the words of one of the officers in charge of the work:

"You must be entirely submerged so as to lose no proportion of the sounds through diffusion into the atmosphere," he said. "The conductivity of water is remarkable. One of the best examples lies in the exaggeration of concussion below the surface.

"It is well recognized that had the unfortunate Al been on the surface, in buoyant trim, when the Castle liner struck her at no greater speed than nine knots, her occupants would have been little the worse for the shock. As it is, there can be no doubt from the postures in which the crew were found that they were stunned to death."

It is therefore evident that a limitation is placed upon the use of severe concussions for long distance signaling.

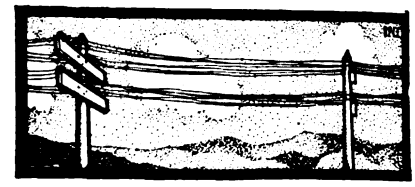
QUERIES

Questions on any subject relating to telephony will be answered on this page.



OHMMETER QUERIES.—(444.)

Please answer the following questions through your query column:

1—Does it make a difference what size wire is used for the ratio arm of the ohmmeter you described previously in your magazine?

2—You make the statement that No. 18 resistance wire averages about an ohm per foot. What kind is it, and where can it be obtained? Persons of authority claim six feet is needed per ohm.

3—In your article on the ohmmeter you divide your scale into 500. I have 900 to mine and ten feet long. How high can you go on the scale and get correct results? Can you go to the highest division? If so, how will I determine resistance with my scale? For instance, your formula is subtract balance point from total divisions, and multiply by coil in circuit. If galvanometer balances at highest division on your scale with one ohm coil it would be 500 ohms, and with mine 960. J. T.

1—The size of the wire used for the resistance wire in the ohmmeter is not a matter of great importance. If the wire is too small it may break and require replacement, whereas if it is too large, the resistance per unit of length is likely to be so low that it is

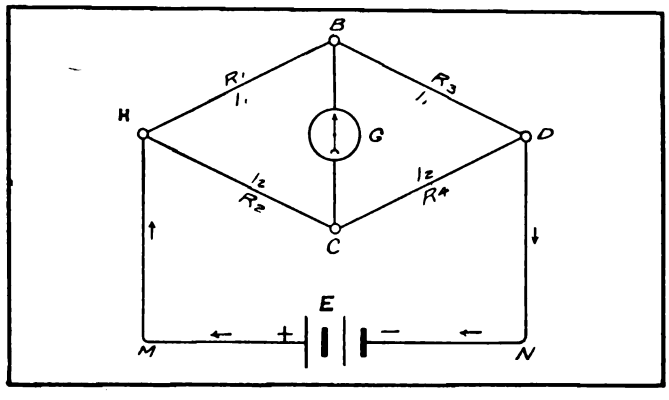


Fig. 444a.

necessary to move the contact point over a long stretch of wire in order to make any sensible difference in the ratio of the segments into which the wire is divided by the contact.

2—A great many different kinds of resistance wire are made, and it is possible for you to obtain No. 18 wire that shall average more or less than an ohm per foot, as you desire. The kind of wire which was suggested in our article is called Manganin wire, and can be obtained from Foote, Pierson & Co., 82-84 Fulton street, New York City.

3—Your third question can be best answered by a consideration of the theory of the Wheatstone bridge, which is as follows: Suppose in Fig. 444a that the points *H* and *D* are joined by six conductors, namely, the conductors *H B* and *B D*, the conductors *H C* and *C D* and the conductors *H M E* and *E N D*. Suppose the battery *E* to be placed in the conductor *H M E N D*, the current will then tend to flow in the direction *E M H*, and at the point *H* it will divide into two parts, one portion flowing through *H B D* and the other through *H C D*.

By using large wire no serious error will be introduced by assuming that the conductor *H M E N D* has no resistance and that the full electromotive force of the battery *E* is applied to the points *H* and *D*. Then between the points *H* and *D* there will be the same fall of the potential *E* along the two paths *H B D* and *H C D*, and, therefore, for *every point* on the path *H B D* there can be found some point on the path *H C D* which is at exactly the same potential. Suppose *B* and *C* be in two such points so that the fall of potential from *H* to *B* is the same as the fall of potential from *H* to *C*, and that the drop from *B* to *D* is the same as the drop from *C* to *D*.

In the first place consider what happens when the points *D* and *C* are not connected. A certain current *I*, will flow between *H* and *D*, and evidently this current will be the same in the portion *H B* as it is in the portion *B D*. Some other current will flow through the path *H C* and *C D* and may be designated as I_2, and it is evident that the current I_2 in *H C* will be the same as the current in *C D*.

Now if the points *B* and *C* be at the same potential and if they be joined by a conductor *B C*, no current will flow through this conductor because there is no difference of potential between *B* and *C*, and consequently joining these points by a conductor will not change the current relations in either of the conductors *H B*, *B D*, *H C* and *C D*. The fall of potential in the circuit is equal to the product of the current and the resistance. Hence, if the resistance *H B* is R_1 and the current I_1, the drop is $R_1 I_1$. Similarly in *H C* if the resistance be R_2 and the current I_2 the drop is $R_2 I_2$. It has been assumed that the drop between *H B* is the same as the drop between *H C*, hence $R_1 I_1 = R_2 I_2$.

Also for the conductors *B D* and *C D* a similar equation may be written; that is to say,

$$R_3 I_1 = R_4 I_2$$

Divide one of these equations by the other, obtaining:

$$\frac{R_1 I_1}{R_3 I_1} = \frac{R_2 I_2}{R_4 I_2}$$

On each side of the equations cancel out the *I*'s, leaving:

$$\frac{R_1}{R_3} = \frac{R_2}{R_4}$$

This may be written in the form of a proportion:

$$R_1 : R_2 :: R_3 : R_4$$

Hence $R_2 = \frac{R_3}{R_1} R_4$

From this last equation it is evident that if there is an unknown resistance R_2 in one arm of the bridge, a known resistance R_4 in the adjacent arm, while the ratio of the other two arms is known, the value of the unknown resistance can be obtained as the product of the ratio of two of the arms multiplied by the remaining arm.

Fig. 444b is the diagram of the circuit of the ohmmeter in which R_2 represents the arm into which the resistance to be measured

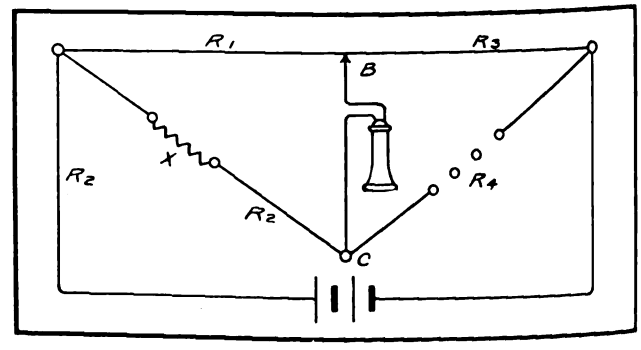

Fig. 444b.

is introduced. R_4 is the arm containing the adjustable resistance coils, while R_1 and R_3 are respectively the segments into which the contact point *B*, connected to the telephone, divides the resistance wire. Inasmuch as the wire is in uniform size and uniform composition, it has uniform resistance per unit of length, and consequently the resistance will be proportionate to the length of each segment, and therefore the ratio of the resistance will be the same as the ratio of the lengths, and so it is unnecessary to

Digitized by Google

know the actual resistance, and therefore wire of any resistance, provided it is uniform, will serve the purpose.

The accuracy with which measurements can be made with the ohmmeter depends upon three things: First, the accuracy with which the coils used in the arm R_4 are adjusted. If the resistance of these coils is known within 1, 2 or 4%, the measurement of the unknown resistance will be within the same limits, 1, 2 or 4%.

Second, the accuracy depends upon finding with contact B the point along the wire which is at the same potential as the point C, If a telephone is used as a detector, accuracy will depend upon the sensitiveness of the telephone, the acuteness of hearing of the observer, and the care with which the contact point B is adjusted.

Third, accuracy depends upon the exactness with which the two segments R_1 R_3 are measured. For example, if the wire were one inch long, it might be possible to adjust the contact point within a 100th of an inch, and consequently the accuracy would be limited to 100th of an inch, or 1% of the length of the wire; but if the wire were 100 feet long, the contact point could be adjusted with exactly the same accuracy, namely, to 100th of an inch, and therefore the accuracy would be within, approximately, about 100th of 1%. Therefore, in a general way, the longer the wire the greater is the probable accuracy to be expected.

USE OF REPEATING COILS.—(445.)

What are the principle uses of repeating coils? N. A.

Repeating coils, as their name indicates, are used for repeating from one circuit to another. Their principal uses are to join subscribers' instruments to long toll lines, and to join magneto systems to common battery.

THE NEED OF A TRAFFIC ASSOCIATION

By H. E. Bradley.

THE time will soon come if, indeed, it has not already arrived, when the proper handling and accounting for long-distance messages will become a vital question to all Independent companies.

In speaking of long-distance, I refer only to messages of one hundred miles and upwards, and messages which pass over the lines of more than two separate companies.

There are many Independent companies who are at the present time operating lines more than one hundred miles in length, and giving good service. There are many cases where separate companies are interchanging business. But trouble generally comes when messages are originated in the territory of one company, pass over the lines of one or more intervening companies, and terminate in the territory of a third or fourth company.

These troubles may arise from any one of a number of different causes, but up to the present time there is too much of a tendency to lay it to the other fellow, and until the time comes when the companies are more willing to get together, toll business must suffer.

As soon as the toll lines have reached out until a connection has been established with an adjoining company, the toll service has reached the dignity of long distance.

Messages originating in the territory of one company, and terminating in the territory of the connecting company are easily cared for with little trouble, as such business is covered by a single agreement, but one division of the toll is necessary, and settlements are easily arranged.

Now come the messages which are originated by one company, pass over the lines of two or more intervening companies, and finally terminate in the territory of a fourth or fifth company.

With these connections also come the troubles of settlements. If there are five separate companies, there are five separate settlements, and five separate bunches of trouble, for there are sure to be differences in each report.

How is this business to be cared for in the shortest time, and with the least trouble? The usual reply is, let each company settle with its connecting company. This sounds well, and looks easy, but those who have had experience know it to be troublesome and expensive, and slow. The company who collects the tolls will get its share, the through company will get all it can, and the company who terminates the message gets whatever is left. If it is the proper amount, well and good; if it is not, it's difficult to prove who has taken an undue proportion. Then begin the troubles of readjustment, which often cover two to three months, during which new settlements are coming in, and the usual outcome is a general decision by all companies to "keep what you've got and let it go at that."

How are these settlements to be made with fairness to all, in the shortest time, and at least expense?

Many of the Independent companies have found the answer in the traffic association, an organization which has an equal interest in all its members, large or small, and yet is partial to none.

The object is to promote interchange of business, to publish necessary rates and routing directions, and to facilitate settlements.

Instead of making five separate reports each company makes but one, and that to the association. The association checks and settles all differences and divides equally, fairly and impartially all tolls. It acts as a court of arbitration where all disputes and misunderstandings can be adjusted, and extends to all its members the same benefits.

One of the greatest to be derived is the publishing of rates and routings in book form, showing the proper toll charges, and the different routes over which the messages may be carried, together with a complete list of checking and other line points.

This work if done by the individual company would become a large item of expense, but by centralizing the work and the association, and combining all under one cover, a most valuable book is obtained at a minimum of cost.

Independent long-distance service is still in its infancy, but it is growing, and growing rapidly, and if the Independent companies and associations will only work together, for the common good of all, forgetting past disputes and petty disagreements, there is no reason why the success so much desired should not crown our efforts.

Editor's Note.—Extract from an address made before Penna. State Ind. Tel. Assn. Convention.

A NEW APPLICATION OF TELEPHONY.

A COMPANY has been promoted in Spokane, Wash., to furnish musical programmes to subscribers by means of the telephone. This company, known as the Pacific Telharmonic Company, with headquarters at Seattle, is reported to have secured the exclusive rights west of the Rocky Mountains, of a device invented by Thaddeus Cahill, of Holyoke, Mass. A special transmitting devise has been perfected which enables a musical number to be simultaneously distributed over any number of circuits.

By means of this invention, it is claimed, a single central station at San Francisco could, if thought desirable, distribute music to nearly 600,000 people; one at Los Angeles, to about 300,000; one at Denver, to nearly 500,000; one at Portland, to 200,000; one at Seattle, to 250,000; one at Spokane, to 100,000, and so on.

The officers of the company are: C. J. Smith, president; John H. McGraw, vice-president; J. W. Clise, treasurer; F. A. Wing, secretary; T. O. Abbott, counsel and general manager. A. S. Kerry and Robert T. Reid, together with the foregoing persons, constitute the board of trustees.

THE WEEK'S MESSAGES

FINANCIAL.

RUSHVILLE, IND.—The annual meeting of the stockholders of the Rushville Co-operative Telephone Company was held Friday night. The annual report of the secretary showed the receipts for the year to be $15,404.91. The disbursements were $14,664.78, leaving a balance of $440.13. H. E. Barrett, W. D. Root, Ben L. McFarlan and T. M. Green were elected directors.

ST. JOSEPH, MO.—The Clarksdale Telephone Co. has increased its capital stock from $2,500 to $5,000, and will put in additions to the plant.

WILLOUGHBY, OHIO.—The Kirtland Telephone Company has increased its capital stock from $2,500 to $5,000.

WYTHEVILLE, VA.—At the meeting of the Wythe Mutual Telephone Company it has amended its charter so as to issue $3,000 worth of preferred stock.

FRANCHISES.

HAZEN, ARK.—The city council has granted a franchise to the Hazen Electric Light & Telephone Company.

ESTHERVILLE, IOWA.—The Emmet County Telephone Company seeks a local franchise for a new exchange.

SHELDON, IOWA.—The Commercial Club has asked its president, G. A. Starrett, to ask the city council for a franchise for the construction of an Independent telephone system.

ONEIDA, N. Y.—The business men of this city are interested in having a local office of the Home Telephone Company installed here.

WEST HOPE, N. D.—The West Hope Telephone Company, represented by Messrs. Lilly, Rinkel, Neville and Frank Collins, appeared before the city council recently and applied for a franchise which was granted. This company has just been organized with about $2,500 worth of stock subscribed. It is contemplated to construct a local exchange and also do an extensive rural line business.

CYGNET, OHIO.—The town council has granted a franchise to the Oil Belt Telephone Company to install a new system of telephones in this city.

MIDDLETOWN, OHIO.—At the meeting of the city council the question of a franchise for the Home Telephone Company will be considered.

MUSKOGEE, IND. TER.—A new telephone system is asking for a franchise in this town.

LOWER MERION, PA.—The Keystone Telephone Company has applied for a franchise to operate a system in this village.

MORRISTOWN, TENN.—The Citizens' Telephone Company has applied to the city council for a franchise.

EVERETT, WASHINGTON.—An application for a franchise by the Skagit Farmers' Mutual Telephone Company was given its first reading before the city council recently. The new company wants a fifty-vear term. It has lines now operating in Skagit and Snohomish counties.

ELECTIONS.

BLANCHARD, IOWA.—The annual election of the stockholders of the Mutual Telephone Company was held recently and resulted in the election of the following directors: W. N. Dewhart, R. A. Salee, Edward Hensleigh and G. H. Whitmore. The directors will meet in the near future and elect another director, who will act as secretary and manager, and also a president and treasurer.

OSWEGO, N. Y.—The Oswego Telephone Company has elected the following officers: Dr. W. A. Moulton, president; Thomas Dean, vice-president; B. R. Whitcomb, secretary; W. H. Clark, treasurer. B. H. Sutfin and G. H. Horton, trustees.

NEW COMPANY NOTES.

SELMA, ALA.—The Maplesville & Selma Telephone Company has been organized at Selma with a capital stock of $4,000.

COLORADO CITY, COLO.—The El Paso Telephone Company has been incorporated with a capital stock of $500,000 by M. H. Spere, N. B. Hames, and C. D. Taylor. The company will extend its lines through the counties of El Paso, Teller, Fremont, Pueblo, Douglas and the city and county of Denver. The principal office will be in Colorado City.

WASHINGTON, D. C.—The National Telephone & Electric Company has been incorporated with a capital stock of $100,000 by B. F. Wasson, Ernest W. Porter and E. Richard Shipp.

TILDEN, IND.—The Tilden Mutual Telephone Company has been incorporated with a capital stock of $5,000 by M. F. McClung and James W. Ferree.

WEWOKA, IND. TER.—The Oklahoma Southern Telephone Company has been succeeded by the Jennings Telephone Company.

BARNUM, IOWA.—The Barnum Telephone Company has been incorporated with a capital stock of $10,000. It will install a local exchange.

ELDORA, IOWA.—The Eldora, Rough Woods and Point Pleasant Telephone Company has filed articles of incorporation with the secretary of the state. The capital stock is $10,000. E. H. Sheldon and others are the incorporators.

ELLSWORTH, KAN.—The Lyons Telephone Company has been incorporated in this city with a capital stock of $12,000.

ROSEHILL, KAN.—The Derby & Rosehill Telephone Co. has been incorporated, with a capital stock of $630, to construct a rural line between the two points.

THORNBURG, KAN.—The Thornburg Telephone Company has been incorporated with a capital stock of $1,000.

EASTBROOK, ME.—The Eastbrook Telephone Company has been incorporated with a capital stock of $2,000. The officers are: S. S. De Beck, of Franklin, Mass., president; R. B. Laurie, treasurer.

GENESEE, MICH.—The Shiawasse and Genesee Mutual Telephone Company has been incorporated with a capital stock of $10,000.

CERRO GORDO, MINN.—The Farmers' Mutual Telephone Company of Cerro Gordo has been organized with a capital stock of $20,000.

GOODTHUNDER, MINN.—The Farmers' Central Telephone Company has been organized with Charles Perlish, president, and G. A. Weidenheft, secretary.

MORRILL, MINN.—The Morrill Rural Telephone Company has been organized with a capital stock of $5,000.

NEWMARKET, MINN.—The Star Telephone Company has filed articles of incorporation with the secretary of state. Capital stock, $10,000.

STILLWATER, MINN.—The farmers of Stillwater and Grant Townships in this vicinity have organized the Twin Lake Rural Telephone Company.

WALDON, MINN.—A local telephone company has been organized and will build a line to Starbuck.

ZUMBRO FALLS, MINN.—The Zumbro Falls Telephone Company has been organized with a capital stock of $7,000 by Frank Robertson, Bert W. Dunsey and others.

KANSAS CITY, MO.—The Kansas Telephone & Construction Company has been incorporated with a capital stock of $75,000.

BENKELMAN, NEB.—The Dundy County Mutual Telephone Company has been incorporated with a capital stock of $3,000.

MACDOUGALL, N. Y.—The MacDougall Telephone Company has been incorporated with a capital of $5,000. The incorporators are A. Buldridge, R. C. Allen, and A. Buldrige, Jr., all of MacDougall.

PATCHIN, N. Y.—The Boston Valley Telephone Company of Patchin, N. Y., has been incorporated with a capital stock of $2,000 by L. G. R. Whiting and John W. Gasper, of Patchin, and F. A. Wurtz, of Boston, N. Y.

CAMDEN, N. J.—The Folding Cabinet Company has been incorporated to manufacture telephone cabinets. Capital, $10,000. The incorporators are: Charles A. Wolverton, of Bridgeport, and T. E. French, of Camden.

RUSHCREEK, OHIO.—The Rushcreek Telephone Company has been organized with a capital stock of $5,000. W. H. Petty is president; W. Klingler, secretary, and D. T. McCan, treasurer.

MEDFORD, OKLA.—The Medford Rural Telephone Company has been incorporated with a capital stock of $3,000.

UNION, OKLA.—The Union City Telephone Company has been incorporated with a capital stock of $5,000. The incorporators are: F. L. Wilkins, T. M. Kirby and L. S. Fuhring.

NEW CASTLE, PA.—An Independent telephone company is being organized by the Lawrence County farmers.

POTTSVILLE, PA.—The Mahanoy & Mahantonga Telephone Company has been incorporated with a capital stock of $20,000.

LETCHER, S. D.—A number of farmers residing west of here have organized the Storla Telephone Company, and are rapidly completing the work of extending lines through the rural communities. Four lines are being constructed. It is proposed to extend the lines northwest to the town of Lane, and southeast and southwest to the farming communities in those directions.

PARKER, S. D.—The Steininger Telephone Company has been incorporated with headquarters in this city and capital stock $50,000. J. A. Steininger of this city is president and general manager of the company, which is composed entirely of capitalists of this and nearby towns. Exchanges will be installed at Hurley, Marion, Monroe and Dolton. Rural lines will be installed at Hurley, Marion, Monroe and Dolton. Rural lines will be constructed throughout the county and contiguous territory.

TULLAHOMA, TENN.—Business men in this town at a meeting held recently took steps toward the organization of an Independent telephone company. The Cumberland Telephone Company has increased its rates by 100 per cent.

COMBINATIONS.

HARTWELL, GA.—The Hartwell Telephone Company has been purchased by F. P. Linder from L. M. Felton.

MAXWELL, IOWA.—F. G. Ainley has disposed of all his holdings in the Maxwell Telephone Company to James Prawl, the present manager of the company, Dr. L. P. Joor and H. M. Cole. A meeting of the new company was held and the following officers elected: P. Joor, president; H. M. Cole, secretary and manager, and James Prawl.

SYRACUSE, KAN.—The telephone system in this city has been sold by H. H. Jones to Clarence Daigh.

GRAND RAPIDS, MICH.—The Citizens' Telephone Company has secured a controlling interest in the Independent system at Marshall.

REDWING, MINN.—The Consolidated Telephone Company has obtained a controlling interest in the Redwing Telephone Company.

BUTTE, MONT.—Harry W. Turner and Max Hebgen of this city have purchased the Havre Telephone Exchange for $40,000 from Eric V. Haser of St. Paul.

MARLBORO, N. Y.—The Colonial Telephone Co. has secured control of the Local Telephone Company.

LE RAYSVILLE, PA.—Representatives of the East Herrick, Orwell,

Digitized by Google

Warren Centre, Neath and Jackson Valley Telephone Companies met in this town recently and merged their lines in a new company to be known as the People's Co-operative Telephone Company, of which following are the officers: D. Cowles, of Orwell, president; B. H. Phelps, of Stephens Corners, secretary; H. G. Newell, of Potterville, corresponding secretary; Rev. Hugh Jones, of Neath, treasurer. A movement is under way to extend the line south toward Stevensville and make connections with the Rush system.

WAYNESBORO, PA.—At a meeting of the subscribers of the local telephone company the project of leasing the United Company's Exchange was discussed.

MISCELLANEOUS.

HARTWELL, GA.—The Hartwell Telephone exchange has been purchased by F. P. Linder from L. M. Felton. Mr. Linder has purchased a large lot of supplies and will greatly improve the exchange.

DETROIT, MICH.—The Co-operative Telephone Co. has established connections with Toledo, where there is an Independent exchange of about 3,000 telephones. Points in Ohio and Indiana are reached through Toledo.

JACKSON, MICH.—J. B. Ware has made a proposition to the regents of the university to install citizens telephones at half the price paid the Bell.

LOWELL, MICH.—The Citizens' Telephone Company will increase both business and residence rates $3 per year. There are now 360 telephones in operation.

DALEVILLE, ILL.—The Daleville telephone system is being rapidly extended. There are now 150 telephones in operation and more lines will be built as soon as possible.

DANVILLE, ILL.—The Vermillion County Telephone Company has recently completed the installation of its new exchange in this city.

QUINCY, ILL.—Samuel G. McMeen, of the firm of McMeen & Miller, has taken charge of the preliminary engineering work for the new automatic exchange at Quincy. Underground conduits will be laid in the business part of the city.

ELWOOD, IND.—The Delaware and Madison Counties telephone system in this city is being rapidly extended. There are 122 local subscribers and 67 on farmers' lines.

AFTON, I. T.—The Afton Telephone Co. has had a change in ownership.

OTTAWA, KAN.—The Independent Telephone Co. expects to have its toll line open between this city and Kansas City, Mo., by Nov. 10. The line will be pushed on south into the oil fields.

PECK, KAN.—The Ninnissah Valley Telephone Company has installed a 100-line capacity rural board. It has over one hundred rural telephones.

SPRINGFIELD, MINN.—The Farmers' & Citizens' Telephone Company is now ready for business.

ZUMBRO FALLS, MINN.—The new Zumbro Falls Farmers' Telephone Co. will connect with the long distance system of the Tri-State Telephone & Telegraph Co.

PERSONAL.

A. E. JEAVONS, formerly of Fort Worth, has been appointed local manager for the Southwestern Telephone Company at Waco, Tex., in place of J. W. Henshaw, who resigned.

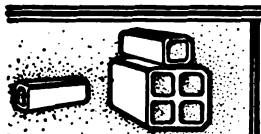
R. P. BERNARD has been appointed manager and secretary of the People's Mutual Telephone Company at Hillsboro, Ill.

UNDERGROUND.

COLUMBIA CITY, IND.—The Farmers' Mutual Telephone Company is making a number of extensions to its plant, which includes a two-cable conduit in the business part of the city.

ROANOKE, VA.—The Virginia & Tennessee Telephone Company will place its wires underground and will also run aerial cable.

RIVERSIDE, CAL.—The Home Telephone Company has commenced building its long distance lines. It has already commenced to install telephones in the city.



New Construction in the Field

CARROLLTON, GA.—The Gainesboro Telephone Company, of this city, is engaged in constructing an additional circuit between this office and Bremen, 12 miles north of here, in Haralson County. Bremen is now reached through Villa Rica. Increased business in adjacent territory to the west and north of Bremen demanded additional facilities.

BLOOMINGTON, ILL.—The Home Telephone Company will commence erecting at an early date new poles to accommodate 30,000 feet of aerial cable in that city.

CLINTON, ILL.—B. F. Wasson, of Clinton, has made a contract with the Interstate Telephone Company for long distance service. The new line will be made with No. 10 copper wire and construction will be of the highest grade.

MUSCOGEE, IND. TER.—The Pioneer Telephone Company has begun work on a new system for this city to cost $50,000 to replace the old system.

DES MOINES, IA.—The Mutual Company is building a new exchange.

HARLAN, IOWA.—The Shelby County Mutual Telephone Company is constructing lines in Harlan.

WEBSTER CITY, IA.—The exchange of the E. H. Martin Telephone Company is being re-built.

MUSKOGEE, IND. TER.—The Pioneer Telephone Company has commenced installing a new flashlight system, and the service will be extended to all parts of the city. A new brick building will be erected, and altogether $60,000 will be paid out by the company in making improvements.

ANTHONY, KAN.—The Southwestern Telephone Company has built a toll line to Duquion, Kansas, to connect with the Kingman Telephone Company.

COATS, KAN.—The Farmers' Mutual Telephone Company has finished its rural system of about fifty telephones.

KIOWA, KAN.—The Kiowa Telephone Company, of which Amas Jones is manager, is building a toll line to the western part of Barber county. This line is being built expressly for the use of the cattlemen.

PRATT, KAN.—The Pratt Telephone Company has completed its toll line to Greensburg, Kansas, a distance of thirt-five miles.

BRIDGETON, ME.—The new farmers' telephone line will be built at once.

ST. JOHN, MICH.—The Grand Ledge Telephone Company will start the construction of its out-of-town lines at once. Among other lines one will be built to Watertown.

DULUTH, MINN.—The Zenith Telephone Company will spend $1,000,000 in improving and enlarging its system.

NEW RICHLAND, MINN.—Henry Jachning will build a telephone line into the country northwest of this village.

NEWPORT, MINN.—The Twin City Telephone Company is putting up its wires through this village.

NEW ULM, MINN.—The Minnesota Central Telephone Company is spending $15,000 on improvements here.

READING, MINN.—The Farmers' Mutual Telephone Company is extending its system.

SILVER LAKE, MINN.—J. J. Greaves, of Glencoe, is installing a new telephone line in this vicinity.

LA GRANGE, MO.—The office of the Lewis County Telephone Company here is being enlarged and improved. The lines are to be gone over and new poles put up where they are needed. This company is growing every day, not only in La Grange, but wherever there is an exchange belonging to the company.

ONEIDA, N. Y.—The New Canastota Telephone Company expects to begin the establishing of its system in that village.

ELIZABETH CITY, N. C.—The telephone line to Weeksville has been constructed.

DEVIL'S LAKE, N. D.—President A. B. Kirlin, of the Devil's Lake Improvement Company, has received a contract from the Indian department of the Interior to construct a telephone line to this city and Ft. Totten.

GRAND FORK, N. D.—The new telephone line to Walcott is nearly completed.

LEONARD, N. D.—The Leonard Rural Telephone Company is constructing several new lines.

CIRCLEVILLE, OHIO.—S. H. Simon will build a local line, which will run to Clearport and adjacent territory.

GALLITZIN, PA.—The Cambria County Telephone Company contemplates installing an exchange in this city.

WORCESTER, PA.—The Montgomery Telephone Company is making a number of extensions to its system and will build lines to Norritonville. This company operates in the heart of a populous farming country, and has progressed to a great extent during the last six months.

CHAMBERLAIN, S. D.—Frank E. Rowe is building a new telephone line south of town. Branches will be extended to Phelps' Island, Okla., and Red Lake Township.

PIERRE, S. D.—Work has been commenced on a telephone system for the Cheyenne River Indian reservation, lines to be run from the main agency, near Forest City, to Cherry Creek, in the southwest corner of the reservation, and to White Horse Camp, in the northwestern corner.

REVILLO, S. D.—The new telephone system at this place has been completed and placed in operation. The line extends to Albee.

FORT WORTH, TEX.—The Fort Worth Telephone Company has about completed its line to North Fort Worth, with a 200-pair cable, making a total of 250 connections to that point. A fine telephone for the free use of the public will shortly be installed in the Texas and Pacific passenger station.

HARTLAND, VT.—The Hartland Telephone Company will commence its work on a new line to extend into West Windsor.

SHUSHAN, VT.—The Granville Telephone Company has nearly completed its new line between East Salem and Shushan, and will make an extension to West Sand Agate.

BOONE'S MILL, VT.—The Franklin County telephone lines are now constructed to the Roanoke County line, awaiting connection with the Roanoke company.

BOOK NOTICES.

TELEPHONY, Part V.—The Substation; by Arthur Vaughan Abbott. McGraw Publishing Company. 473 pages, 310 illustrations. Price $1.50.

This is the fifth volume of a series which treats the subject of telephony in a masterful manner. In all, there are ten chapters, each devoted to some special feature of the substation. The various parts of the apparatus are thoroughly explained and a chapter is set aside for costs of installation and operation. This is a feature that heretofore has received little attention from writers, and is therefore one which would commend this volume to all in need of some definite information upon this important phase of telephony. An important adjunct to this work is a list of twenty tables, which give detailed information upon almost every feature of substation design and engineering. The illustrations are copious and furnish graphic information of every part of the ap-

Digitized by Google

paratus used in the construction, protection and operation of this branch of telephone engineering.

The chapters, with their subjects, are as follows: I, Introduction; II, The Receiver; III, Telephone Transmitter; IV, Induction Coils and Substation Circuits; V, Transmission and Current Supply; VI, Signalling Apparatus; VII, Protection; VIII, Party Lines; IX, Substation Assemblage; X, Cost of Installation and Operation.

To all those interested in the telephone industry we heartily recommend this volume, together with its predecessors, as furnishing a fund of information not to be found in other works of a similar character.

This volume or the entire set can be obtained through the AMERICAN TELEPHONE JOURNAL.

TRADE NOTES.

M. LANZ & SONS, Pittsburg, Pa., are specialists in structural iron work. They have just issued a leaflet, which gives valuable information upon strains and the designs of bolts. This leaflet will be mailed upon request to all parties interested.

THE CENTURY TELEPHONE CONSTRUCTION COMPANY has received an order from the Shinglehouse Telephone Company, Shinglehouse, Pa., for construction material, switchboard and telephones for the new telephone system it is building in that place.

THE CONTROLLER COMPANY OF AMERICA, 1061 Monadnock Block, Chicago, is distributing a handsome and instructive booklet or bulletin describing its new styles of controller apparatus. The company will be pleased to send this bulletin No. 2 to any one not having received it upon the receipt of address.

THE CONNECTICUT TELEPHONE & ELECTRIC COMPANY has placed upon the market a new device for four-party selection signaling, whereby it is possible for stations to call each other without signaling the exchange. This device can be used on any line, and can be adapted to any instruments now in use. By mailing your address the company will send its new No. 8 catalogue, which contains a fund of information.

THE FRANKEL DISPLAY FIXTURE COMPANY, 718 Broadway, New York, wishes to draw the attention of exchange managers to its test clip. As a time saver in clearing trouble it is without an equal service; it gives instant metallic connection with any insulated conductors without injuring the sheathing. The company will be pleased to send a sample hundred which if not entirely satisfactory can be returned at its expense.

THE AMERICAN ELECTRIC TELEPHONE COMPANY has recently sold an additional section to the switchboard of the Topeka Independent Telephone Company, of Topeka, Kansas. The entire equipment for this exchange has been furnished by the American Electric Telephone Company. Since the original installation in 1901 it has been necessary to enlarge the system once ever nine months and is now giving service to nearly 2,500 subscribers.

MESSRS. MCMEEN & MILLER, 1442-1443 Monadnock Block, Chicago, Ill., have complete charge of the construction of the new Independent telephone system which is being constructed at Quincy, Ill. A branch office will be maintained at Quincy, while the work is in operation, and every preparation has been made to complete the system at as early a date as possible. It is confidently expected that several thousand subscribers will be given service within a few months.

THE BENBOW CO., of Philadelphia, Pa., has placed on the market an adjustable disk bracket, which has a number of points of merit. Besides being useful it is strong and durable and makes a nice appearance. Its cost can be made in one year through the saving of expenses in repairing desk instruments, which have been knocked down. This company has built up a large business in this specialty, and is known throughout the country for its honest dealings. It will be pleased to furnish full particulars of this bracket upon request.

FRANK B. COOK, recognizing the fact that there are a great many small exchanges with 50 or 100 lines in use, which are not willing to put their trust in poor protection, has constructed a special protector and distributing frame for their needs called Type "L 3." This frame can be equipped for only ten lines if desirable, and the capacity can be increased in banks of ten pairs of protectors at any time. The Telluride Power Co., at Provo, Utah, has just placed an order for one of these frames, as has also the Northeastern Telephone Co., of Portland, Maine.

THE MORRIS ELECTRIC COMPANY, 4th and Shipley streets, Wilmington, Delaware, begins advertising in this issue a new and meritorious specialty that will be a boon to all telephone managers and installers. It is a cleat made of hard fibre and has been on the market for a short time only. Already, however, the Morris Company has sold thousands of these cleats to both the Bell companies and several large Independent companies. Many of these companies have sent re-orders, and it is generally conceded that this article although small will have an enormous sale, on account of its utility and many advantages. The various styles in which these cleats are made, solve all problems of inside wiring, save much valuable time, and give a neater completed job than can be obtained by any other form of staple or cleat. In addition to being smaller and neater than either wooden or porcelain cleats, the hard fibre cleat is unbreakable and will not split. It can be installed in about half the usual time. They are made with a single groove for twin or parallel wiring; with two grooves for twisted pairs, three grooves for three wires, and a special end groove for corner wiring. They are furnished in either of three colors, black, gray or black, to harmonize with various styles of woodwork, etc. Every Independent company should write for samples and prices on these cleats, as they are a simple remedy for inside wiring troubles. The Morris Electric Company will be pleased to furnish samples and information on request.

WANTED

Advertisements under this head, 25 cents for 25 words or less for each insertion. Prepaid.

WANTED you to know that I can locate your cable troubles. Charges moderate. Address C. E. NICHOLAS, Columbus, Ohio. 226

Bituminized Fiber Conduit
For Underground Construction

Combines the **good features** of other conduits. **Eliminates** the **bad features** existing in many kinds. **Has valuable features** not found in any other ducts. :: ::
Made in 7-foot lengths with male and female joints, making construction very rapid and simple, with consequent low cost. :: :: ::
Alignment is perfect and permanent without tedious care and skill required in laying of butt-joint conduits. Users are astonished by the ease and rapidity with which cables can be drawn in, and this without the slightest scratching or injury to the lead covering thereof.
Made in sizes from 1-inch to 10-inch diameter. ::
Bends of any radius and any angle. :: ::
Write us for further information and prices, stating sizes and quantities required. :: :: ::

American Telephone Practice
By KEMPSTER B. MILLER, M. E.

518 large pages, profusely illustrated with 380 diagrams and cuts of apparatus **$3.00**

A book for the telephone man. It is an encyclopedia of useful information concerning telephony.
It gives complete specifications, enabling you to intelligently order apparatus from manufacturers, and to properly supervise the installation of an exchange, large or small.
It describes in simple language the theory and practice of modern telephony, including circuits, mechanical construction and operation of telephones and switchboards.
A complete description is given of storage batteries, their care and maintenance; of aerial and underground line construction, and, in fact, all the important matters which telephone men need to know.

THE AMERICAN TELEPHONE JOURNAL

Important Notice

With this issue we inaugurate a new department—"In the Manufacturing Field." It will contain from week to week news of all the important new appliances that are being turned out by the manufacturers. It will give information that will be vitally important to every operator in the field.

Also, in this issue, will begin a new system of handling our advertisements. In the back part of the paper the advertisements will be alternated with text pages.

We would like to hear from our readers regarding these new departures.

MR. MANAGER:

Do you ever wonder how you can handle Rural Lines so as to give Subscribers satisfaction at a profit to the Company?

Do you realize that to give Rural Subscribers satisfaction you must, *first of all*, have "Central" answer their first call instantly.

Do you think you cannot do this unless at an increased operating expense?

You can handle more of these lines, by using

The T. & A. Selective "Central" Relay

with the operators you have and give incomparably better service.

Our system is for either Ground Lines, Straight Metallic or "Divided Circuit" Metallic Lines.

You do not have to Purchase New Telephones

WRITE TO-DAY FOR PARTICULARS AND PRICES

The T. & A. Selective Call Co.

Sole Manufacturers GENESEO, ILL.

CONNECTICUT

NON-INTERFERING PARTY LINE SYSTEMS

With our 4-party Selective System, phones can call central without ringing the other bells and central can call subscriber without disturbing the other bells on the line. An up-to-date non-interfering system.

WITH OUR LATEST SYSTEM

the subscriber can call any other phone on the line without calling central, and can call central at will, without ringing any of the other bells on the line.

MAKE YOUR LINE UP-TO-DATE

You can use the apparatus that you now have, with a small change.

SAVES TIME—INEXPENSIVE! AND WILL INCREASE YOUR DIVIDENDS.

Write us at once. Send for our large No. 8 Catalog.

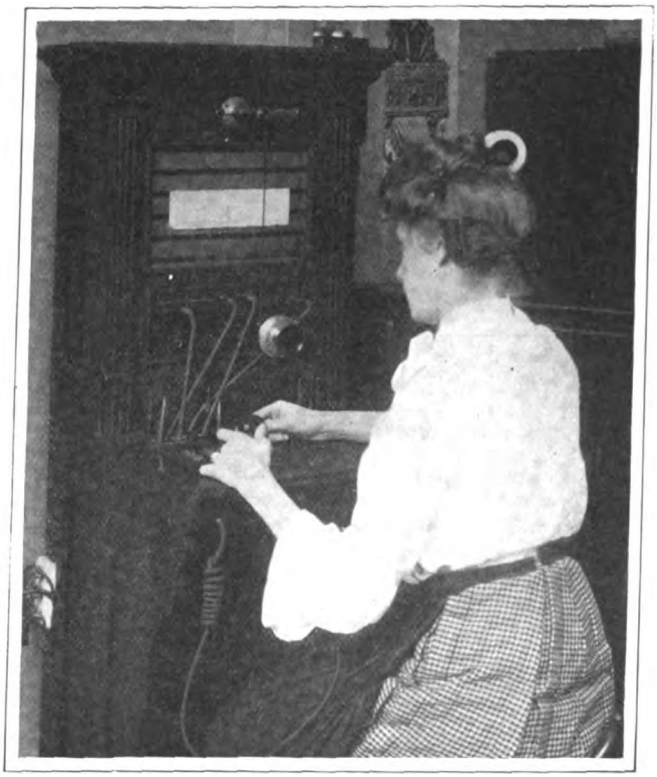
THE PRIVATE BRANCH EXCHANGE AS A BUSINESS BUILDER.

ARTICLE III.—ITS APPLICATION.

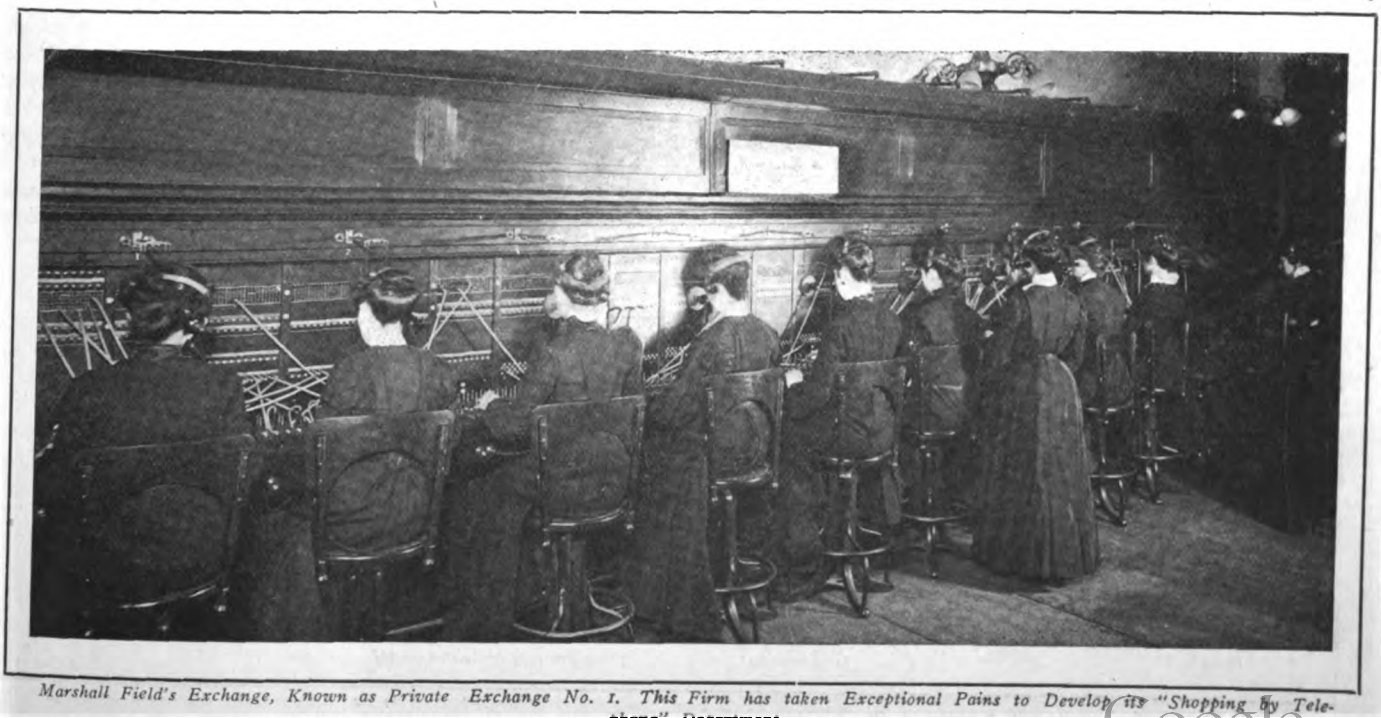
By Thos. W. Francis.

IN the conception of new and novel business methods, Chicago frequently scores a point over Eastern cities. A case in point is the recent adaptation of the telephone to the business of Marshall Field & Company.

To a moderate extent every one has long been familiar with the use of the telephone in certain kinds of buying. It is common practice for one to call up the butcher, baker or grocer, and order sundry small articles, thus saving a trip to the store in question and expediting delivery. But beyond the purchase of the ordinary daily household necessities there appears to be, in many cases, a reluctance to the use of the telephone in the purchase of goods of any kind. Probably this has largely arisen from the difficulty of accurately identifying the purchaser and of subsequently proving that the order was properly authorized in case of a disclaimer on the part of the supposed buyer. As an economizer of time and trouble and an annihilator of space the telephone is well-known, and it is therefore surprising that some astute merchant has not sooner seen the advantage which might accrue to his business from such a telephonic installation as would enable his customers to deal with him, and at the same time properly protect his business interests. Unquestionably the most extensive and successful attempt of this kind is that alluded to as having been installed by Marshall Field & Company in the largest retail store in the country. To begin with, the company installed the largest private branch exchange in the world, equipped with the most modern of switchboards, as shown in the accompanying illustration. This switchboard has fortunately received the designation of "Private Exchange One," which is so easy



Private Branch Exchange of the Indianapolis Tel. Co. Installed at Office of Levey Bros. 20 line capacity 6 cord circuits.



Marshall Field's Exchange, Known as Private Exchange No. 1. This Firm has taken Exceptional Pains to Develop its "Shopping by Telephone" Department.

Digitized by Google

to remember that no one need consult the directory, so that every would-be purchaser picks up the telephone and asks for "Private Exchange One," and almost immediately is in direct communication with the switchboard of Marshall Field & Company's store. Each of the store's exchange operators is trained to be thoroughly posted with all of the sections which Marshall Field & Company's business includes and to know at once the proper connection which should be made to place the purchaser in communication with the division in which the desired goods are to be found.

The success which has attended this method is largely to be attributed to the system, for by training the branch exchange operators so that it becomes unnecessary for the purchaser to ascertain the department desired, and by arranging so that the purchaser is at once connected with the department, satisfaction is immediately insured. Little confusion results in getting the wrong salesmen, and mistakes are obviated by authorizing certain persons in each section to transact all telephone business with customers. By this means the customer is almost always satisfied, but in order to prevent any possible cause of complaint, Marshall Field & Company distinctly provide that they will readily exchange any goods ordered by telephone which may not be entirely satisfactory to the purchaser. In addition to the provision of the best apparatus and careful training of the operators and salesmen, a certain amount of public education is necessary in order that this system should reach its highest development, so a little booklet is prepared, which is widely distributed both throughout the store and to the public. This booklet, which is reproduced in Fig. 2, contains instructions to shoppers indicating the method to be employed when a telephone is used for this purpose. As an example: To purchase a suit of clothes by telephone would seem to be straining the art to the utmost, for it would be seemingly impossible to expect satisfaction from a purchase of this kind.

As a part of their training, both private branch exchange operators and the various department salesmen are required to exercise the greatest politeness and courtesy in all conversation with customers. The reason for this is easy to see, for the slightest brusqueness or abruptness, either in tone or in phraseology, appears to be magnified over the telephone, because one fails to see the facial play which, in many cases, goes far to explain an ameliorated sentence which in its absence strikes the ear harshly. To preserve adequate financial caution telephonic orders are received unquestioningly from those who have a regular account with the firm, while goods to parties who are unknown are sent C. O. D. Thus the worst that can happen is the expense of delivering an occasional order to persons either irresponsible or who subsequently are dissatisfied and refuse to receive the goods.

Private Branch Exchange Installed in the Office of Loveman, Joseph & Loeb, Birmingham, Alabama. This is the Largest Dry Goods Store in the South, and it has Developed a Business Along Lines Similar to those of Marshall Field & Company.

But the experience of the past year has demonstrated that the telephonic system has been a notable factor in increasing trade, and that failures or losses are so small as to be unappreciable. Most cities or towns have many stores that could profitably adopt a system of this kind and thereby markedly increase their circle of customers, particularly among those living in the suburbs.

The Rochester Telephone Company has about 60 private branch exchange subscribers, the largest installation being that in the Powers Hotel that embraces 225 stations. The exchange is equipped with a sufficient number of trunk lines to handle all business outside of the limits of the private branch exchange switchboard. The rates established by the Rochester Company are $10 for each of the private branch exchange stations, $48 for the first trunk line, and $40 for each additional trunk line. Contracts are always made upon a basis of five years, as it is inexpedient to incur the expense of the installation for a less period of time.

In Cleveland, the Cuyahoga Telephone Company serves 87 private branch exchanges containing from four or five to sixty or seventy subscribers. The smaller exchanges of three or four trunks, while those of sixty subscribers have eight or ten trunks. The rates are $12 a year per station, $84 per year for first trunk line, and $72 a year for the succeeding ones.

In Indianapolis, the charges are $40 a year for the trunk lines,

SHOPPING BY TELEPHONE

ONE of the many uses of the telephone is to "go shopping." In a great many cases it is more satisfactory than going in person, because it takes so little time. You call up the store, "Private Exchange-One"—that is easy to remember—and ask the operator for the section you wish to speak with. Tell the salesperson what you want, and he will tell you what it costs and how it comes, and when you may expect it. If you haven't an account the goods may be paid for when delivered. ¶ Owing to the growing custom of making purchases by telephone, we have made special provision in every section for prompt and intelligent attention to telephone orders.

MARSHALL FIELD AND COMPANY
(Retail Store) CHICAGO

The Art *of* Telephoning

Telephone
"Private Exchange-One"

PERHAPS more than aught else the telephone quickens the pace of progress. As a factor in social and commercial life its importance can hardly be overestimated. Undeveloped possibilities await public appreciation. Notwithstanding its extensive use, few realize the endless ways it can serve them. ¶ The telephone makes moments do the work of hours. It cancels distance, delay, formality, and superfluous conversation. Dropping the husk and the shell, it deals with the kernel of intercourse. It concentrates thought, brings out the essential points, and makes a complex problem a simple one. It penetrates the panoply of rank, and gains the ear of seclusion. While many await an interview, its message receives consideration. It changes plans, gives sanctions, secures counsels, and grasps opportunities. It places the commercial forces of a metropolis at your call. ¶ A system which makes possible these things is a marvel of mechanism, a knowledge of which silences censure with admiration and awe. A moment's delay is easily forgotten amid gratitude for the high privilege of telephoning at all. An hour at the operator's desk would beget a kind and courteous sympathy for unsuccessful effort.

MARSHALL FIELD AND COMPANY

Reduced Fac-simile of a Folder Distributed by Marshall Field and Company to Draw Attention to its "Shopping by Telephone Department."

Digitized by Google

$30 for one-way lines, and $10 a year for stations within 500 feet of the switchboard, $20 for those between 500 and 1,000 feet, $30 where it is necessary to use conductors either upon pole lines or in conduits. Fifty-eight exchanges are in operation, varying in size from seven stations, with two or three trunk lines to 400 stations and a dozen or fifteen trunks.

The Keystone Company of Philadelphia is recording 160 private branch exchanges. Trunk lines bear a tariff of $60 per year, and the stations $12. It is estimated that about 12 per cent. of the entire traffic of the company is handled by private branch exchanges. The smallest station has eight subscribers, while the largest one accomodates over 300.

The Toledo Home Telephone Company lists 44 private branch exchanges averaging from ten to fifteen subscribers each. The number of trunk lines varies from one, where four or five subscribers are served, to five, where there are from 25 to 30 subscribers. Rates are $12 a year for private branch exchange stations and $48 for the trunk lines.

Mr. A. L. Teto, of Louisville, informs us that the Louisville Telephone Company now has about 50 private branch exchanges operating on the basis of $12 per station and $48 for trunk lines. Mr. Teto points out a notable feature in private branch exchange service in the avoidance of busy reports. By means of the branch exchange, the desk of every employee may be equipped with a telephone and consequently can answer calls immediately, otherwise it is often necessary to send from one part of the building to the other in order to get a desired correspondent to the telephone. Such procedure results in tying up the lines, and largely increasing the percentage of busy calls. The private branch exchange obviously entirely avoids this.

The Springfield-Xenia Telephone Company, of Springfield, O., has six branch exchanges. The rates are, for trunks, $36 per year and substations, $12.00 per year. These exchanges have capacities varying from four to eighty stations and from one to three trunks.

IMPEDANCE AND RETARDATION—ARTICLE VI.

By Arthur Vaughan Abbott.

IN the immediately preceding articles of this series, a rough outline has been given of the behavior of circuits which contain inductance and capacity in addition to simple ohmic resistance. In telephony, inductance and capacity play a far more important rôle than mere resistance. For example, one can easily talk through a lead pencil mark, aggregating several million ohms, but it is different to talk through a 500 ohm drop. To put a con-

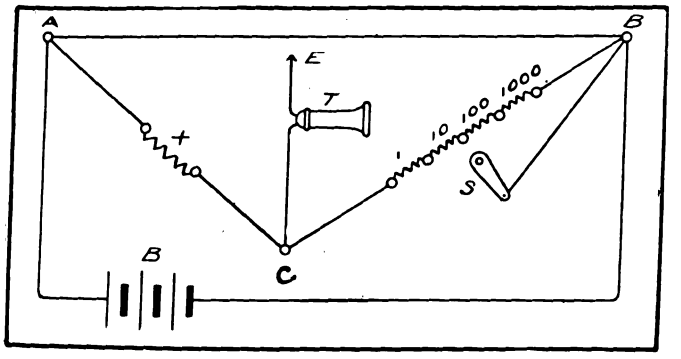


Fig. 11.

denser in a lighting or railway circuit, would be to put the plant out of commission, but through a condenser made of a couple of pennies and a bit of paper, conversation may be carried on with reasonable facility. So it is desirable for those who are in constant contact with telephonic apparatus to know the various methods whereby inductance and capacity may be measured and to cultivate some sense of familiarity therewith, and such a knowledge of the effects which they produce, as is possessed by nearly every electrician with regard to ohmic resistance.

In the construction of induction coils and retardation coils, inductance is the prominent feature, and mere ohmic resistance cuts but a very small figure. Installations which employ common battery or use automatic signaling must use condensers at the substations, and in many switchboard circuits condensers are introduced for the purpose of improving transmission. In the problem of bettering transmission over long lines, the relative proportions of inductance and capacity are to the last degree important, and success depends upon their mutual adjustment. In most cases manufacturers supply apparatus which, from their point of view at least, is best calculated for the purpose it is designed. Usually operating companies content themselves with taking such appliances as are readily obtained in the open market, and pay very little attention to the possibility of improvements. Nevertheless, telephony as an art is constantly and rapidly progressing and those who desire pre-eminence must be thoroughly posted in the relations of all fundamental principles and be able to carry on such investigations as may lead to improvement.

In a circuit containing ohmic resistance, it has been shown that the relation between current, electromotive force and resistance are given by the formula $C = \frac{E}{R}$

Also, it has been shown that if inductance be added, the formula must be modified to read $C = \frac{E}{\sqrt{R^2 + 4\pi^2 n^2 L^2}}$, in which n is the frequency or number of alternations per second and L

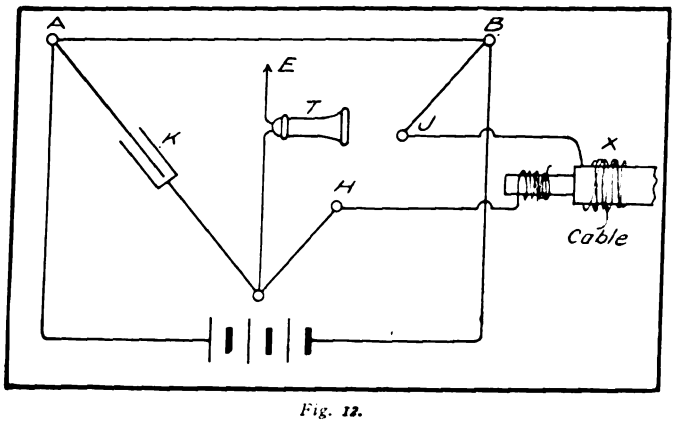

Fig. 12.

is called the coefficient inductance. That is to say, the ratio of the number of magnetic lines which are enclosed by the circuit to the current which produces them.

For, according to the C. G. S. system, a unit current is one which, flowing in a circuit of 1 cm. radius, acts on a unit magnetic pole placed at the center of the circuit with one unit force, that is generates one line of force. For example, consider a circuit bent in the form of a ring of 2 cm. in radius, carrying two units of current. As the circuit is 4 cm. in diameter, the length is 3.1415 $\times$ 4 = 12.56 cm. As there are two units of current there will be 12.56 $\times$ 2 = 25.12 units of force or magnetic lines to act on a magnet placed at the center of the circle. As there are two units of current the ratio of the lines of force produced by the current to the current is $\frac{25.12}{2} = 12.56$, hence $L = 12.56$.

In a circuit containing capacity, the relation between cur-

Digitized by Google

rent and electromotive force is expressed by the formula

$$C = \frac{E}{\sqrt{R^2 + \frac{1}{4\pi^2 n^2 K^2}}}$$

In the preceeding equations there are the following quantities:

C = Current.
E = Electromotive force.
R = Ohmic resistance in ohms.
L = Inductance in henrys.
K = Capacity in farads.
N = Alternations per second.
$2\pi = 6.28$.

Now, if in either equation four of these quantities are known,

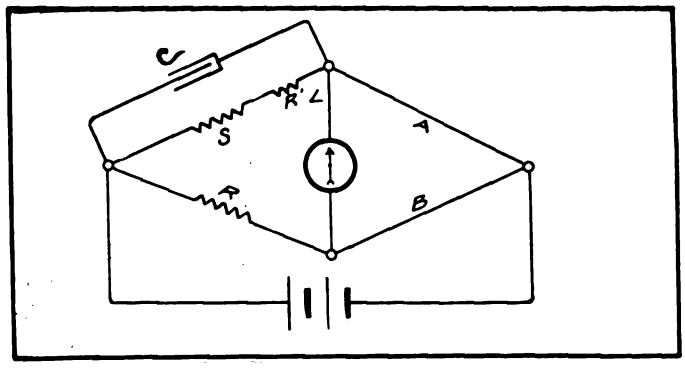

Fig. 13.

or can be measured, the remaining one can be determined. Thus, knowing the current electromotive force, resistance and frequency, the inductance L is given by the expression: $L = \frac{\sqrt{E^2 - C^2R^2}}{6.28\ n\ c}$

And for a circuit containing capacity $K = \frac{C}{6.28\ n\ \sqrt{E^2 - C^2R^2}}$

Passing now to the various methods which may be employed in measuring both inductance and capacity, the most convenient one is that using a slide wire bridge, or what is now more popularly known as an ohmmeter. The circuit of the ohmmeter is shown in Fig. 11, in which $A\ B$ is a uniform wire of known resistance. To the points A and B a source of electromotive force B is attached. In the illustration this is represented as a conventional battery, but when it is desired to make measurements on inductances or capacities, alternating current must be substituted for the battery. If an ordinary alternating lighting circuit is available, it provides a very convenient source of electromotive force. Take a piece of lamp cord from 20 to 25 feet in length. To one end of the cord attach a plug which will fit any of the lamp sockets. At any place in the cord, introduce a lamp socket, into which a 16 candle-power lamp is placed. Then provide each of the ends of the cord with a terminal made by peeling off the insulation and dipping the wire in solder, thus enabling the cord to be attached to A and B. By inserting the plug into a lamp socket, the lead is attached to the electric lighting mains, while the presence of the lamp provides a resistance that will prevent accidents in case the terminals should be unintentionally short circuited. From terminals A and B, the conductors $A\ C$ and $B\ C$ extend. Conductor $A\ C$ contains two binding posts, between which the inductance or capacity to be measured may be inserted. In conductor $B\ C$ standard resistance coils are shown. These are used in measuring resistance. But for induction or capacity tests these coils must be removed and a standard inductance or condenser, as the case may be, substituted. Then all that is necessary is to insert the unknown inductance or capacity between the terminals at X, set the switch S so as to include such a standard in $B\ C$ as appears to be best suited for the range to be measured, slide the point to and fro over the wire $A\ B$ until no sound can be perceived in the receiver T. The point E will then divide the wire $A\ B$ into two segments, $A\ E$ and $E\ B$. X is then equal to $A\ E$ divided by $E\ B$, multiplied by the standard in $B\ C$.

Fig. 12 shows another circuit for measuring capacity. Here a condenser of known value is introduced at K in place of X, shown in Fig. 11. The unknown capacity, which may be cable or any other piece of apparatus, is introduced in $B\ C$, and then the contact E is moved to and fro over the wire $A\ B$ until no sound is heard in the telephone and the amount of capacity calculated as above.

Perhaps the ohmmeter is unobtainable and it may be necessary to use the ordinary Wheatstone bridge. For this purpose the bridge should be arranged as is shown in Fig. 13, in which A and B are the rheostat arms of the bridge, R the variable arm, S a variable non-inductive resistance and $R'\ L$ the inductance to be measured, of which R' is its ohmic resistance to a continuous current previously measured, and L its inductance to be ascertained. C is a condenser placed as a shunt across the arm of the bridge, in which S and $R'\ L$ are inserted in series. The object of S is to bring the capacity required to balance the inductive resistance within reasonable limits. The balance is obtained by adjusting the mutual values of C, S and R until no deflection is produced on the galvanometer when the battery circuit is interrupted. Under these circumstances if A and B are equal, the value of L is found from the expression $L = C\ R^2$, in which R^2 is equal to the sum of S and R'. The value of this method may be extended over greater ranges by giving A and B any desired ratios, as in ordinary bridge measurements. The auxiliary resistance S is required to adjust the capacity within reasonable values to balance the inductance. If, for example,

L has a value of 4 henrys.
R' has a value of 10 ohms.
C must be equal to .01 of L, or 4,000 M. F.

Such a capacity would be beyond ordinary apparatus. By increasing R' to 1,000 ohms by the addition of the adjustable resistance S, C becomes equal to .4 M. F., an easily obtainable capacity.

A slightly different method than the preceding one is sometimes desirable for some forms of bridges. The diagram of the circuit is shown in Fig. 14, while Fig. 15 is a top plan of a bridge with all the connections made for measuring inductance, in the manner about to be described. In these illustrations, K is a condenser of known value, which may or may not be adjustable, A and B the ratio arms of the bridge, R the rheostat and R' the coil whose self-induction L is to be measured. Shift the contact along R, using the battery key Ba and the galvanometer key Ga

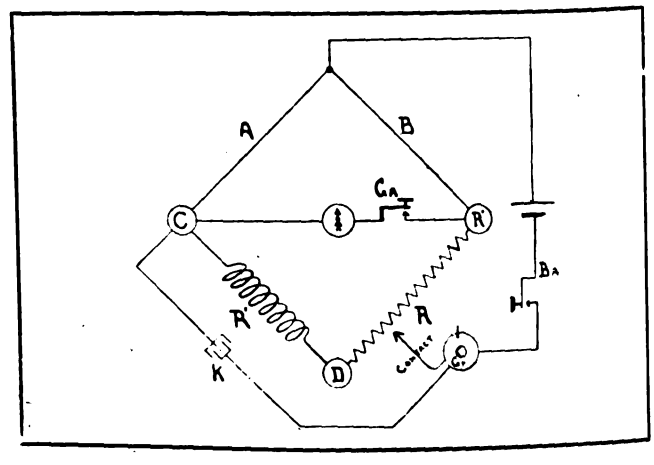

Fig. 14.

in the usual manner and then by breaking the battery circuit first. Every time the keys are closed, the galvanometer needle will momentarily deflect. The deflection will be in one direction if the quantity of the electricity discharged by the condenser is larger than that discharged by the circuit containing the inductance R'.

When the contact is shifted so as to reverse these conditions, making the quantity discharged by the coil greater than that dis-

Digitized by Google

charged by the condenser, the throw of the needle will be in the opposite direction, and finally when these quantities are equal, the galvanometer needle will remain at zero when the battery circuit is broken. The addition of the non-inductive resistance R cuts down the discharge from inductive resistance R', while the discharge of the condenser would be lessened by a decrease of its capacity, consequently by manipulating the relative proportions of the condenser K and the resistance R a balance can be secured.

Consider, now, the circuit $R + R'$ (which does not contain

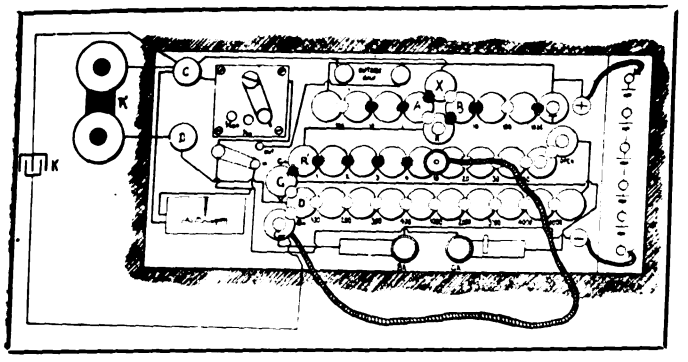

Fig. 15.

capacity), the coefficient of self-induction L, is given by the expression:

$$L = \frac{Q\ (R + R')}{C}$$

where Q is the quantity discharged on break of the battery key and C is the current.

Similarly the quantity discharged by the condenser is expressed by

$$Q = E\ K,$$

where E is the E. M. F. to which the condenser is charged.

When these quantities are equal (i. e., when balance is secured) we may substitute $E\ K$ for Q in the first equation and write:

$$L = \frac{E\ K\ (R + R')}{C}$$

But $C = \frac{E}{R + R'}$, whence

$$L = K\ (R + R')^2.$$

There is another method of measuring inductance when a current of known frequency is available, and an alternating current voltmeter and ammeter, and an adjustable non-inductive resistance. The apparatus is set up in such a way that a current of known frequency may flow through the inductive resistance to be measured and the adjustable one in series. The necessary measurements then consist in measuring the fall of potential E with the alternating current voltmeter around the inductive resistance of which the inductance is desired, and the amount of current C with the ammeter. A continuous current is substituted for the alternating current and the non-inductive resistance adjusted till the current of the same value C as was formerly used with the alternating current. Then the drop E' over the inductive resistance is measured by the voltmeter. Then the inductance L is found by solving the equation:

$$L = \frac{\sqrt{E^2 - E'^2}}{2\ \pi\ n\ c}$$

This method is subject to error, due to the current taken by the voltmeter, which must be of sufficiently high resistance as to make the current legible.

The preceding method may be employed to measure the coefficient of mutual inductance M, of two coils. Let R_1 and R_2 be the respective ohmic resistance of the coils, and L_1 and L_2 the respective coefficients of inductance. First connect the two coils in series, and measure the total inductance by the above method, obtaining a value denoted by L'. Then connect the coils in opposition, and again measure the total inductance, and denote the quantity thus obtained by L''. Then

$$L' = L_1 + L_2 + 2\ M.$$
$$L'' = L_1 + L_2 - 2\ M.$$
$$M = \frac{L' - L''}{4}$$

The following method can be used for measuring mutual inductances when a galvanometer and a battery alone are available.

Arrange a circuit, as indicated in Fig. 16, in which the first coil A is placed in series with the key K, and the battery P, and resistance R_1, while the second coil B is placed in series with the galvanometer G, and the resistance R_2. Between the points a and d a condenser C is placed as a shunt. The other extremities b and c of the resistances R_1 and R_2 are placed in series. Opening and closing the key K produces currents in the coil B, giving deflections on the galvanometer which are proportional to $M - C\ R_1$

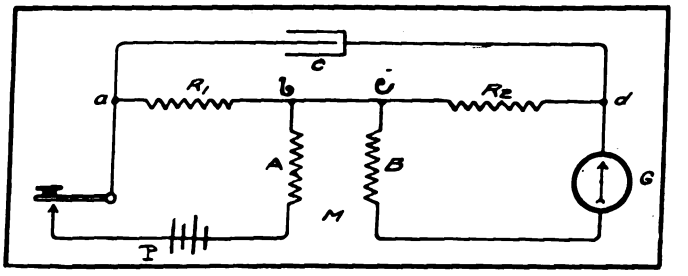

Fig. 16.

R_2. By varying the capacity of the condenser, different deflections d and d' are obtained, which have the following relation:

$$\frac{M - C\ R_1\ R_2}{d} = \frac{M - C'\ R_1\ R_2}{d'}$$

in which C and C' are the different condenser values, and d and d' the different corresponding deflections, from which the coefficient M is obtained by equation:

$$M = C\ R_1\ R_2,$$

when d reduces to zero.

A CABLE RECORD SYSTEM

By Harold A. McMann.

THE advantages to be derived from the possession and use of a compact and simple cable record system are obvious.

The following is a description of a system that has recently come within range of the writer's observation which appears to possess much merit.

The first diagram (Fig. 1) represents a filing card; this may be designated as an individual cable record card. The heading of the card gives the number of the cable, the exchange district and the street on which the cable runs.

The first and second columns note for the different sections of the cable, either between each pole or between each cable terminal; the latter is to be preferred, as hardly any benefit would be derived from showing the lengths between each pole.

The third column is for the length of the section. In the fourth

Digitized by Google

column the size of the cable in pairs may be shown and the gauge of wire in the fifth column.

The sixth column shows the various pairs which end at the different terminal poles.

Fig. 2 shows a summary card, and is designed for the totals of the items contained on the cards as shown in Fig. 1. The numbers

CABLE NO. 3 IN THE Bradford DISTRICT
ON Decatur STREET

SECTIONS FROM	SECTIONS TO	LENGTH	SIZE	GAUGE	PAIRS
Cent. Office	Pole 3	297'	25 pair	#22	1 to 25
Pole 3	Smith St.	303'	" "	"	10 to 25
Smith St.	Hicks Ave.	250'	15 "	#19	1 to 15
Hicks Ave.	Barrow St.	275'	" "	"	1 to 15
Barrow St.	Pole 32	230'	10 "	"	16 to 25
Pole 32	Johnson Ave	260'	" "	"	5 to 14
TOTAL		1615'			

Fig. 1.

of the cables are put down in the first column, then following are columns for the subdivision of the cables according to their size. At the right hand a column is added for brief remarks, such as the condition of the cable, etc.

The usual method of using these cards is to arrange them in numerical order, the individual cable cards, as shown in Fig. 1, in a convenient box; one set, of course, being used for each exchange district. Then after the last card a summary card is inserted.

Thus all the details of any particular cable in a district may be obtained from the first cards, and the record of cables for a whole district in their entirety from the summary card.

SUMMARY OF CABLES IN Bradford DISTRICT

CABLE NUMBER	10 PAIR	15 PAIR	25 PAIR	50 PAIR	REMARKS
1	300'	285'			Good condition
2					Taken down on August 18th 04
3	490'	525'	600'		Poor
4			250'	425'	O.K.
TOTAL	790'	810'	850'	425'	

Fig. 2.

This system of keeping account of aerial cables is particularly convenient for obtaining tabulations necessary for construction of an inventory—the bugbear of average telephone man.

With slight alterations or modifications the above system could be used for underground as well as aerial cables, thus furnishing a very compact system of reference.

The Telephone in the Courts

Conducted by A. H. McMillan.

Readers are invited to submit questions on any point of Telephone Law. They will be answered and explained on this page.

SUBWAY COMPANIES NOT COMMON CARRIERS,

AN electrical subway company is not a common carrier and therefore not bound to furnish the use of the subway to all alike, but may withdraw the use of the subway from anyone who refuses to pay for the same. This was held by the Supreme Court of New York to be the law in a case in which the Consolidated Telegraph and Electric Subway Company of New York, constructed subways in the city streets under a contract with the Board of Electric Subways. The defendant agreed that space in the subways should be leased to any corporation having power to operate electric subways in the city and to fix a fair scale of rent to be charged for the use of such subways, scale of rents to be subject to the control, modification and revision by the Board of Electric Control.

An Electric Illuminating Company inquired what were the defendant's rates for the use of the subway, and upon being informed, presented the Subway Company with a written application for space in the subway for one year. The Subway Company did not sign any agreement and did not agree to allow the other company to continue the use of the subway for any specified time. The Illuminating Company did not pay any rent for the subway or continue to use it until the Subway Company threatened to deprive it of such use, when the Illuminating Company applied to the courts for an injunction to restrain the Subway Company from withdrawing the use of the subway. The Illuminating Company claimed that the rates fixed upon by the Subway Company were unfair.

The court refused to grant an injunction, holding that the determination as to whether the rents fixed by the defendant were fair and reasonable was for the Board of Electrical Control, and when it has passed upon the question its decision was final and not reviewable in the courts. It was further decided that the acceptance by the defendant of the Illuminating Company's application and giving verbal permission to use the highway was a mere license to use it for the period mentioned, and that the defendant might withdraw the use of the subway at any time.

Brush Electrical Illuminating Company vs. Consolidated Telegraph and Electrical Subway Company, 15 N. Y. S. 81.

DURATION OF CONTRACTS.

A CONTRACT between the Western Union Telephone Company and the Pennsylvania Company, a railroad corporation, provided for the construction, maintenance and operation of a telegraph line along the right of way of the railroad company, which was to furnish and place the poles and cross arms, while the telegraph company was to furnish the wire insulation and instruments, and operate the line, sending messages relating to the railroad business free, and having itself the commercial business. The railroad company was given the right to string a wire for its own business, and the telegraph company an additional wire, and provision was also made for the repair and renewal of the line. The line was built and operated under the agreement for many years, during which time it became an important part of the general system of the telegraph company, which by mutual agreement largely increased the number of its wires, and parol modifications were also made as to the expense of repairs and reconstruction.

QUERIES

Questions on any subject relating to telephony will be answered on this page.

CONNECTING COILS OF MAGNET.—(446.)

In winding the coils for a telephone ringer magnet, are the coils connected together, as in the following diagram; A, A being the inside ends of the windings and B, B the outside or finishing ends; or is A of one coil connected to B of the other evil? H, H represents the hinges on the cover of the box. If you will kindly answer the above you will greatly oblige.

D. H.

If the current flows in a coil so that when facing the end of the magnet and tracing the direction of the current it circulates with the hands of a clock, that end is a south pole. If the magnet is properly connected it will have a north pole at the other end and the current circulate in the opposite direction. Tracing the

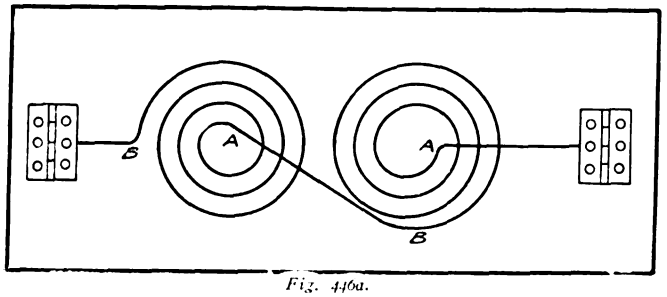

Fig. 446a.

direction from hinge to hinge, as given in Fig. 446a, similar poles would result, therefore it is evident that *A* of one coil must be connected to *B* of the other to get opposite poles.

Fig. 446b illustrates the parts of a magneto bell and generator, *N*, *S*, being the permanent magnet of the generator; *P*, *P*, the pole pieces, and *A* the armature. *N'*, *S'*, are the poles of the permanent magnet of the ringer; *f*, *e*, the sofe iron poles, and *y* the yoke. The connections between the armature of the generator and the coils are plainly discernable and need no further explanation.

AN OPERATING QUERY.—(447.)

We have an exchange of 600 subscribers, 70 per cent. residence; daily traffic averages 4,000 calls. During the past year we have been trying to pursuade the subscribers into calling by number. With few exceptions we have secured this result. Our method has been to have all operators ask parties calling by name if they know the number, if not, the operator connects the calling party with the information operator who then gives the subscriber the number of the party wanted. The party then has to get his operator and give the number in the usual way. This puts a suggestive drag into the service. The subscribers are dissatisfied with this arrangement. They claim that an operator can easily memorize the number most frequently called and that they should be allowed to extend this courtesy to the subscribers. Can you give me your opinion as to the best policy to pursue, either allowing the operator to connect when she knows the number or to putting all calls by name onto the information operator and not oblige the operator to burden herself with this inforination. G. D. W.

The situation you describe is a very common one in rural communities, and unfortunately it is often difficult, without a great deal of diplomacy, to compel the subscriber to call by number. Calling by number is the only way that calls should be made. In the first place, where calling by name is tolerated a great deal of flexibility is lost in the traffic department. Operators cannot be changed from positions on account of lack of knowledge of names; and again it is very difficult to break in a new operator. On the other hand, the drag to the service incidental to transferring calls to the information clerk is undesirable, especially where the subscriber has to call his operator over again. We would suggest your placing a notice to the effect that all calls must be made by number, explaining the reason and, if necessary, cards could be supplied upon which subscribers could mark all the numbers called most frequently. A good plan to save delay when a number is desired of the information operator, and the one most generally used, is to wire up all the operators' receivers to separate call wires ending in buttons at the information desk. Then when a party desires the information operator for a number she can tell them direct and at the same time go in on the order button connected with the operator's position which originated the call and tell her to give the connection. As an example: Suppose a call is received from 302 in position, 2 asking for Mr. Smith. The operator would give the party the information operator, who would then tell the caller Mr. Smith's number (346) and at the same time go in on the circuit to the operator at position 2 and say, 346 for 302, or else 346 for—giving the number of the information trunk to which 302 is connected.

CONDENSERS.—(448.)

Will you please explain to me about a condenser, the various kinds, etc. Are there any different kinds made? Why are some bridged and some cut in series? Is there a noise condenser? J. W. R.

To answer your questions regarding condensers in full would require a complete treatise on electricity. It is only practical for us to briefly state that when any conductor is connected with a source of electricity, the conductor acts as if it absorbed or retained a portion of the electricity and so the conductor is said to possess capacity. The quantity of electricity which a conductor can absorb depends upon the shape of the conductor and the insulating material with which it is surrounded. The larger the service of the conductor, the greater the quantity of electricity which it can absorb. Various insulating substances also possess different powers of absorption, which is usually termed specific inductive capacity, and further the amount of electricity which can be absorbed is inversely proportional to the thickness of the insulating material. Condenser is a contrivance that is made to absorb electricity and usually consists of two thin sheets of metal such as tinfoil which are separated by an insulator, such as a piece of paper impregnated with paffin. So telephone condensers are made from two long sheets of tinfoil rolled into a flat package, which is separated by a strip of paper.

Another form of condenser is the leyden jar, which is simply a glass jar bottle, coated on the inside and outside, which operates in precisely the same manner. An alternating current cannot

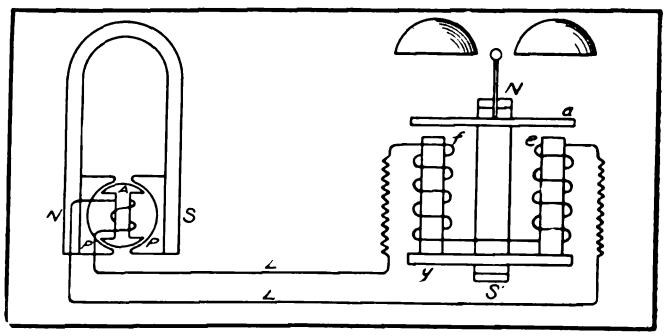

Fig. 446b.

pass through a condenser, but a continuous current is enabled to. Hence, the chief use of a condenser in telephony is to open a telephone circuit to a continuous current, such as is given by a battery while allowing the alternating current of the transmitter to pass through it. For this reason condensers in telephony are almost invariably used in series with the line and are very rarely if ever bridged.

We do not know what you mean by the term a noise condenser, and therefore we are unable toanswer this part of your inquiry.

"OUR BIASED AND NARROW EDITORIALS."

THE management of this paper has in the past had more or less to say concerning the loyalty of its subscribers. We have endeavored to accept this loyalty in a modest, if grateful spirit, and it is our hope that we have not been led to boast of it unduly. It is undeniable, however, that we have been much gratified by the remarkable fact, said by competent authorities to be almost without parallel, that in the last three years we have had less than two dozen discontinuances. Without exception, even these few discontinuances were based on fair reasons. This man had gone out of the telephone business and had no further use for a telephone paper; the other had transferred his services to a new telephone company which was already taking the paper; here and there two or more companies were consolidated, and therefore they consolidated their subscriptions.

In view of this general condition, we were considerably shocked recently by the receipt of a request from the secretary of a small but prosperous telephone company in Illinois, asking that we discontinue his paper and giving the following reason for his action:

> "I think your editorials biased and narrow. While I am Independent and always have been, I think it better to look for methods of better conducting our own business than to harangue a competitor whom in the same breath we call a dead letter."

This statement strikes us as so extraordinary coming from a man whose battles we are fighting that we deem it advisable to make formal answer in these columns. We will, therefore, endeavor to justify our position to this gentleman by detailing the facts connected with a recent transaction of the Bell Telephone Company in the State of New York.

During the past two years the lethargy which had previously characterized Independent telephone development in the East, began to give way before what the Independent Consolidated Telephone Company, of Wisconsin, in a recently issued prospectus describes as the "active missionary work carried on by THE AMERICAN TELEPHONE JOURNAL." "As a result of this missionary work," continues this prospectus—

> "The eyes of the Eastern people are finally opened, and Independent telephone promotion is being pushed at a rate that promises to rival the intense activity of the Middle West. A list of thirty-four towns in Western New York outside of Buffalo shows an aggregate list of 21,585 Independent subscribers as against 12,150 Bell subscribers.
>
> "The city of Buffalo now has an Independent exchange of nearly 6,000 subscribers."

This statement on the part of the Wisconsin company, which, in so far as it applies to the number of Independent telephones, is very conservative—for there are nearer 50,000 than 20,000 in the western part of New York State to-day—would seem to furnish a sufficiently strong proof of the wisdom of our editorial course. But, it may be contended, it does not justify "biased and narrow" editorials. No amount of Independent development or industrial development of any kind can justify a biased and narrow editorial course. The question then is, has the course of THE AMERICAN TELEPHONE JOURNAL been biased in its attitude towards the Bell? A graphic answer is to be found in the recent transaction alluded to.

At Johnstown and Gloversville, two of the most thriving places in Fulton County, New York, the Glen Telephone Company had built up through good service and low rates a telephone system that promised to be one of the strongest in the State. It had practically driven the Bell out of business and was giving service to something over 3,000 subscribers. The Bell exchanges had virtually nothing left, except a little long-distance business. The Bell apparatus, as is usual in places of this character, was antiquated. The sympathies of the people were with the Independents, and this, taken in connection with the wretched service offered by the Bell, left the old-time company in a hopeless position. In other directions, also, the Bell Company was being seriously menaced. Throughout the section of the State adjacent to Fulton County, Independent lines are growing up at a rate that is amazing. Independent long-distance connections are being steadily pushed towards Gloversville and Johnstown, and there is building up a system of telephones on all sides that promised to give the Glen Company so many connections that all hope of the Bell re-establishing itself was out of the question.

ALL INDEPENDENTS SHOULD READ THIS.

At this stage the Boston gentlemen, who direct the destinies of the Bell enterprises throughout the country, executed a coup. Almost over night they effected a "consolidation" with the Glen Company. By the terms of this consolidation, the Hudson River Bell, which controls that territory, agreed to withdraw from Johnstown and Gloversville and turn over all its business and apparatus there to the Independent. The conditions attached to this consolidation were that the Glen Company should substitute Bell transmitters and receivers and agree to turn over all its long-distance business to the Bell.

The method by which this "consolidation" was effected has not been made public. Naturally the gentlemen who control the interests of the Glen are not disposed to give away their private business affairs. They profess to be thoroughly satisfied with the bargain, and say that it relieves them of the danger of a rate war, which the Bell had threatened. Be that as it may, so far in this transaction no one had any right to complain of either of the parties. If the Glen Company's stockholders chose to get away from the Independent alliance and tie themselves to the Bell, that was their own affair, provided, of course, they can justify their course to their subscribers and to the public that granted them the franchise in Fulton County with the understanding that they would protect the citizens against the exactions of a monopoly. But having effected this deal, the Bell people are pursuing a course that *does* give honest people the right to complain, even at the risk of being classed as biased and narrow. This course is one usual with the Bell in cases of this kind, and consists in spreading broadcast misleading statements of the transaction. These statements are presented in those papers in Western New York that are willing to sell their reading columns for a price. Among others of these purchasable papers were the Utica (N. Y.) *Press*, the *Union*, of Dunkirk, and the *Palladium*, of Oswego. The *Palladium* unfortunately committed a little indiscretion. In that paper the matter appeared in the shape of an editorial, but at the bottom was the fatal hall mark:

oct17d1t

This hall mark reveals to the initiated that this alleged editorial was to be published in the "daily of October 17th, one time." The Utica *Press* was more discreet and more dishonest towards its readers. It published the article in the shape of a dispatch under a New York City date line. The Dunkirk *Union* was equally dishonest towards its patrons by publishing the matter as an alleged local article, without marks, so that its readers, of

Digitized by Google

course, accepted it as legitimate news matter. In all three of these papers, however, the editors were so slothful and inapt that they did not take the trouble to alter a single word, nor even to differentiate in the paragraphing of the matter.

It is unnecessary to produce this statement in full or to answer it at length, but it may not be amiss to assure our friends of the Bell that there is anything but a feeling of panic among the Independent interests operating in New York State on account of this transaction," as these corrupted newspapers set forth. On the contrary, the transaction has cemented the several loose ends of the Independent business in that section of the State, and has strengthened the feeling of co-operation that in the past has not been as strong as might be desired among the various Independent organizations. It has also brought into active interest a strong group of capitalists who have large Independent holdings that have proved profitable to them. These gentlemen have begun a campaign, the result of which is going to be somewhat startling to the Bell promoters. Already plans are under way to surround the towns of Gloversville and Johnstown with the strongest telephone service known anywhere in the country. Literally, every hamlet and every farmhouse will be equipped with an Independent instrument, and before long the business men and residents of Johnstown and Gloversville will find themselves under the necessity of throwing out the telephones controlled by the Bell interests or else permitting themselves to be cut off absolutely from communication with their immediate neighbors, on whom they must depend for support. Instead of weakening the Independent situation in New York, this deal on the part of the Bell will serve to make it stronger than it ever was before. It has aroused the fighting blood of a company of men, who in their fields have demonstrated what they can do in competition; men with unlimited means and unbounded energy; men who have shown themselves masterful executives; who, wherever they have come in competition with the Bell have invariably triumphed, and who have built up systems not only in New York State but elsewhere that are models of their kind. These men have created exchanges in the greatest strongholds of the Bell, exchanges that are paying substantial dividends and are now giving ten connections where the Bell gives one. These men are not hunting a fight. But neither are they running away from one, and when they have a situation like this thrust upon them, they will meet it in a way that will ultimately result in putting the Hudson River Bell Telephone Company where the Michigan, the Erie and the Central Union were landed. These three great Bell concerns were foolish enough to pursue in the West somewhat the same tactics that the Hudson River is now pursuing in the East. They wound up bankrupt. If the eastern Bell corporation escapes a similar fate, it will be because its officers are clever enough to saddle their troubles on foolish investors in their stocks, and still more foolish Independent companies who are short-sighted enough to enter into "consolidation" deals.

"Owing to the broad lines on which it is building up its business," recites the paid article from which we have already quoted above, "the Bell Company ultimately is going to triumph over its rivals," and the Independents are all going to be down and out. Even at the cost of being considered "biased and narrow," we venture modestly but firmly to doubt this. We venture to point those who reason along this line to a short but significant statement made recently by Henry Clews, the well-known financier, in an article in the *Cosmopolitan Magazine*. Discussing "Wall Street's Wild Speculation—1900 to 1904," Mr. Clews winds up by saying:

> "But meanwhile one bad sign is noteworthy: The large corporations being unable to market new bond issues, are borrowing heavily from banking syndicates at .ve to six per cent. on notes running from one to three years. There is danger in this, and the way of the borrower on these terms may, like that of the transgressor, be hard."

The American Bell Telephone Company in its sore need to support the campaign that many of its constituent companies are conducting on a losing basis throughout the United States, was one of the largest of the "large corporations," who, being unable to market new bond issues, "borrowed heavily from banking syndicates." The Bell directors raised in this dangerous fashion $20,000,000, which must be repaid at the end of three years. When the notes on which this $20,000,000 was borrowed, fall due there will be some hard times in Boston, unless the Bell company learns very soon to see the light and to conduct its business on a legitimate basis, instead of along the lines that are being so graphically described by Mr. Lawson in *Everybody's Magazine*, under the title of "Frenzied Finance."

SOUTHWESTERN KANSAS ASSOCIATION HOLDS MEETING

At the recent meeting of the Southwestern Kansas Independent Telephone Association, held at Wichita, some very interesting and encouraging reports were made. Since the last meeting in July three trunk lines were built from Wichita to Newton, Wellington and Winfield. Three more trunk lines are to be built from Wichita to Hutchinson, Blackwell, Oklahoma, and Kingman. These will be all copper and the highest grade of long-distance construction. The line to Newton will be extended to Herrington, giving connections with Kansas City.

This line will be one of the most important to Wichita, as it will give this city direct connection over Independent lines to Topeka, Kansas City, St. Louis and Cincinnati. It will make connections at way points, but eventually a direct line will be built to Kansas City.

The association proposes to put up trunk copper lines between all important points in the State, and the local lines will connect with nearly every village within a radius of 150 miles, and will also be kept up to give good country service.

The trunk line to Oklahoma is to be extended to Oklahoma City, where it will connect with the Independent lines to Texas, giving connection with Dallas, Fort Worth, San Antonio and Galveston.

Rural lines formed an interesting topic for discussion, and reports from the different companies showed that wonderful progress had been made in this direction. All the companies are building country lines for the benefit of farmers, it being stated that over 200 miles of country lines had been built in the vicinity of Wichita in the past three months. The financial reports of the association were extremely gratifying, every company reporting good business and profitable ventures in every department. It was also stated by each company that no financial assistance was needed to carry out its plans and that no foreign money had been invested in any of the enterprises.

The association is composed of 24 of the strongest Independent telephone companies of the State and all were represented. The organization took place last winter, and Wichita was made the permanent headquarters. Four meetings are held here every year. At the first meeting the following officers were elected, who are still serving: C. C. Vandeventer, president; C. Gibson, vice-president; H. D. McVay, secretary; Finlay Ross, treasurer.

NORTHWESTERN INDEPENDENTS TO HOLD A MEETING.

The Independent telephone men of the northwest will hold their annual meeting in Sioux Falls in January. The exact date has not yet been determined upon. The territory covered by these Independent lines is all of South Dakota east of the Missouri River, Southwestern Minnesota and Northwestern Iowa. From seventy-five to 100 delegates are expected to be present.

IN THE OPERATING FIELD.

NEW YORK STATE ASSOCIATION TO REORGANIZE.

AT a meeting of the executive committee of the New York State Independent Telephone Association, held at Rochester, recently, it was decided to amend the constitution and by-laws of the association so that it might become a member of the National Association. The National Association has adopted a constitution and by-laws modelled aftter the general plan of district organization as developed in Ohio. This plan was somewhat different from that which had been followed by the State associations already in existence, and to conform with it they will have to make some changes.

At the New York meeting it was decided to divide the State into twelve districts, and to proceed at once with their organization. This organization will consist of the election of officers for each of the districts, and the choosing of delegate representatives. H. H. Persons was elected trustee of the National Association for New York State.

James B. Hoge, president of the National Association of Independents, was present at the New York meeting. Speaking of it on his return to Cleveland he said: "I am more than pleased with the conditions I found in Independent telephone circles in New York. The whole field seems to be prosperous and flourishing. There is much interest being taken in the work, and the State will soon be fully organized along the lines of the National Association."

A SUCCESSFUL OHIO COMPANY.

ONE of the most successful small telephone companies of Ohio is the Jefferson & Warren Telephone Company, of Orangeville, Ohio. This company was organized in 1896, and now has 875 telephones. The company has just paid its twenty-fifth quarterly dividend. It has an authorized capital of $80,000 and an outstanding capital stock of $73,175. The statement for the year ending October 1 is as follows: Gross earnings, $16,049.41; operating, $9,051.01; net earnings, $6,998.40.

A SUCCESSFUL INDIANA COMPANY.

THE Home Telephone and Telegraph Company is one of the prosperous institutions owned and organized by Fort Wayne people. It began business in 1896, and to-day has 3,200 telephones in service and is each day adding new subscribers.

It has commodious offices in the Home Telephone Building, a handsome three-story structure, owned and built by the company. In addition it owns the stone and brick building at the corner of Calhoun and Masterson streets, where from the south side lines are operated.

The stockholders number nearly 150 people. The long-distance service is done over the lines of the National Telephone and Telegraph Company, which is closely allied to the Home company, although a separate organization, also owned by Fort Wayne capitalists.

The lines of the National Telephone Company thoroughly cover Northern Indiana and reach into Michigan and Ohio. It also owns local exchanges at Kendallville, Auburn, New Haven, Sturgis, Mich., Avilla and other points.

The business of the National Telephone Company has more than doubled in the last two years and new copper toll lines are constantly being built. Both the Home and the National Company have a stock issue of $250,000, on which dividends have been paid regularly for years. The officers are as follows:

Home Company—Directors: Charles S. Bash, president; John P. Reuss, vice-president; Wm. L. Moellering, secretary; Max B. Fisher, treasurer; Isidor Lehman, P. W. Smith, G. Max Hoffman, W. A. Bohn.

National Company—Directors: Henry C. Paul, president; Chas. S. Bash, vice-president; Wm. L. Moellering, secretary; W. A. Bohn, treasurer; Samuel S. Fisher, A. E. C. Becker, G. Max Hoffman, J. M. McKay, E. M. Popp. The management of both companies being in the hands of the secretary, Wm. L. Moellering.

THE CUMBERLAND RAISES RATES.

THE Cumberland Telephone Company has increased its rates to such an extent at Henderson, Tenn., that a movement has been started to organize an Independent company. The service given has been very unsatisfactory and the failure to better this condition at the expense of higher rates has given a great impetus to the organization of a competing company which will be granted a franchise in the near future.

CUYAHOGA'S INCREASED BUSINESS.

THE increase of business of the Cuyahoga Co. for the period between March and October has been beyond expectations. On March 9, at the time when the company's new switch board was placed in service, there were 10,219 Cuyahoga telephones in operation in Cleveland. The figures on Oct. 9 show 12,955. The net increase for this time has been 2,640, or an average of 377 a month. One of the significant things about the report is that the figures for the last of the period show the same rate of increase as those of the first. The last report at hand at the time of writing was for October 11. The figures for that day showed 22 telephones contracted for, or a net increase in the company's income of $613.

This is the largest gain in a similare length of time that the Cuyahoga Co. has ever made. President Dickson attributes it largely to the superior service that is given by the new switchboard.

REPORTED CONSOLIDATION OF PENNSYLVANIA COMPANY WITH UNITED STATES COMPANY.

THE Consolidated Telephone Companies of Pennsylvania, with a system of exchanges extending from McKeesport to Norristown, it is reported, have entered into negotiations for the sale of its properties to the United States Telephone Company, whose plan is to establish a trunk line from New York, via Philadelphia, to Chicago.

Under the plan the United States Company is to come into possession of the Independent exchanges at Norristown, Reading, Allentown, Scranton, Wilkesbarre, Mauch Chunk, Harrisburg, Altoona and McKeesport, all having connection with the Keystone, of Philadelphia.

WASPS' WAR ON TELEPHONES.

IT is reported that the Chinese and Japanese Telephone Company of Shanghai, has its aerial wires, which are enveloped in lead pipes, attacked by wasps which breed in bamboos. In July or August they bore holes in stems to lay their eggs clear of birds. In default of bamboos they have done the like with the lead covering of the cables. The company has coated the lead with boiled linseed oil and canvas, which the insects cannot penetrate.

IN THE MANUFACTURING FIELD

"SUCCESS LIES IN THE KNOWLEDGE OF OUR TOOLS"

A NEW MEASURED SERVICE METER.

A TELEPHONE meter for measured service, by which a patron makes his own record of each time he calls, has just been put on the market by the Measured Service Company, 153, 155, 157 and 159 S. Jefferson street, Chicago, Ill. The meter is designed for either trunk or party lines, and is already being used by several large companies. The meter, a photograph of which is shown in Fig. 2, is operated by the patron, in front of his eyes, and leaves no possibility of dispute by him. The counter, it is claimed, cannot be beaten, a buzzer signal being given to the operator after the meter record has been made.

The particular advantage lies in the fact that statements can be obtained in the central office over the wire at any time desired of the total number of calls used during a given time. Telephone companies can therefore extend their patrons credit, rendering them a statement of the amount due for service rendered, which will correspond with the figures on the dial of the meter. The point urged is that telephone companies can greatly increase their clientage, as well as the total number of calls used, through the facilities offered by this meter for the credit system.

It is asserted that the meter relieves telephone companies of the vast amount of detail work in connection with keeping a record of all accumulated cells. It is read in the auditor's or treasurer's office in printed form, thus eliminating this work from the operators.

A diagram of the circuits of the meter is shown in Fig. 1 for a central energy system. Diagrams for any system may be obtained by applying to the Measured Service Company.

The operation of the meter is as follows: When a connection is made, the calling party pulls the small lever at the front of the small black box, which is 4¾ x 2¾ x 2 inches, and is placed at the substation. This throws a buzz over the wire, notifying the operator that the subscriber has registered. The call is shown on the face of the meter. At the end of a certain period, when it is required to take statements, the record-taker or central office machine is placed in connection with the substation device. The party is called and asked to turn the large crank at the end of the meter. This operation takes a statement on a tape by Morse code at the central office of the number of calls made since the last reading. One portable statement-taker will do the work of the entire exchange. It acts so rapidly that even where the number of calls is as high as ten thousand the record will be transmitted in a few seconds.

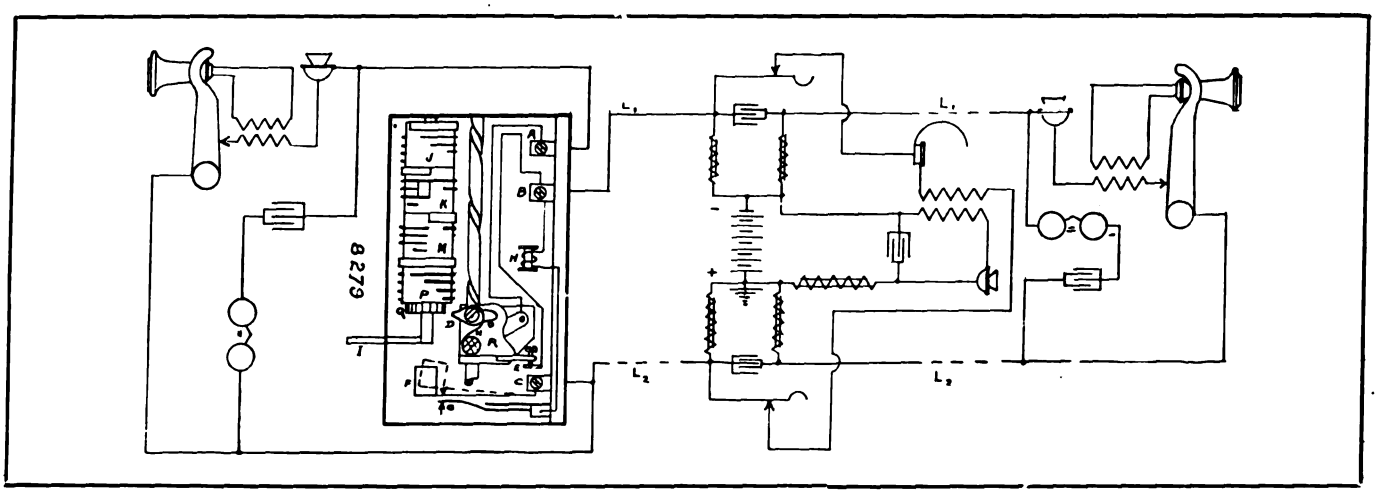

Fig. 1.

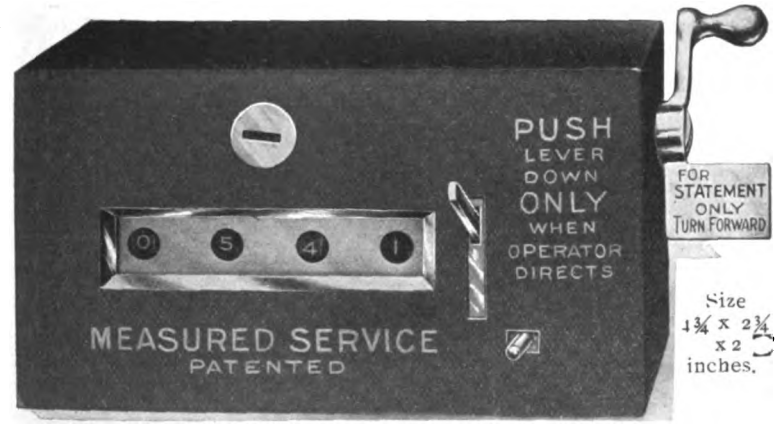

Fig. 2.

The Measured Service Company is covering the United States with demonstrators, showing a working device complete. They will be glad to have a demonstrator call on any telephone company on request, and will also send descriptive literature, circuits, prices, etc.

INSURANCE AGAINST SHOCK.

THE International Telephone Manufacturing Company, of Chicago, it is said, is making its central energy, as well as generator-call, wall and desk telephones, completely eliminating the use of any of the exposed metal parts forming a part of the circuit at any time, thus preventing the user from receiving an electrical shock when using the telephone.

telephone apparatus in view of the many accidents that are constantly occurring from the use of instruments in which circuits are completed through outside metal parts.

One of the most peculiar accidents of this kind recently occurred at Indianapolis, Indiana, as will be seen from the following article from the Chicago *Tribune*, October 29th:

INDIANAPOLIS, IND., Oct. 28.—[Special.]—James Adams of 1624 Cornel avenue is lying in a paralyzed condition at his home as

Digitized by Google

the result of an electric shock received from a telephone he was using in the office of a local coalc ompany.

He was standin gat adesk on which were two telephones, the New and the Central Union telephones. He first used the Central Union telephone, and, not succeeding in getting his number, tried the New telephone.

Adams took the receiver, and, while waiting for his number, rested his chin on the top of the Central Union telephone. A shock resulted that rendered him unconscious.

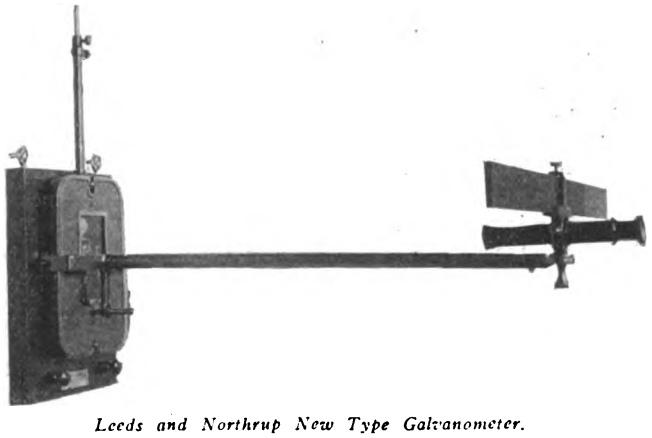
He was soon revived, but, when an attempt was made to move him it was discovered that he was paralyzed from his waist to his feet.

The International Company in designing its apparatus considered these points as one of the most essential in the telephone system, especially for large cities or even rural exchange where there is considerable danger from lightning, and have carried out in every detail the idea of perfectly concealing all working parts of the apparatus and insulating all exposed metal parts throughout their entire system.

NEW GALVANOMETER FOR TELEPHONE TESTING.

THE Leeds & Northrup Co., of Philadelphia, is just placing on the market a high-grade but inexpensive galvonometer of finished workmanship and commendable working qualities that will be interesting to all telephone companies.

The uses of a galvanometer in telephone work are numerous.



Leeds and Northrup New Type Galvanometer.

They usually require a man with considerable experience to handle a high-grade instrument.

The new type of galvanometer is quite complete in itself, being furnished as the illustration shows with a telescope, arm and adjustable scale. This scale with its telescope can be detached from the instrument by simply lifting it off its supports and can be hung upon the wall alongside the instrument when not in use.

The galvanometer may be set up ready for working with the greatest ease. It is only necessary to drive two screws in the wall and hang the galvanometer upon them by means of two eye screws in the back board By simply screwing the eye screws in and out the galvanometer is made to hang vertical when its coil will hang free.

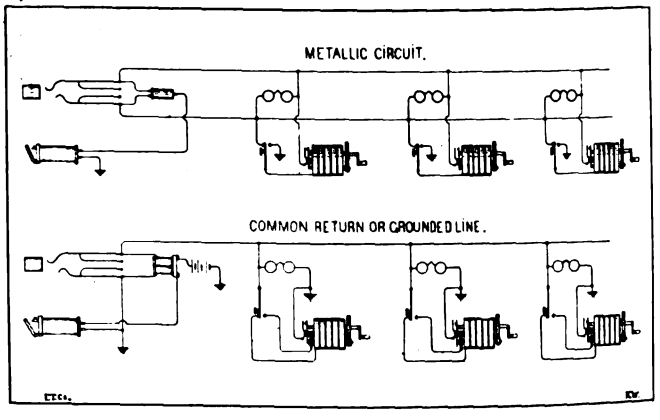
The wide clearance between coil and pole faces make the usually tedious operation of getting the system to swing free, an operation of extreme simplicity, making it possible for an ordinary employee to test out the line with the least delay and little expense to the company.

The galvanometer is of the D'Arsonval type, and is not influenced by magnetic fields. This new instrument is known as the Type P. Defects have all been eliminated, by careful designing and extensive experiments, and the following good features have been evolved. It is of pleasing and graceful appearance, embodying a finish given to expensive scientific instruments. It has a moving system or coil which is always wholly visible. A proportional scale for either steady currents or ballistic workings is furnished.

The coil is magnetically damped, thus giving a quick return to zero with rapid working as a result. Has large, clear scale that is very easy to find and easy to read without fatigue, and a strong suspension that gives no zero shift and which is not easily broken and can be readily replaced. This instrument is being made in quantity by jigs and tools according to a fixed pattern, and is sold at the extremely low price of $20.00. The Leeds & Northrup Company will be glad to furnish further information and complete bulletins to those interested.

RURAL LINE TELEPHONE SYSTEM.

WHERE a number of rural subscribers are connected with central by means of a common line there are several objectionable features in the present practice, among which perhaps, the worst is the necessity of disturbing central every time one of the subscribers calls another. It is customary to have a code of calls by which subscribers on the line can call each other, and it is very annoying to the operator to have her attention called to the line whenever one subscriber calls another, and especially where there are several such lines entering the switchboard and going to the position of one operator. In addition to her regular work in answering her subscribers on single lines, the operator must always be on the alert for a signal for central on these rural lines, which is usually indicated by the buzzing of one of the line drops or by the ringing of an extension bell. In the ordinary method the operator answers innumerable times only to find that she was not wanted.



Ericsson Rural Electric Signalling System.

The Ericsson Telephone Company, 296 Broadway, N. Y. City, has recently placed on the market devices for metallic circuit, common return or grounded rural lines, which entirely overcome these annoyances at the switchboard in the operation of such lines. By means of these devices, the subscribers can call each other without calling central or without central knowing that one subscriber has called another or that they are conversing together. Also the subscriber can call central without calling any other subscriber or disturbing any one else. By this means the operator is relieved of the constant attention necessary on the rural lines,

FOR SALE

Advertisements under this head, $1.00 for 25 words or less for each insertion. Prepaid.

FOR SALE—Independent magneto plant in Southern town, 3,500 population; 200 drop switchboard; 150 drops in operation; gross annual income $3,500; fixed expense $1,300; in operation five years; no competition; town and plant growing fast; price, $10,000. Address Box 255, care AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 255

FOR SALE.—I have a telephone proposition which will interest any one of means who cares to investigate. This property is in fine condition; located in excellent field and paying. Write me at once. Box 270, care of AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 270

FOR SALE.—Telephone Exchange in town of 850. Equipped with Stromberg board; North Telephones; 65 local subscribers; 15 party lines; good connections. Further particulars given on request. Address Everton Telephone Co., Everton, Mo. 271

WANTED

Advertisements under this head, 25 cents for 25 words or less for each insertion. Prepaid.

WANTED—A first-class business man with administrative capacity to act as general manager of a telephone company operating upwards of 10,000 telephones. One having practical telephone experience, including the operation of toll lines, preferred. State age, experience, and give references. Address Box 266, care AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 266

WANTED—Position by expert switchboard man, good wire chief and all-round telephone man, capable of improving your service. Address Box 256, care of AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 256

WANTED—Position; nine years in the business; married; sober; can get and hold business; at present assistant manager with company having 14 exchanges, about 400 miles of toll line. Would accept position as manager with appreciative company having undeveloped territory which by proper handling and untiring effort could be built up. Address Box 267, AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 267

WANTED.—Manager of exchange of 300 common battery and magneto telephones, located in New York State. Good salary at start, and steady increase to right man. Only hustlers who want and can earn good pay need apply. Address Box 259, care THE AMERICAN TELEPHONE JOURNAL, N. Y. 259

AM open, any time between now and March 1, for position as superintendent or manager of exchange. Am, at present, managing a system built by me, but want larger field. Fifteen years' experience in all branches of telephone business. Would accept good position other than above mentioned. Best of references furnished. Address Box 268, AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 268

WANTED—Position as manager or superintendent of Independent exchange. Am temperate, married, and have had four years' practical experience. Address Box 273, AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 273

WANTED.—I am seeking a gilt-edged investment in some first-class telephone property. Not particular as to location, but must be shown before I buy. Address, Box 269, care of AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 269

which is otherwise required to distinguish the call for central from other rings. In the Ericsson system when central is wanted the drop indicates it just as on an individual line, and this is accomplished without grounding one side of the metallic circuit, as is usually done in other systems, thereby making the line unbal-

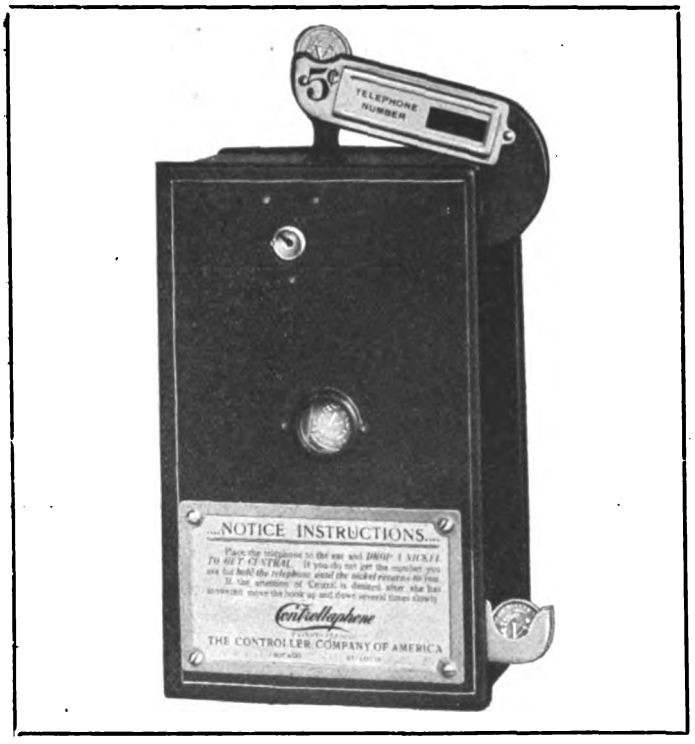

Fig. 2. Stroud Controller.

anced and noisy. With the Ericsson devices the line remains perfectly balanced in relation to ground under all circumstance and all the subscriber has to do to call central is to press a button or strap key. When the subscriber calls other subscribers the calling is done in the usual manner with the individual signals and central is not disturbed. Precisely the same results are accomplished on common return and grounded lines, and the system is so simple and saves so much annoyance to the operator, that every exchange having such rural lines entering their switchboard should know about this system, and consider adopting it.

We suggest to our readers to correspond with the Ericsson Telephone Company, No. 296 Broadway, New York City, regarding the system.

THE BAIRD MANUFACTURING COMPANY has received a letter during the past week from a prominent telephone company from which the following is a quotation: "Will you please send us your latest catalogue of pay-station boxes, and most particularly as to the single 5c. box. We have bought quite a number of this type of box from the ——— company, but are frank to admit that we do not like them quite as well as your boxes."

NEW TYPES OF "CONTROLLERS."

"A MACHINE that won't let the telephone talk until you put in a nickle." This is the definition of the latest type of telephone coin devices made by the Controller Company of America, given by an Iowa telephone man. While it is not so short as "Controller" or "Controllaphone," the names bestowed by the Controller Company on its apparatus, the Iowa gentleman's definition is certainly descriptive and to the point.

The Controller's Company's newest type of "Controllaphone" is pictured in Fig. 1, and is known to the trade as No. 6. They call this the "Educational Set" for reasons which are given in their new bulletin No. 6, just issued. This bulletin will be sent to any telephone company or officer thereof for the asking, and should be had by every company operating on a measured service basis, or contemplating such a departure from flat rate service.

The "Educational Set" is a combination of wall telephone set, and slot machine, being designed to meet the demand for a compact coin service set. It consists of the Stroud Controller mounted on a pressed steel backboard. The extreme dimensions of the set are 5½ inches by 11 inches. A well-made self-contained hook switch is fastened to the base, extending out so as to hold the receiver in the ordinary manner. Just below the "Controller," on an extension of the base an adjustable transmitter arm is mounted. Any standard make of receiver and transmitter may be attached to this set.

No part of the containing case or base forms any part of the circuit, and there are no binding posts or terminals exposed.

The Stroud Controller shown in Fig. 2 is the center focus of the Controller Company's apparatus. It is known as No. 1, and is used by many of the largest Independent companies. The main principle of this controller is that the central operator can-

Fig. 1. Controller Co.'s Educational Set.

not be signaled until a nickel or a token in case service is less than five cents is deposited in the top slot as shown in the illustration. The act of dropping a nickle in this slot, with the receiver off the hook, signals the operator. in case the party wanted is busy or does not answer, the operator causes the nickle to be

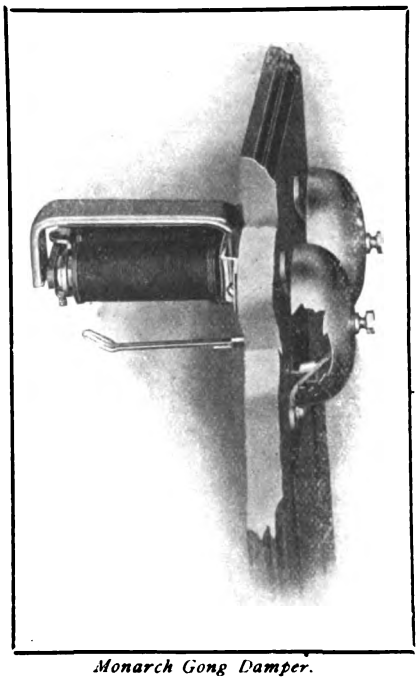
returned to the party calling. A nickle is thus shown in the bottom slot. The operator's time is not taken up by her having to ask the party to drop in the nickle, nor does she have to wait while the party makes change. The subscriber has to do all this before he gets the operator. The Controller Company, with general offices at 1060 Monadnock Block, Chicago, will be glad to mail their series of instructive bulletins to any one sending a request.

THE MONARCH GONG DAMPER.

THE Monarch Telephone Manufacturing Company has recently added a new feature to its compact telephone, which will be appreciated by both exchange men and subscribers. Almost every one using this common type of telephones has experienced the annoyance caused by the continued vibration of the ringer gongs after the receiver has been placed to the ear. The sensitive transmitters manufactured to-day take up the vibrations and magnify the mto such an extent that conversation is impossible until the noise is stopped. It is usually the custom to place the hand on the gongs to deaden the tone, but the device of the Monarch Company make this unnecessary.

The accompanying cut shows the means of stopping the vibrations. As will be seen, a lever is fastened by hinges on the door of the telephone just below the ringer. When the door is closed, this lever rests upon the switch hood so that the raising of the hook also raises the lever. Two prongs or forks of the lever extend through the door, one into the inside of each gong, and are equipped with leather discs on their ends. These discs are normally held away from the gongs, but the tilting of the lever by the removal of the receiver throws them down into contact with the metal and effectually stops further vibrations.



Monarch Gong Damper.

A patent has been granted to the Monarch Company on this device, and they are installing it in all of their compact telephones. No extra charge is made, notwithstanding the advantages derived, as it is the policy of this company to make their telephones as efficient and up-to-date as it is possible to produce them. A more complete description of this gong damper will be found in a bulletin now being prepared.

A NEW CROSS-ARM COMBINATION.

MR. J. S. BOGGS, of Albany, Ga., the well-known manufacturer of Georgia Yellow Pine Cross-Arms, has effected a working combination with the Waymer-Moore Company, of Jacksonville, Fla. The latter company are also well-known cross-arm manufacturers. Under the new agreement Mr. Boggs will act as sales agent for the Waymer-Moore Company. This makes a very strong combination, and insures that all customers will receive prompt shipments as well as lowest possible price and the best cross-arms. An enormous tock will always be on hand. The motto of the new combination will be to do everything possible to please customers. We would call aur readers attention to Mr. Bogg's announcement in the advertising pages of this section, and also advise them to communicate with him when in the market for arms.

WILL HANDLE TELEPHONE SECURRITIES.

AT last the Independent telephone field is to have a reliable and influential medium for marketing its securities, and for negotiating its various financial deals.

At Chicago during the morth of October a new concern was organized under the name of the Independent Telephone Syndicate, which will afford facilities hitherto lacking, for the promotion and financing of all legitimate propositions in this field. Undoubtedly, the new organization should prove of great benefit in the Independent field where many unusual opportunities for investment exist.

The Independent Telephone Syndicate will list and market telephone securities, buy and sell telephone properties, and effect transfers of mutual benefit to the parties interested.

One of the most serious handicaps of the Independent field thus far has been the fact that it has lacked proper facilities for buying, selling, building and promoting. The field, already large and lucrative,, has demonstrated that still further steady increase may be expected of it, and that it will prove of a permanent character. With this kind of a field, and with the advantages which the new firm will enjoy in the way of experience, means and influence, it should not only prove of great service to its patrons, but be successful from the start.

In this organization are found some of Chicago's leading business men, who enjoy both capital and wide experience in telephone and financial aflairs.

Offices have been opened on the seventh floor of the Great Northern Building, No. 708, in the heart of Chicago's business district, where all callers and inquiries will be courteously received by Mr. J. H. Duryee, who was for eighteen years connected with the Prairie State Bank of Chicago.

THE CENTURY TELEPHONE CONSTRUCTION CO., of Buffalo, N. Y., is building a new switchboard for the Lowville, N. Y., exchange of the Black River Telephone Company. It has been completed five common battery equipments for exchanges of the Livingston County Telephone Company, Livingston, N. Y., and also a common battery equipment for the Holley Telephone Company, Holley, N. Y.

THE L. B. ALLEN COMPANY, INC., of Chicago, maker of the Allen Soldering stick, is sending to the trade several mailing cards, folders and booklets, giving interesting facts concerning its prduct. In one of these the company soys:

"We've made a stick for you and we will give it to you if you ask for it. We wantyouto use it, test it, compare it, judge it, see what it does, and what it doesn't. The Allen is the stick that sticks, gives a firm, flush joint in a jiffy."

With each sample of solder the company mails a neat folding foot rule.

THE CENTURY TELEPHONE CONSTRUCTION CO., Buffalo, N. Y., has received orders for two magneto switchboards from the Citizens Telephone Company, Watertown, N. Y.

TELEPHONE PATENTS

AN IMPROVED HOOKSWITCH FOR TELEPHONE DESK SETS.

K. Weman, New York, N. Y., patents (No. 771,343) an improved hookswitch for telephone desk sets. The essential features of this invention are shown in the illustration (Figs. 1 and 2), from which it appears that the inventor provides a very compact set of springs *T S M L P*, which are contained in the top of

Fig. 1.

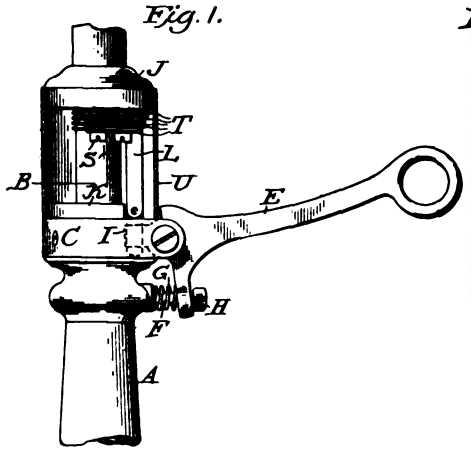

Fig. 2.

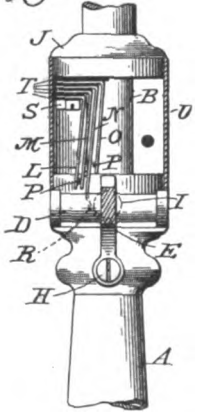

the transmitter stand and covered by means of the casing *U*, which is easily removal to permit of inspection and repair. The springs are operated by means of the lever hook *E*, which is pivoted at *G*.

AN IMPROVED MICROPHONIC CAPSULE.

E. B. Fahnestock, New York, patents (No. 771,135) an improved microphonic capsule. The object of this invention is to provide an improved method of constructing and using microphones in telephone transmitters. The general appearance of this invention is shown in the accompanying illustration. The inventor provides a block 5 which may be of metal or other convenient of the microphone, as is shown in the section. There are two

Fig. 1

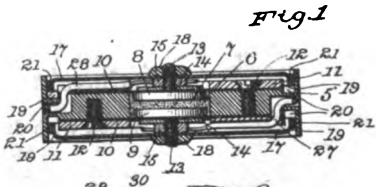

Fig. 2

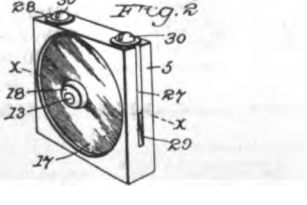
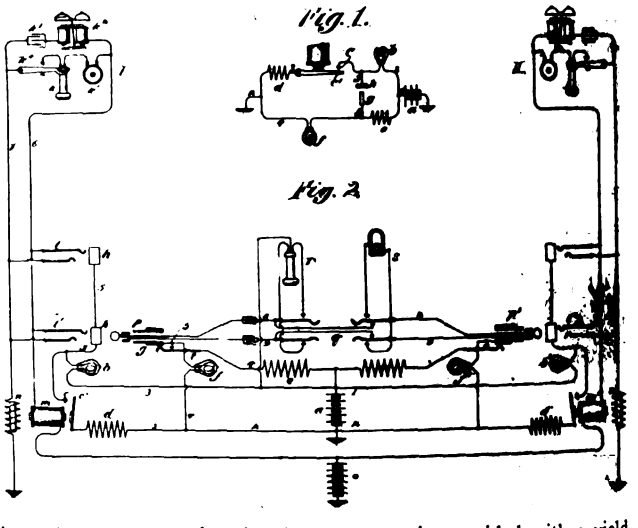


substance. This block is recessed to contain the working parts electrodes *13*, which are secured to diaphragms *17* by means of the nuts *81*, from which it will be seen that this invention belongs to the double diaphragm order. The granular carbon *7* is contained between the electrodes *13*. The essence of the invention consists in the fact that the block containing the microphone is hollowed out, as shown at *19*, so that the diaphragms touch nothing but the studs of the electrodes. The edges of the diaphragms are dished, as shown at *19*, and after being secured in place upon the studs *13* a little rubber cement is poured around the circumference of each one, thus holding the diaphragm in place by means of a flexible material.

MEASURED SERVICE SYSTEM.

F. R. McBerty, of Evanston, Ill., and J. L. McQuarrie, of South Orange, N. J., patent (No. 771,996) an improved measured service system and assigned to the Western Electric Company. This invention relates to measured service systems in which the recording apparatus is located at the substation, and so arranged that in case the subscriber does not obtain his connection, he is enabled to rebate the charge. The circuit employed is shown in Fig. 1, and a general view of the apparatus in Fig. 2. From Fig. 2 it is seen that the meter consists of a metallic box carrying a set of dials which record the number of calls and and indicator which shows whether the message is charged or not, and a crank whereby under certain conditions the subscriber is enabled to rebate the call. This invention is best understood from a description of its operation. Fig. 1 represents the circuit of a four party line in which *S1*, *S2*, *S3* and *S4* are respective apparatus. *S3* is shown in detail, the other substations diagrammatically, but it is understood that each substation is supplied with the same apparatus as shown for *S3*. The exchange is called in the usual manner by removing the receiver from the hook. If the line is busy at some other station, the test relay *L* is excited, disconnects the branch 5 containing the service meter, and therefore the subscriber is not charged with the call. If the line is free, the circuit 765 is completed, the magnet *m* of the service meter is excited by current from battery *b*. This magnet is a peculiar one, known as a

Fig. 1.



two-step magnet; that is, the armature is provided with a yielding spring that actuates the stop *u*. When battery is connected to the line, a certain current flows, exciting the magnet to pull the armature up one step. The key *f* is provided with a generator *g* giving a higher potential, say 110 volts. When the operator touches the key, this additional pressure excites the magnet *M* and causes its armature to make the second stop. The first step of the armature releases the charge-shutter *p*, which drops and indicates that the meter has provisionally registered the charge. The shutter closes the contacts *q q'* and the armature the contacts *z z'*, whereby the circuit *10* from lever *y* to earth through magnet *m* is completed through both the parallel branches and a locking circuit for the magnet through path *10* independently of the telephone switch. If the central office does not answer, the subscriber may restore the normal condition of the apparatus by pulling the rebate lever *w*. This lifts the shutter *p*, opening the contacts *q* and *q'* and operates the transmitter switch *y*, shifting the connection of the branch containing the magnet to conductor *2*, which is normally open. The locking circuit of the magnet being broken, its armature falls back, opening contacts *z z'*, allowing the shutter to be latched by detent *r*. If the operator responds by plugging into the spring jack, the battery *b* is reversed and the subscriber is prevented from rebating the charge as long as the connection is up at the central office. If the operator finds that connection cannot be given, she will tell the calling subscriber to hang up his receiver and work the rebate lever.

THE WEEK'S MESSAGES

FINANCIAL.

ANDERSON, IND.—The Delaware & Madison County Telephone Company has declared a six months' dividend of 1½ per cent.

MOUNT ZION, IND.—The Mount Zion Telephone Company has increased its capital stock from $8,000 to $20,000.

FRANCHISES.

AMHERSTBURG, CANADA.—The town council has granted the Ontario Independent Telephone Company a franchise. The company will immediately begin the construction of a plant in this town.

MATTOON, ILL.—The Mattoon Telephone Company has asked the city council for an extension of its franchise.

MAYSVILLE, KY.—The Maysville Telephone Company has purchased a franchise sold at auction October 22d for a period of 20 years to construct and operate telephone lines along all public roads, turnpikes and under navigable waters in Mason County, Ky.

ERICK, OKLA.—L. M. Brooks has been granted a franchise to put in a telephone system here.

CAMERON, W. VA.—The Carmel Telephone Company has applied for a franchise in this town.

ELECTIONS.

JACKSONVILLE, ILL.—At the annual meeting of the directors of the Illinois Telephone Company, the following officers were elected: E. P. Kirby, president; A. L. French, vice-president; E. S. Greenleaf, treasurer; R. A. Gates, secretary-auditor; C. F. Tonn, general manager.

NEW LONDON, IA.—The stockholders of the Henry County Telephone Company have elected directors as follows: J. L. Portlock, Green Lee, T. T. Laughlin, W. J. Franey, Frank Smith, J. E. Peterson, J. T. Whiting.

CARTHAGE, MO.—The stockholders of the Home Telephone Company at their annual meeting elected the following directors: W. H. Warren, John Scovern, Theodore Gary, H. E. Scovern and John W. Layne.

BUFFALO, N. Y.—At the recent annual meeting of the Frontier Telephone company the following officers were elected: H. H. Persons, president; E. C. Lufkins, first vice-president; E. S. Wayland, of Scranton, second vice-president; S. L. Mesmer, treasurer, and John Jolly, secretary.

COMBINATIONS.

HUNSTVILLE, ALA.—The principal stockholders of the Girley and New Hope Telephone Company have purchased the property of the Huntsville, Guntersville and Gadsden Telephone Company and will merge the two systems.

LITTLE FALLS, N. Y.—Irving H. Griswold, representing the Home Telephone Company of Albany, Troy, Schenectady and Cohoes has purchased controlling interest in the Interstate Telephone Company of this city.

NORRISTOWN, PA.—The Consolidated Telephone Company has entered into negotiations for the sale of its plant to the United States Telephone Company.

NEW COMPANY NOTES.

WASHINGTON, D. C.—Articles of incorporation have been filed with the county clerk for the State Mutual Telephone Company with a capital stock of $50,000. The incorporators are A. D. Weller, T. J. Gray, T. B. Lee, Frank R. Hollingshead, E. M. Route, J. Dan Blackistone, and A. J. Bette.

COCOA, FLA.—The Brevard Telephone Company has been incorporated with a capital stock of $5,000 by H. S. Williams, J. Paxton, H. S. Hardee, L. S. Jones and R. N. Andrews.

KEITHSBURG, ILL.—An Independent telephone company is being organized here, particularly to secure connection with outlined communities and other Mercer County towns.

INDIANAPOLIS, IND.—The National Telephone & Telegraph Company of Wheeling, West Virginia, has been incorporated under the laws of the State of Indiana with a capital stock of $250,000, $175,000 of which is invested in Indiana. The president is H. C. Paul.

PETERSON, IOWA.—The Spring Brook Rural Telephone Company with post office address at Peterson has been incorporated with a capital stock of $1,000. The board of directors are: C. H. Felton, George L. Keene, Albert Clark, Charles Mohrer, William C. Mueller, Fred Roggow and Henry Miller. The officers are: Henry Miller, president; Theodore Roths, vice-president; Fred Roggow, secretary, and Henry Stier, treasurer.

SUTHERLAND, IOWA.—The Gaza and Sutherland Telephone Company has been incorporated with a capital stock of $600. The board of directors are: J. J. Short, H. E. Kaiser, B. F. Miller and Frank Tierney and Frank Dabric.

WAVERLY, IOWA.—J. W. Bang and C. H. Barrows have organized two rural telephone companies, one the La Fayette Rural Telephone Line, of which J. B. Baker is president, and J. W. Wilkin secretary and treasurer. The other the Washington Rural Telephone Line, F. C. Meyer president, and S. M. Lehman, secretary and treasurer.

ELLSWORTH, KAS.—The Lyons Telephone Company has been incorporated with a capital of $12,000 to give telephone service to the town of Lyons, Kan. C. F. Pohlman, Ellsworth, president; W. D. Jellison, Wilson, vice-president; M. L. Meek, Ellsworth, secretary; G. T. Tremble, Ellsworth, treasurer, and H. N. Williams, manager, Lyons, Kansas.

PEKIN, KAS.—The Pekin Telephone Company has been incorporated with a capital of $4,500.

EASTBROOK, ME.—The Eastbrook Telephone Company has been incorporated with a capital stock of $2,000. President, S. S. DeBeck, of Franklin; treasurer, R. B. Lawrie, of Eastbrook.

MANCHESTER, MASS.—The Woodland Telephone Company has been incorporated with a capital stock of $10,000 by H. E. Emery, J. T. Collins, of Manchester, and F. S. Collins, of West Gardiner.

DETROIT, MICH.—Charles E. Chaney, James A. Forrestor and Chas. W. Taylor, of Detroit, have incorporated the Shore Line Telephone Company with a capital stock of $50,000.

NEWTON, MICH.—The Newton & Leroy Telephone Company has been organized to build farmers' lines in the two above-named townships. The principal stockholders of the company are E. C. Corey, J. A. Hurd, Henry Randt, H. W. Flanders, C. D. Spooner.

SWEET SPINGS, MO.—The Sweet Springs Telephone Company has been incorporated with a capital stock of $20,000 by B. H. Dickson, R. S. Hays, C. K. Smith and others.

MEDFORD, OKLA.—The Medford Telephone Company has been incorporated with a capital stock of $3,000 by D. L. Cline, J. Sharp and W. S. Long, all of Medford.

WILLAMETTE, ORE.—The West Oregon Telephone Company of Willamette has been incorporated with a capital stock of $2,000 by Charles Baker, G. P. Gros and E. S. Kruse.

LUMBER CITY, PA.—The Lumber City Rural Telephone Company has been organized with the following officers: C. S. Kirk, president; Dorsey Hill, secretary, and Dr. H. Woodside, treasurer. Executive committee: D. H. Watts, J. M. Krebs and Harrison Straw.

PERRYSVILLE, PA.—The Perrysville Telephone Company has been organized for the purpose of operating a telephone line between Genesee, New York and West Bingham, Pa.

UNIONTOWN, PA.—The Bruceton & Fairchance Telephone Company has been incorporated with a capital stock of $100,000. The officers are: J. H. Walls, of Brockville, West Virginia, president, and George B. Irvin, of Fairchance, vice-president.

STORLA, S. D.—A telephone company has been organized by farmers residing in this vicinity. Four lines will be constructed with the central office located here.

PERSONAL.

FRANK CRIPPEN has been appointed manager of the Mutual Telephone Company's system at Alpena, Mich.

H. NELTHORPE has been appointed wire chief for the Wisconsin Telephone Company at Kenosha.

A. JACOBI has been appointed county manager of the Sunset Co.'s system in Alameda County, Cal.

ALEX. WILLIAMS has been appointed general manager of the Minnesota Central Telephone Company.

J. A. WRIGHT has taken charge of the mechanical department of the Home Telephone Company at Thornton.

MISCELLANEOUS.

LOS ANGELES, CAL.—A. B. Benton is preparing plans for the telephone exchange of the Home Telephone Company at Redlands. The building will be 40 x 100 and thoroughly fire-proof.

QUINCY, ILL.—Samuel G. McMeen, of the firm of McMeen and Miller, consulting engineers, of Chicago, has opened an office here to look after the engineering work of the new Independent telephone system.

CHANDLER, IND.—The Chandler Telephone Company, which was recently incorporated with a capital stock of $2,500, will build a local exchange and operate telephone lines throughout the country. The chief organizers of the company are: W. M. Gardiner, W. M. Cosler and J. W. Webb.

DES MOINES, IA.—J. Sebastian, of the Rock Island Railroad, is endeavoring to have a telephone factory moved to this city.

GRAND RAPIDS, MICH.—Alexander W. Macrae, warden of the city and county of St. Johns, New Brunswick, visited this city to inspect the plant of the Citizens' Telephone Company with a view to securing data to present to the home municipality, as a movement is on foot in St. Johns to install a municipal telephone plant.

HUTCHINSON, MINN.—The Hutchinson Telephone Exchange Co. has distributed a new directory which contains the names of 294 local subscribers, 111 subscribers on farmer rural lines, and nine toll stations

owned by the company outside this city. The company has had a new commissariat wagon built to take the place of the one destroyed by a cyclone in August.

MANKATO, MINN.—The Minnesota Valley Telephone Company has made connections with Worthington and Windom, giving connection with Sioux Falls, Heron Lake, Brewster and other points via the Minnesota Valley.

JEFFERSON CITY, MO.—The case of the State against the Missouri & Kansas Telephone Co., to compel a reduction of the telephone charges, on the Bell system in Kansas City, has been postponed to the April term of the Supreme Court.

GENEVA, NEB.—In the recent fire in this city the central office of the Fillmore County Telephone Co. was badly damaged.

HATTON, N. D.—A fire disabled the telephone exchange.

PHILADELPHIA, PA.—The annual report of the secretary of internal affairs regarding telephone companies incorporated in the State of Pennsylvania for 1903 shows 87 companies, of which 78 are Independent concerns and nine Bell organizations. The total number of Independent telephones in use by 72 companies is 62,077, the investment being $19,839,045 or an average investment of $320 per telephone.

WAYNESBORO, PA.—The Pennsylvania Telephone Company has submitted a proposition to lease its system in the city to Waynesboro capitalists.

FORT WORTH, TEXAS.—A plan is now on foot to consolidate the Independent telephone exchanges of Brownwood, Ballinger, San Angelo, Paint Rock, Eden, Menardville, Coleman and possibly Abilene, Sweet Water and Colorado. The matter has not yet crystallized into definite shape.

SAN AUGUSTINE, TEX.—The Sabine Valley Telephone Company will soon move into its new building. A new switchboard is being installed.

UNDERGROUND.

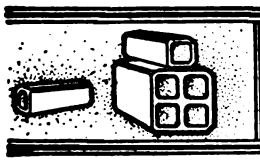
LOS ANGELES, CAL.—The city council is making arrangements to have the underground telephone and telegraph wire district enlarged and to see that all of the companies put the wires underground in that district.

WATERBURY, CONN.—The Southern New England Telephone Company (Bell) will shortly begin the work of constructing 30,000 feet of underground conduits in Waterbury.

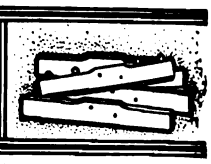
AURORA, ILL.—The Northern Illinois Telephone Company is laying a number of its cables underground.

LA PORTE, IND.—The La Porte Home Telephone Company intends to place all of its wires in the down-town districts underground and in time to extend the same to the residence districts. The company expects to put 10,000 feet underground this fall.

CHESTER, PA.—The telephone and telegraph wires in this city will be placed underground.



New Construction in the Field



NORTH BIRMINGHAM, ALA.—The new telephone system of the People's Home Telephone Company has been completed and all the telephones installed.

MILLIDGEVILLE, GA.—The Central Georgia Telephone Company has completed a long distance line to Eatonton.

STERLING, ILL.—The Interstate Telephone Company is building a line from this city to Rock Island.

WEST BURLINGTON, IA.—The Burlington Rural Telephone Company is adding a large number of new subscribers to its system in this vicinity.

HARRIS, KAN.—The Harris Telephone Company is building several additional miles of rural lines, besides a toll line to Amiot.

OTTAWA, KAN.—A toll line is being built to connect this town with Kansas City.

PLYMOUTH, KAN.—The Plymouth Farmers Telephone Company is building a line to Magda.

RISING SUN, MD.—The work has commenced on the Cecil Farmers Telephone Company.

SOUTH ASHFIELD, MASS.—The Heath Telephone line is to be extended to this village.

CADILLAC, MICH.—The Citizens' Telephone Company has decided to extend its lines to Meauwataka, Boon and Henrietta. Construction work will be started shortly and it is expected that the system will be in operation in three villages before the first of next year. A large number of farmers' lines will be installed.

ALBERT LEA, MINN.—The Alden Telephone Company is making a number of extensions to its system in this vicinity.

ANOKA, MINN.—The Northwestern Telephone Exchange Company is installing a cable system.

BELGRADE, MINN.—Work on the Game Lake Telephone line will be begun this week.

BYGLAND, MINN.—A telephone line is being built through here.

IVANHOE, MINN.—The Lincoln County Telephone Company has completed its line from Hendricks to Ivanhoe and work is now commenced on the Ivanhoe exchange.

LERDAL, MINN.—The Lerdal Telephone Company's line is being put up with great rapidity.

MANKATO, MINN.—The Minnesota Valley Telephone Company is making a number of extensions to its system.

STANCHFIELD, MINN.—The Northwestern Telephone Company is putting a new line in from Stanchfield to Maple Ridge, via Elm Park.

WATSON, MINN.—The Citizens Telephone Company is putting in new telephones in some of the business places. It is the intention of the company to extend so as to make a regular telephone system of it.

BOSTWICK, NEB.—The Red Line Telephone Company is putting telephones in in this vicinity.

HUMBOLDT, NEB.—The local telephone company has installed a new aerial cable to take care of its increased business.

EGG HARBOR, N. J.—Ten miles of telephone line will be built from Egg Harbor to Green Bank.

WINDSOR, N. J.—The Farmers and Traders Telephone Company will construct telephone lines in this vicinity.

GAINESVILLE, N. Y.—The new telephone system, which will connect this place with the village of Castile and Silver Springs, is nearing completion. The exchange will start work with about 125 subscribers and represents a total investment of about $15,000. The principal organizers of the company are H. A. Pierce, M. N. Cole, A. B. Windsor.

NEW LISBON, N. Y.—The New Lisbon Farmers Telephone Company is extending its system and will install about 20 new telephones.

PROSPECT, N. Y.—The West Canada line is being extended to Remsen.

UNION, N. Y.—The Main & Union Telephone Exchange has arranged for the construction of a local exchange. It has also arranged for the extension of lines to Vestal and Endicott in the near future.

BIRDSBORO, PA.—The Conestoga Mutual Telephone Company, which was organized among the farmers of Conestoga Valley and this vicinity about a year ago, is branching out and extending its lines into competitive territory. It has connections with Birdsboro, and has a toll agreement with the Independent Company. At present it is extending the line to Pottstown and Reading.

Butler, Pa.—F. Neal, of Kittanning, is securing rights of way for the Butler & Coylesville and Kittanning telephone line, which is to be built to Butler via Coylesville, and will be a feeder of a new line into Pittsburg.

CONNELLSVILLE, PA.—The Tri-State Telephone Company has opened connection with the Pittsburg & Johnstown Long Distance Telephone Company, giving service with Greensburg. The local company has completed its Flatwoods line and work is progressing on the line from Union to Cheat Haven, connecting with the Point Marion Company and giving a direct circuit to Morganstown. The new line to Waltersburg, Smock and Keister will be put in operation shortly.

ECONOMY, PA.—The Economy Telephone Company will install lines in Berlin and Somerset.

FALLS CREEK, PA.—The Elk Telephone Company is building a line to this city to connect with the Summerville system.

READING, PA.—Work on the Consolidated Telephone Company's trunk line has been completed as far as Womelsdorf and it is expected that communication with Lebanon and the west will be effected by the beginning of next week.

HIGHMORE, S. D.—W. N. Curtis, of Milton, Iowa, has been engaged by the Hyde County Telephone Company to install their new exchange.

IONA, S. D.—A line is being constructed from Bonesteel to the new town of Gregory giving connections with this town.

ALVIA, TEX.—The Alvia & Angleton Telephone Company is arranging to extend its lines to Friendswood. This will add about 15 new telephones to the present system.

CALDWELL, TEX.—Work has commenced on the extension of the telephone line from Cooks Point to Rita in the extreme northern part of the county. This gives Caldwell connection with every section of the county.

FALFURRIAS, TEX.—Telephone service will be established between Alice and Falfurrias and probably the larger ranches in the surrounding country as soon as possible.

BELLAIRE, W. VA.—The Bellaire Telephone Company is contemplating a number of extensions which it will put through in the near future.

ONO, WIS.—Work on the Farmers' Telephone line between here and Maiden Rock is being pushed right along.

BOOK NOTICE.

SELF-PROPELLED VEHICLES. A practical treatise with illustrations, by J. E. Homans, A. M., 8vo, pp. 672, bound in black vellum, gilt top, gold titles. Theo. Audel & Co., New York. Price, $2.00. This book can be purchased through the AMERICAN TELEPHONE JOURNAL.

In presenting the new edition of this work, the publishers announce that the book has been thoroughly revised, and in large part rewritten.

The general principles of automobile construction and operation, including steering devices, underframes, wheels, tires, bearings, lubricators, are included in the opening chapters. Then follows an exhaustive account of the theory, construction and operation of gas engines, occupying over 100 pages. Several typical engines are taken up and discussed separately, and their properties, as regards balance, speed and power, are discussed in the light of fundamental principles. The explanations of the governing devices are clear and valuable, while the discussion of ignition, including the hot-tube, and the primary and secondary sparks, cannot fail to prove of the utmost value.

To those companies which contemplate the use of automobiles in the inspection, repair and construction of their lines we would suggest this work as offering a guide to the selection and operation of this style of vehicle.

Bituminized Fiber Conduit
For Underground Construction

Combines the **good features** of other conduits. **Eliminates** the **bad features** existing in many kinds. **Has valuable features** not found in any other ducts. :: ::
Made in 7-foot lengths with male and female joints, making construction very rapid and simple, with consequent low cost. :: :: ::
Alignment is perfect and permanent without tedious care and skill required in laying of butt-joint conduits. Users are astonished by the ease and rapidity with which cables can be drawn in, and this without the slightest scratching or injury to the lead covering thereof. Made in sizes from 1-inch to 10-inch diameter. ::
Bends of any radius and any angle. :: ::
Write us for further information and prices, stating sizes and quantities required. :: :: ::

THE AMERICAN TELEPHONE JOURNAL

Our New Department "In The Manufacturing Field"

In the last issue of the JOURNAL this department was added. We believe our readers are interested in new telephonic devices. It is our endeavor to keep matter appearing in this department to the same standard that characterizes our regular reading pages.

As we expected, the department has met with a cordial reception on the part of our readers, one of whom writes:

"The new departure in your issue of November 5th, 'In the Manufacturing Field,' cannot help being valuable, as it will enable readers to see what new things are being brought out. *No one can stay in the business unless he keeps up with its advances.* The man who keeps posted as to the different styles and kinds of apparatus can always tell where to get the supplies to fill any needs; if he will only write for prices, he will save money. This I know from experience.

"C. L. HOWK, Manager,
"Local Telephone Co., Norwalk, Ohio."

This letter is one of many that have already been received. We would like to have the views of all our readers on this new department.

PAUL LATZKE, President WILLIAM H. McDONOUGH, Editor

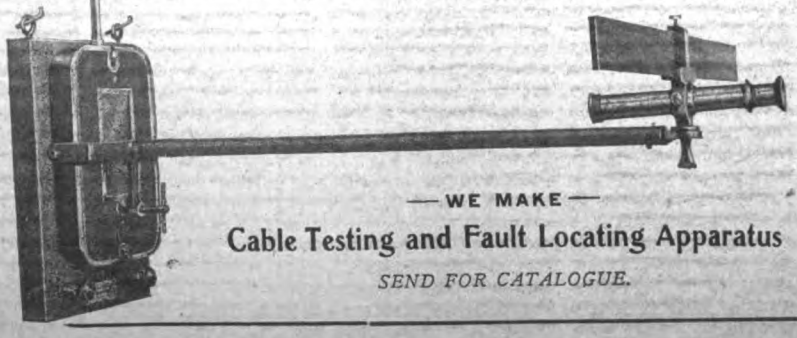
ELECTRICAL MEASURING INSTRUMENTS
D'ARSONVAL GALVANOMETER TYPE P.



—WE MAKE—
Cable Testing and Fault Locating Apparatus
SEND FOR CATALOGUE.

Stimulated by the large demand for a good Galvanometer at a reasonable price, we have gotten out this instrument. It is well made, of finished workmanship, pleasing appearance and excellent working qualities. Its low price is due to good design, careful manufacture and production in quantity, and in no detail to poor material or slighted workmanship. It has the following desirable features: Simplicity of construction, attractive appearance, the moving system always entirely visible, a proportional scale, a damped system and quick working, strong suspensions that allow no zero shift, ample coil clearance and a sensibility that is ample for all ordinary electrical measurements and many precision measurements.

MORGAN & WRIGHT TAPE IS GOOD TAPE

Possesses exceptional adhesive qualities.
Will not dry out.
Unrolls smoothly and easily.
Has uniform insulation.
Is peculiarly free from pinholes.
Has high insulation resistance.
Is capable of withstanding extreme heat much longer than is required by the most severe tests.
Possesses an uncommonly high percentage of insulation composition.

Samples and prices furnished on request.

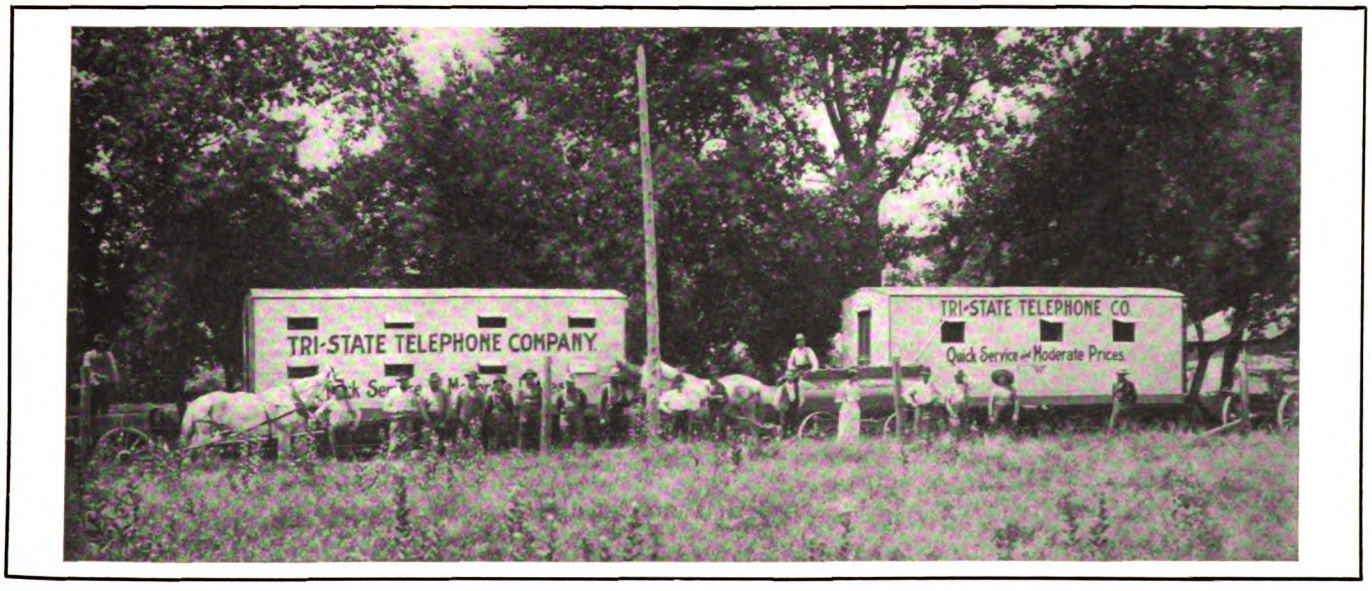
THE CONSTRUCTION WAGONS OF THE TWIN CITY TELEPHONE COMPANY

By Edward A. Tyler.

THE construction of long distance lines through sparsely settled districts offers some problems which are entirely new and not met with where the lines traverse a thickly settled country. The accommodations for the crew, such as sleeping quarters and meals, are often difficult to obtain, and even where they are satisfactory quite a great deal of time is often lost in going to and from work. To overcome this difficulty in the construction of its system through Minnesota and North Dakota, the Twin City Telephone Company has impressed into the service some wagons which offer a solution to this problem. The accompanying illustration will give a good general idea of their construction. They were designed by L. D. Richardson, General Superintendent of the Twin City Telephone Company, and built at the company's shops at a cost approximating $150 each.



Sleeping and Dining Wagons of the Twin City Telephone Company.

These wagons are arranged to accommodate sixteen men; one being used for the dining room and kitchen, the other for the sleeping quarters; each wagon is 8 feet wide, 26 feet long and 7 feet high, and is mounted on low trucks with wide tires, which offer a large bearing surface to the roadways, and reduce the amount of power necessary to draw them over soft tracks which would occur were narrower rimmed wheels used.

The dining wagon has a kitchen in the front end occupying a space 8 x 8 feet, the balance of the vehicle being used for the dining room. In the sleeping wagon the berths are arranged in tiers eight on each side. Besides these wagons, the Twin City Company has two others now being used in the construction of its line from Minnesota to Grand Forks, North Dakota. These are constructed on the same plan as the ones described, except that the sleeping wagon is higher, having three tiers of berths accommodating twenty-four men. On good roads only one team for a wagon is required, but where the road is soft, it is necessary to double up by using two teams. As the work progresses each day the horses used in the construction of the system are utilized to draw the wagons to new locations.

The advantage of this method of taking care of the crews are obvious, but the most important one is that the men are always on the ground where the work is being done, and thus no time is lost in traveling. In some instances, tents have been used where hotel accommodation was not available, but it will be readily seen that that method of accommodating the men is not to be compared with that obtained by the use of wagons. This company will complete its season's work about November 15, during which time it will have constructed 600 miles of No. 8 and No. 10 copper lines. This amount of work was largely due to the use of these wagons, which have given unqualified satisfaction and have been in service continuously.

It is interesting to note in connection with the construction and maintenance of telephone lines the application of modern methods in travel. Some of the largest telephone companies have introduced the automobile for repair work on long lines. Other companies have supplied their troublemen with motor cycles, and where these are not practical a good, swift horse and strong vehicle are always ready to be sent at a moment's notice to clear a case of trouble.

The old way has given place to the new, and where formerly a line might be in trouble for several days, if not a week, before being repaired, it is now but a matter of a few hours till service is restored.

MAINTENANCE.

ARTICLE III.

By Arthur Benson.

GROUNDS.—The efficiency of the ground wire depends entirely upon the character of the connection between that wire and the ground, and therefore the utmost care must be exercised in performing this work. The office that the ground connection is to fill consists in carrying off high potential charges from the line, before they reach the subscriber's telephone, and thus to preserve that piece of apparatus and the subscriber's

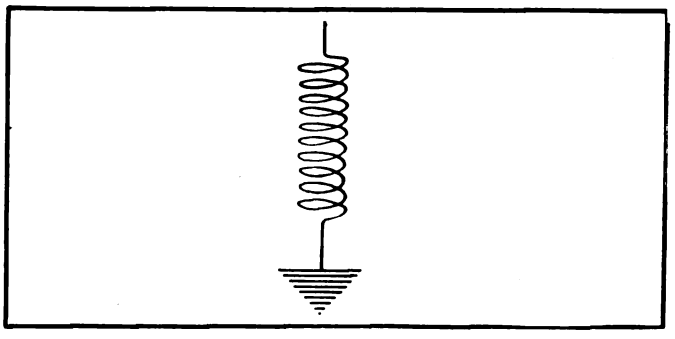

Fig. 4.

premises from destruction by fire. By far the most frequent cause of high potential charges on the line is lightning.

The features of the ground circuit are as follows: First: The ground wire shall be of sufficient size to carry off the largest possible current due to the charge. Second: Since the resistance of a wire to the flow of current increases with its length, the ground wire must be as short as possible. Third: Since the current flow due to a lightning charge is of the nature to set up a magnetic field in the surrounding air, which tends to retard its flow, and since this retarding effect increased with the number of turns or kinks in the wire, the latter should be run over the most direct path possible to the point where it is to make contact with the earth. All spiral twists, such as it used to be the fashion to make in the early days of the art, and a sample of which is shown in Fig. 4, must be avoided. Fourth: The contact between the wire and the earth must be permanent, and proof against mechanical injury, and of such a nature as to offer practically no resistance to the flow of current.

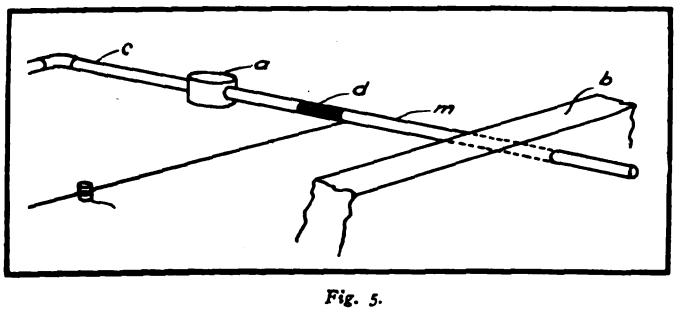

Fig. 5.

The first duty of the instrument setter, before he locates the protecting device, is to determine where the ground connection, or "ground," as it is called, is to be situated. He should then place the protection device in such a manner that the ground wire will be as short as possible. For example, if he has determined to locate the ground at a certain point in the cellar of the premises, the protector should be placed also in the cellar, and as near this point as possible. On the other hand, if the ground is to be located outside of the building, it will probably be best to locate the protection also on the outside. It must always be remembered that the ground wire must be the shortest possible.

Speaking generally, and leaving out of the consideration for the present, particular cases, there are two good ways to make a ground connection. First: By attaching the wire to a water pipe. Second: By attaching the wire to a copper plate sunk in moist earth. When the water pipe ground is used the following points must be observed. The wire must be attached at a point on the pipe, between the meter and the street main. The surface of the pipe where the attachment is to be made must be scraped bright and clean, preferably with a file. The wire must be thoroughly cleaned of insulation, scraped bright and wrapped firmly around the pipe twenty times and soldered. The joint must be thoroughly taped. In Fig. 5 is shown a ground connection to a water pipe, made in the proper manner. Here, the meter is shown at *a*, the pipe for house service at *c*, and that leading through the foundation wall *b* to the street main, at *m*. The ground wire fastened to a split knob insulator *e* attached to the ceiling beam, is shown wrapped twenty times around the pipe at *d*, which point is situated between the meter and the street main.

It is possible to solder the wire to the water pipe, without turning off the water, notwithstanding the fact that many stories are circulated to the contrary. To perform this work it is necessary to use a blow torch so that the surface of the pipe to which the connection is to be made shall be heated to the proper tem-

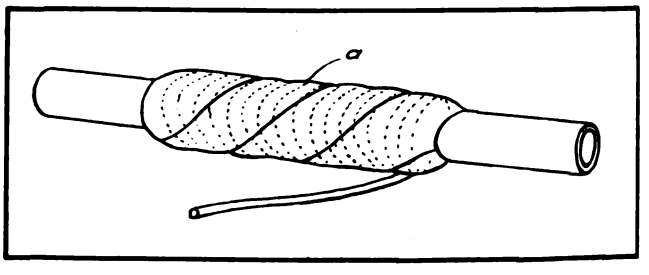

Fig. 6.

perature quickly so that the heat may not be conducted off to the portions on either side. The pipe must be heated sufficiently to cause the solder to run freely between the turns of wire. When the joint has cooled, the tape should be wrapped on.

It is sometimes impossible to make a soldered joint, owing to the belief that some building owners have that such joints injure pipes. In such cases it is necesary to wrap the joint tightly and carefully with tinfoil, so as to exclude the air and prevent corrosion. The tape is then layed on over the tinfoil. The tinfoil selected for this purpose should be free from dirt, paper or any foreign matter, and have a bright, clean surface. A joint of this description is shown in Fig. 6, where the tinfoil wrapping is shown at *a*, through which can be seen the convolutions of the wire. Grounds should never be made on lead pipes without first obtaining the sanction of the authorized superior officer.

Where the ground connection is made directly with the earth, two methods are used. Where the earth is moist the plan to follow is to sink to the depth of 6 feet, a copper plate 1 foot square, and about 1/16 inch in thickness, to which the ground wire has been soldered. Such a plate is shown at *A* in Fig. 7. The ground wire *c* is soldered by passing its end through a hole *b* in the groundplate *a*, bending the projecting portion so as to clamp the plate tightly, and applying the solder.

Where the ground is of a dry, sandy nature, a hole is dug to the depth of 6 feet and the copper plate, with the ground wire properly attached is lowered to the bottom. A bushel of charcoal or coke is then placed on top, care being taken to pack it firmly

Digitized by Google

around the plate, and the earth then filled in. Such a ground is shown in Fig 7 at *B*, where the wire is seen at *a*, the plate at *b*, and the charcoal or coke at *c*.

Wherever the installation is adjacent to running water, such as a creek, inlet or river, a good ground can be obtained by lowering the ground plate to the bed of the water. In doing this, however, care must be taken to ascertain that the level of

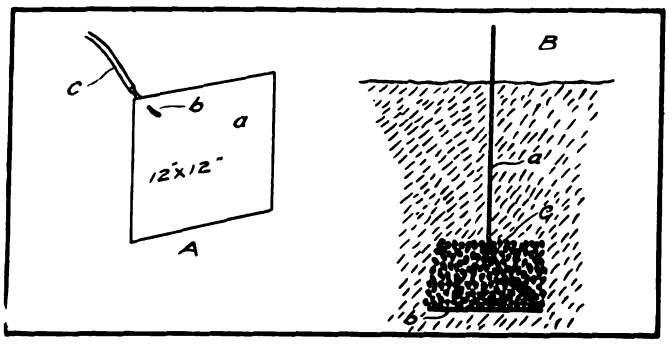

Fig. 7.

the water will never sink sufficiently to expose the plate, as should this happen the ground will become useless. Grounds should never be made in cisterns, since the rocks or cement with which they are lined form good insulators, and serve to break all electrical connection with the surrounding earth.

Ground connections should never be made on gas pipes, as they are often very poorly connected to the surrounding earth; and as a piece of advice which may appear unnecessary to the majority of instrument setters, but which experience has shown to be very necessary to some, let it be added that they should never be made to safes, or water coolers.

In running the ground wire care must be taken to support it on porcelain knobs, to keep it separated by at least 3 inches from pipes, and to bush all holes through which it passes with circular loom, hard rubber or porcelain.

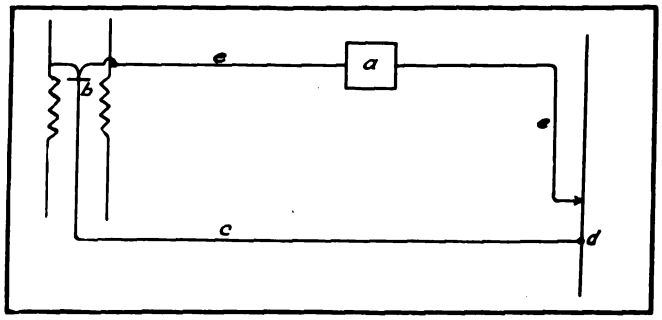

Fig. 8.

Afer the ground connection is completed it should always be tested by connecting one pole of the test set to the ground plate and the other to the pipe and ringing. The circuit through which the ring of the buzzer is obtained is shown in Fig. 8, where the ground plate of the arrester is shown at *b*, the ground wire at *c*, which is soldered to the pipe at *d*. The test box is shown at *a*, and the testing wires at *e*. If the ground connection at *d* is defective the buzzer will not ring.

SPECIAL BRIDGE CROSSINGS

By Harold A. McMann.

SPECIAL cases in pole line and open wire construction constantly confront the modern telephone engineer. Bridge crossings, either aquatic or on terra firma, offer quite a field for ingenuity in this line of work, and many novel schemes appear.

Take, for instance, a railroad bridge that crosses a road upon which a pole line is to be built.

and the crossing made directly over the tracks; both of these methods would probably necessitate extensive guying.

Probably one of the best ways of eliminating the use of poles altogether in similar cases is to use special cross-arm supporters or suspenders.

The general idea is clearly shown in Fig. 1.

The principal parts of the contrivance are the wrought-iron

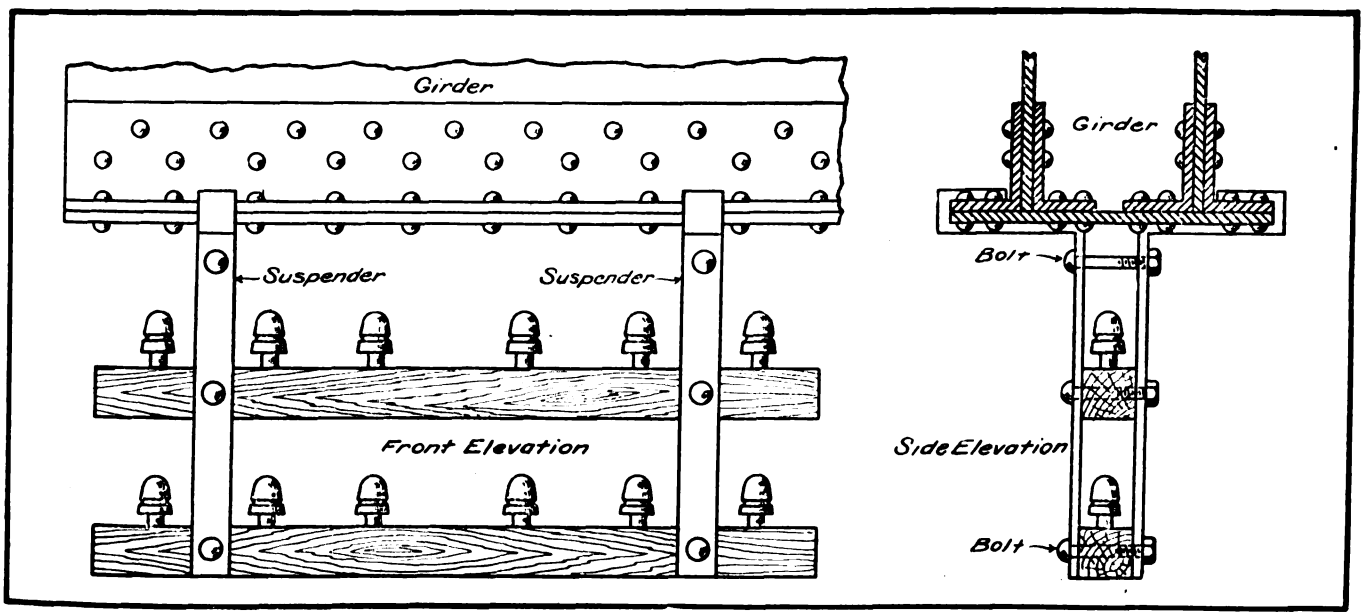

Fig. 1.

If the clearance between the bottom of the girders and the surface of the road is, say, 30 or 40 feet, it is a simple matter to run the wires under the bridge, using possibly 20 or 25-foot poles.

Then, again, if the bridge is quite low, higher poles can be used

straps. These should be from ⅜ inch to ⅝ inch in thickness, according to the number of arms they have to carry, and about 2½ inches to 3 inches in width.

The upper portion of the strap is bent to conform to the general shape of the girder.

Digitized by Google

The straps should have ½-inch bolt holes bored in them, to attach them to the girder and to hold the arms. The approximate locations for these holes are shown in the drawing.

Standard cross arms are used, holes to accommodate a half-inch bolt being bored in them between the pins.

The straps are first slipped on the girder and bolted in place; then the cross arms are put in position between the straps and securely bolted.

The length of the straps is determined by the number of cross arms to be used, the distance between the arms being about the

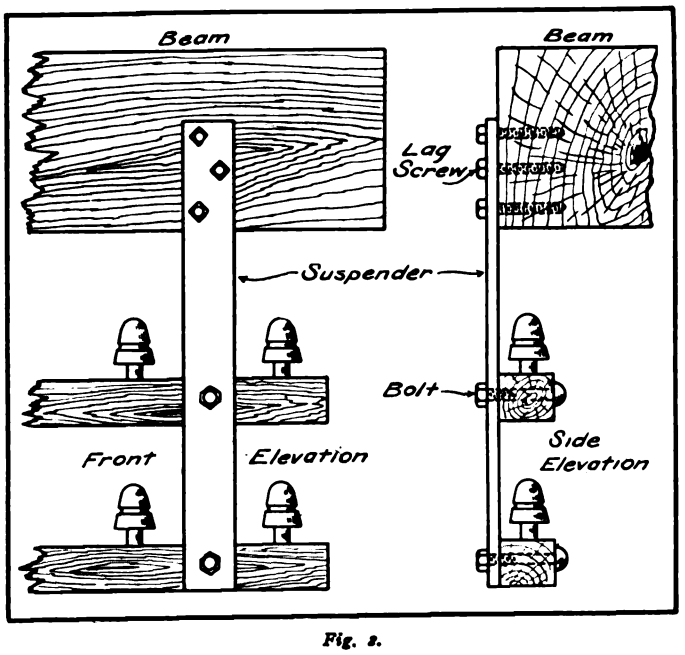

Fig. 2.

same as on a pole. Two sets of straps will generally be found sufficient to hold four or five, six to ten pin arms.

A method of attaching straps to a wooden bridge is shown in Fig. 2; only one pair of straps in this case is needed.

The straps do not have to be bent, being simply screwed to the wooden beam with two or three ½-inch lag screws, and the cross arms being attached as specified above.

For an ordinary bridge of from one to four tracks, one of these fixtures on each side will be found sufficient.

Two coats, at least, of metallic paint should be applied to the straps to prevent rust.

A method of crossing a river by attaching poles to a bridge is shown in Fig. 3.

In this case ½-inch wrought-iron straps about 4 inches in width are used, being bent to conform to the curvature of the pole being used, leaving a tangent of about 15 inches for attaching to the posts of the bridge. Four or five holes should be bored for ¾-inch lag screws.

Two straps should be used for each pole, unless the line is very heavy when more would be necessary.

After the poles are clamped in position with the straps, a few

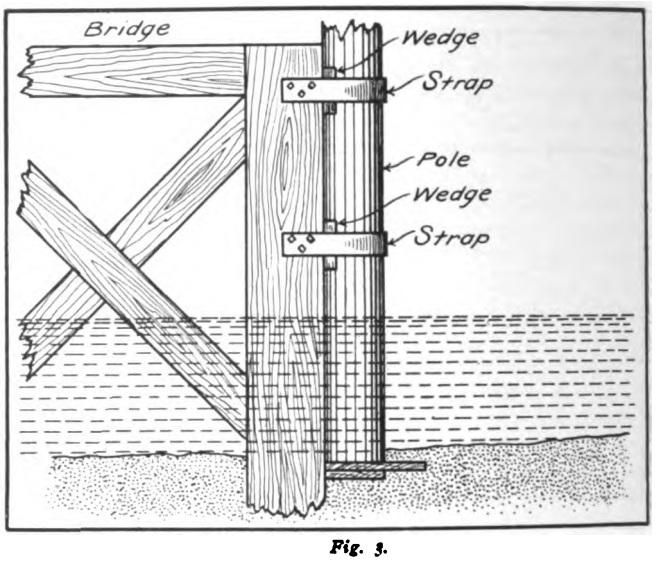

Fig. 3.

wedges of creosoted wood should be driven between the pole and the strap to eliminate the possibility of the pole slipping.

If the bridge is low and the water quite shallow, say 6 feet, the poles may be planted directly in the bed of the river. To

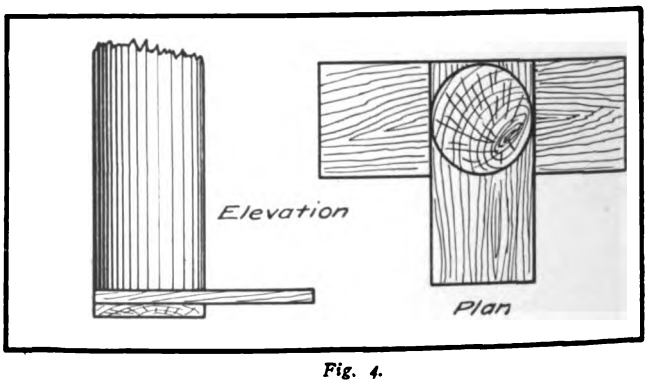

Fig. 4.

prevent undue sinking of the pole, a sort of float or platform may be improvised out of some 3-inch creosoted planks and fastened to the butt with heavy nails or lag screws; this arrangement is shown in Fig. 4.

INTERIOR BLOCK DISTRIBUTION

By Frederic D. Bond.

THE chief problem in telephone construction is to so build as to give the best service at the lowest equipment and operating costs. In an attempt to solve this problem a host of minor changes in building and working telephone plants are every year initiated, and within the last few years many companies have tried a new plan for the more economical distribution of the lines in crowded cities. This is known as Interior Block Distribution.

By the old method system each pair ran directly from a terminal situated on a street, or preferably on the corner of two intersecting highways to the subscriber's premises. This arrangement was the same whether the pairs came from an underground conduit or an aerial line.

In many cases this plan of distribution may prove desirable; but it became evident some years ago that there were a number of instances in which it could be improved on. In the first place, access to buildings is often difficult to obtain where the lines run directly to a street terminal; then the number of pairs open to trouble is manifestly larger in a crowded block.

The old system of distibution was open to the charge of incurring useless expense in many instances. A larger amount had to be expended in wire, rights of way and construction in this plan than required by the new block system of distribution.

Figure 1 shows the general plan of a system of interior block distribution. A cable leaves the terminal box at the corner of two streets which may be called Spring and Montgomery. En-

Digitized by Google

tering a building it runs through the basement and ends in a cross-connecting box on the rear wall of where it divides into ,two smaller cables which branch out in different directions over the interior of the block, to feed the substations.

Fig. 2 gives the cable plan. Fifty pairs come from the street terminal in a cable. At the cross-distributing box, half of the pairs go into line "A" and the other half into line "B," an extra pair being allowed in each of these smaller cables to locate trouble.

These two cables now run around the rear of the houses, some times on the falls and some times on the fences. In choosing location for the cables the engineer is guided by practical construction. He may place the cable on the side of the

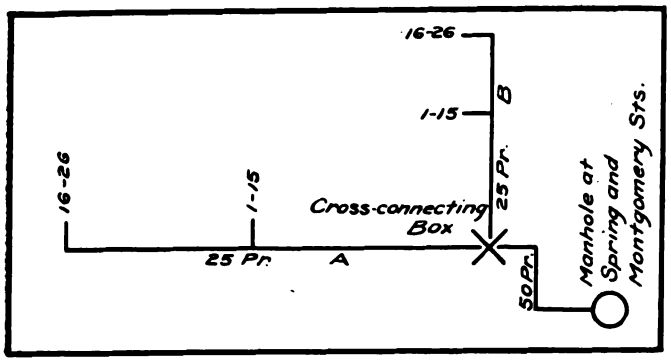

Fig. 1.

fence, or on its top, or attach it to the outer wall of a building, or do any, or all things that convenience suggests. Usually, it is easy to procure rights; frequently, indeed, owners will give it for the asking, and when refused, there is the advantage that new places are always on hand.

In considering the advantages of interior block distribution, it should be kept in mind that the benefits are always of a relative nature, and that no scheme of running wires from terminals to substations is conceivable that does not involve difficulties that the engineer would prefer to avoid. Nevertheless many of the difficulties of distribution are got rid of by the block system.

Probably the greatest objection to the old plan has been the difficulty with underground wires, of getting direct access from the terminal to each substation. The interior plan is much easier. First was the difficulty of entering the house; occasionally this could be done by aerial pairs issuing from the top of a terminal; but usually in a city it was necessary to pierce the walls of as many buildings as there were substations. Oftentimes, the character of the ground itself rendered the proceeding a difficult one, and owners would frequently object. But the greatest attendant expense was the necessity of tearing open the street every time a pair was to be run from a conduit.

By the block system the entrance into all the houses, except

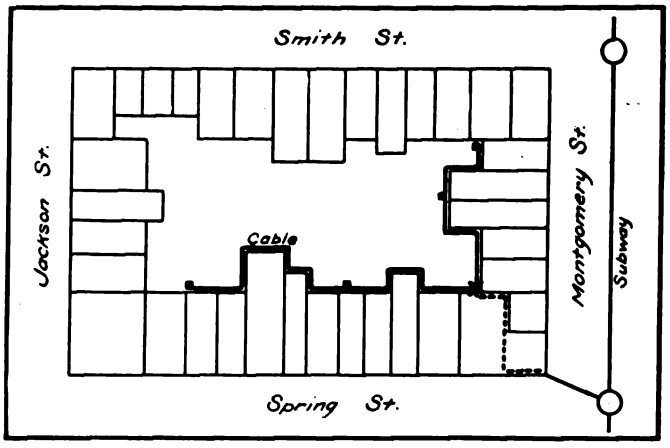

Fig. 2.

the one traversed by the cable immediately on its leaving the terminal is effected by an aerial line running from one of the distributing points on back fence or wall. This removes any necessity for any street work. The street need be torn up once only. A large enough cable is run from the start to accommodate all the subscribers the block is likely ever to possess, and so the greatest difficulty in the old plan is avoided at the outset. Then, when a subscriber wants service discontinued, it is hardly needful to point out how much more easily this can be properly effected under the conditions of this system than under the other.

A PECULIAR ACCIDENT.

A PECULIAR incident which recently took place in Indianapolis, Ind., is attracting the attention of telephone men and the public generally. The circumstances in the case were these: James Adams, of 1624 Cornell avenue, was standing at an office desk on which were two telephones, one belonging to the Indianapolis Telephone Company and the other to the Central Union. Having occasion to call a party he took up the telephone belonging to the Central Union Company, but failing to get the number tried the telephone of the Indianapolis Company. Both were metal desk stands, and it happened that their bases were touching. Adams took the receiver from the hook of the Indianapolis telephone and, while waiting for the number, rested his chin on the top of the Central Union instrument; a shock resulted that rendered Adams unconscious, causing him to fall to the floor. When revived, on attempting to move it was found that he was paralyzed from his waist to his feet, and at the same time he suffered a great deal, and it was thought that he would die.

The wire chiefs of both the companies advanced the theory that Adams was stricken with paralysis while standing at the telephone, and that the shock received, if there was any, had nothing to do with his condition. It was found that the wires were safe from contact with other wires and that the current was not strong enough under any condition to produce results that would cause paralysis. It was claimed that if the operators at either of the exchanges had rung the telephones while Adams was in the position described that an electrical pressure of about 75 volts would be given; but this is not probable, and even 75 volts is not enough to harm most people in the slightest degree. On the other hand, the attending physicians state that Adams was in perfect health, and they believe that paralysis resulted through a shock received from the telephones. Mr. Adams is gradually recovering use of his legs, and his ultimate recovery is looked for, but in the meantime this unusual accident is causing a great deal of comment among physicians and wire chiefs throughout the country. The officials of the telephone companies are at a loss to know what caused this accident, as the wires have been examined and found protected in a thorough manner.

AN INDEPENDENT SYSTEM FOR DALLAS.

A MASS meeting was recently held in Dallas, Tex., for the purpose of considering a proposition offered for an Independent telephone company. The meeting was addressed by several influential citizens, among them being Gen. M. M. Crane, Capt. A. J. Brown, Dr. C. M. Rosser, J. W. Blake, Judge Aldredge, Frank Irvine and C. A. Keating. All of the above, with one exception, were in favor of a competitive system, and brought a number of instances to bear upon the subject.

The company which is endeavoring to secure a franchise promises to expend three-quarters of a million dollars in improvements incidental to the construction of the system, besides paying $1,500 for the first period, $2,500 for the second, and $3,000 for the last. J. W. Blake made a telling argument in favor of an Independent system, citing instances where two telephones had been of immeasurable benefit in securing better service, lower rates and increased facilities. The matter will be submitted to ward meetings, and it is expected an Independent franchise will be granted.

A TYPICAL YEAR'S WORK OF AN INDEPENDENT COMPANY

The following annual report of the Home Telephone Company, of Jasper County, Missouri, showing results obtained under progressive administration, has just been submitted by President Theodore Gary to his stockholders. It is republished practically in full as a fair example of the kind of work that is being done to-day in the Independent field.

THE work of rebuilding the Joplin plant has been finished. The Webb City plant has been practically rebuilt from one end to the other. Forty-five hundred feet of cable put in, new poles set, and the entire plant made metallic. Central office moved into a substantial building. Plant is well equipped now, notwithstanding the fact that the Bell Company recently put in a central energy plant at this place, (you remember we had no competition until during the last year), we are making a very substantial increase in our subscribers. We have 312 subscribers in Webb City against 280 a year ago, and we have sufficient switchboard and cable capacity for upwards of 400 telephones.

Carterville has a completely rebuilt central office. We have considerable excess switchboard and cable capacity at this place. Plant is in good shape. We have 165 subscribers here against 140 a year ago. Here, too, the Bell Company have put in a new plant, they not having one here before this year. In face of the fact that the Bell has a central energy plant here our business is increasing and at no time in our history have we had such a demand for new telephones as at this time.

The Carthage plant has been practically rebuilt throughout; have put in that exchange about 20,000 feet of new cable; have some 4,000 feet yet to go up. By special arrangement we have built a one-story and basement building; first floor is up about five feet from the sidewalk, and occupied exclusively by the company; stands on a lot 50x200 feet, on which we have an option to purchase at $5,500. Plant is in excellent shape.

In addition we have lately made arrangements to connect 100 farmers in the northeast part of Jasper County with Carthage Central for a term of twenty-five years on very advantageous basis, both to our local subscribers and the company. Since our last annual meeting, we have the long-distance connection with Kansas City and St. Louis by the Kinloch Company over a line that was built from St. Louis direct to Joplin, at a cost of over $800 per mile, that being the southwest terminus of their line. It is said to be the best line ever built in the United States. This contract runs for twenty-five years. Have lately entered into contract for toll connection with southeast part of Kansas and the northern part of Indian Territory. In addition, have a contract with Springfield for a toll connection to run twenty-five years. This will give us very good outside connections.

In addition to rebuilding the several plants, we have been able to reduce operating expense considerable. At Carthage a new board has been installed and where it used to take seven operators at one time to handle the business we now have but five, but do the work as well or better than we did before. At this place the Bell is making a vigorous effort to increase their list, and even offering free service until they have 200 subscribers. They have just completed the rebuilding of their plant at this place. We have over 700 of our own, besides 100 others, making over 800 connections in Carthage for our subscribers. Besides, we have other facilities to be put in force at Carthage that will enable us to earn $1,000 more net a year without any further investment. At Joplin, changes have been made in the rates that amounts to 50 cents a month for residence and 50 cents a month for business, increase for single line, which makes our rates *50 cents more both for residence and business service than the Bell are charging now. Notwithstanding that fact, we have a large waiting list and more orders than at any time in the history of the company.*

Up to this time we have never paid much attention to increasing our list of subscribers, as it was found early that an improvement in rates and earning capacity of plants was absolutely necessary before any new business can be handled profitably, therefore the management has devoted more attention to increasing the earning capacity than the number of telephones.

The improvements have been made to all the plants with a view of increasing the business without a great increase in the outlay. It is confidently believed that 1,000 subscribers can be added to the plants with an expense of not exceeding $25,000, owing to the fact that the switchboard and cable capacity is sufficient in most places to take care of an increase, if fairly well distributed over the system. This will greatly increase the income, without a comparative increase in the outlay. The management expects to make a very satisfactory showing during the next fiscal year, owing to the fact that the demand for telephones was never better or the service of the company excelled, and the company just ready to profitably increase its business.

The telephone situation has greatly improved. The Kansas City Company has in excess of 9,000 subscribers, and has extended its toll lines in various directions, connecting up the adjoining towns with more than 50,000 Independent telephones tributary to Kansas City, all of which have been bound together by long-term contracts running from twenty-five to forty-nine years. While the companies are owned by individuals, they are operated as one company. The telephone situation in the vicinity we are operating is the most favorable, conditions exceptionably favorable for active business, and the management can assure the stockholders that there is no lack of business in the districts and territory the Home Company's plant cover. The only question for the management to solve was how to handle this business at a profit, and that has been the main question heretofore under consideration. We feel that we have the plant on a basis that we can increase the business by one-half to two-thirds at a profit.

When the plants were consolidated two years ago the nominal number of telephones used was 2,135, at an annual rental of $42,218, or an average income per telephone of $19.72. In spite of the stiffening of rates and more or less interference with the service by rebuilding, etc., our subscribers have been increased to 2,285, or an increase of 150. While the increase in number has not been large, it is entirely satisfactory to the management. The earning capacity of the plant October 1st was $51,184, or $22.40 for each telephone, or a net gain per telephone of $2.68. A total increase in earning power from $42,218 to $51,184 being $9,966 increase in gross receipts. It will be impossible to give a comparative statement of net earnings on account of the fact that the old company did not properly classify their several disbursements, but a comparison of the gross and net earnings for the past two years are as follows:

Income 12 months ending September 30,	1903.	1904.
Expense, maintainance, etc.	$42,147.00	$46,949.69
About 63 per cent. of income 1903 } About 55 per cent. of income 1904 }	26,038.00	25,781.98
Net earnings	$16,111.00	$21,167.80
Net gain in net earnings over 1903		5,056.80

Financial Statement of the Home Telephone Company of Jasper County, Mo.

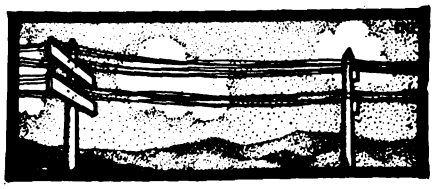
QUERIES

Questions on any subject relating to telephony will be answered on this page.



SERIES INSTRUMENTS ON PARTY LINES.—(449.)

I enclose herewith a diagram for using series telephones specially wound for use on party lines. Can you tell me whether this system will work properly or not? C. B. H.

While it might be possible to operate the circuit you describe, yet we doubt if any good results could be obtained if the line was any length at all. The circuit, as shown in Fig. 449, would probably be noisy. Furthermore, we note that you use all your bells on one side of the line to ground, and therefore the system is, under these circumstances, non-selective. Again, in ringing the distant instrument, on account of the low resistance of the bells, the ones nearest the station ringing would receive all the current, and we doubt whether the generators would be able to supply enough current to ring the bells satisfactorily. We would suggest using a selective party-line system which contains high-wound bells and an ohmic resistance of from 2,000 to 5,000 ohms to ground.

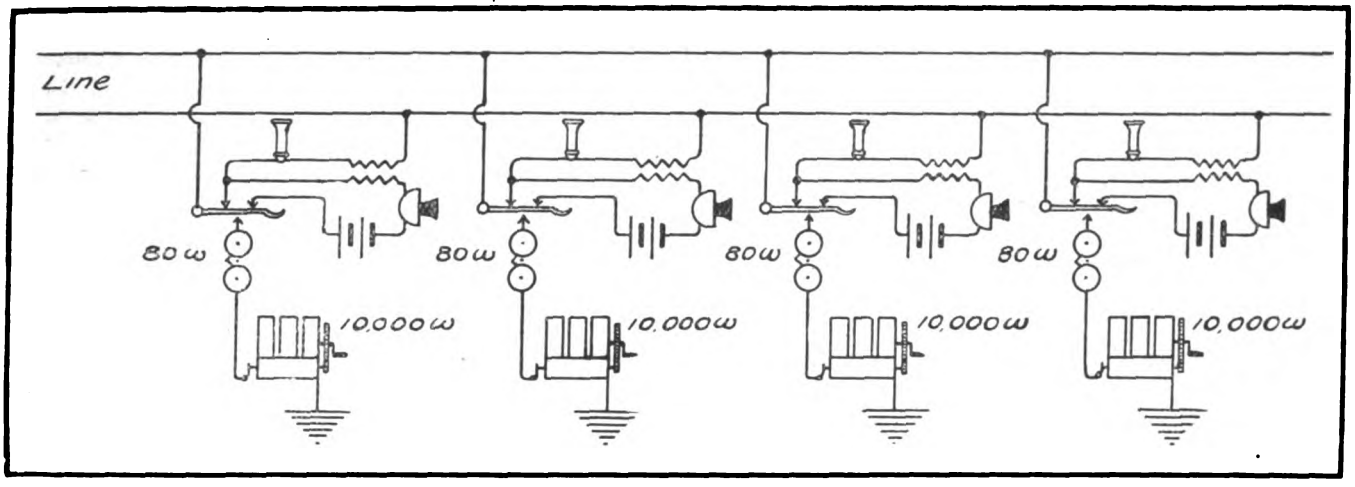


Fig. 449.

We see no advantage in installing the circuit in the way you suggest, and think you would do better to follow the standard practice.

POLE SETTING.—(450.)

How can I set a pole in soft ground without it sinking in? We have a long line contemplated which we can save a lot of wire upon if you can offer a solution. G. L. L.

One of the best methods is illustrated in Fig. 888. Set the pole

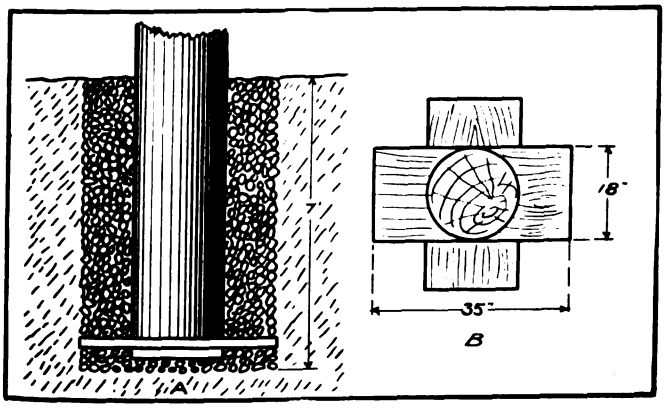

Fig. 450.

in a concrete envelope composed of rubble; one part cement, two parts sand, and four parts stone. To the bottom of the pole a platform should be attached, as shown in the figure. This eliminates all possibilities of the pole sinking and at the same time the use of the concrete secures a foundation which has a great amount of stability.

GROUNDED CIRCUITS.—(451.)

We have three grounded circuits on the same poles, two circuits, No. 14 wire, one circuit No. 12 wire running three miles. At this point, the No. 12 wire branches off, covering an area of twelve miles with fifteen instruments. The two No. 14 wire lines parallel for two miles, and one of them continues three miles further on, and is used as a toll line, the other has six telephones connected to it. The No. 14 wire is old and rusty, the No. 12 wire is new. We have trouble in ringing. What would be the cause? We hear cross-talk or induction from the No. 14 lines on the No. 12 wire line very plainly. Is this due to the current taking the path of least resistance? J. E.

In the first place, with grounded circuits it is impossible to get rid of cross-talk on account of induction; the only remedy is to make the circuits metallic and transpose. The number 14 wires being old and rusty probably offer a very large amount of resistance at the splices. This would account for the difficulty in ringing the distant parties. In the case of the number 12 wire, if the resistance of the ringers is low it will be impossible to ring them successfully because the generator you employ does not furnish enough current for the purpose.

The resistance of instruments on this line should not be less than 1,600 ohms, and it would be much preferable to have them of 2,500 ohms. We believe that it is absolutely essential that the toll line should be made metallic, because it is liable to transmit to a much greater extent the inductive disturbances from one system to another if it is grounded. The old No. 14 lines should be replaced or else all the joints resoldered.

LINE CONSTRUCTION.—(452.)

We are going to build a telephone line. About how far apart should the poles be spaced? Should we use brackets or cross-arms?

The standard practice in pole line construction is to space the poles about 40 to the mile, although in turning corners the number may have to be increased. If iron wire is to be used, 35 poles to the mile might be sufficient. If the pole line will never carry more than two wires brackets might be used, but it is much preferable to use cross arms, as should the contingency arise necessitating a new line there would not be the cost of replacing the brackets with arms.

RESPECTFULLY SUBMITTED TO OUR BELL FRIENDS.

IN another part of this issue there appears the annual report of President Theodore Gary to the stockholders of the Home Telephone Company, of Jasper county, Missouri. We commend a careful reading of this report to our friends in the Bell ranks, as well as to our friends, the Independents.

We have had much to say during the past two years about the Bell press bureau methods. We have pointed out rather sharply the dishonesty involved in circulating, through the medium of newspapers that are willing to sell their columns for a price, false statements concerning the progress and financial standing of Independent telephone companies. It is too much to expect that the exposures we have made from time to time in this regard are going to result in putting an end to this method of press campaigning on the part of the Bell interests. Our main object in meeting these false statements in print, has been to furnish ammunition to those Independent companies that are made the victims of this sort of work. It has been our hope that the Independent companies, having behind them the support and good will of their neighbors, would be in a position to secure the aid of the honest newspapers in their vicinity, providing the right sort of material was furnished, and that in this way the evil effects of the Bell literary bureau could, in a measure, be offset. Nothing is easier than to meet the Bell misstatements, as the Independents can draw on their own experience for facts and figures that will confound their enemies. It is because we believe that in the report submitted by Mr. Gary, there may be found such material that we reprint it. It is not made public because it is exceptional or extraordinary, but because we believe it reflects the general condition to be found to-day in the Independent industry. And it is only necessary that facts such as these be presented to nullify absolutely the influences that the paid articles put out by the Bell are supposed to exert.

Mr. Gary, as much as any other man in the Independent ranks, has felt the influence of the underhand Bell methods. His territory, both in Jasper county and in Macon county, has been literally flooded with anonymous matter, put out for the purpose of frightening would-be investors in Independent securities. Capital is proverbially timid, and especially susceptible to attacks of this kind. It is not surprising, therefore, to find Independent companies hampered here and there for capital to meet extension demands, notwithstanding that they can show the enormous profits that would come to them from the building of such extensions. What, for instance, could be more inviting to capital than the condition described by Mr. Gary in the concluding section of his report, where he says that 1,000 subscribers can be added to his company's system to-day at an expense not exceeding $25,000, or at the rate of $25 each, owing to the fact that the improvements already effected were especially planned to take care of increasing business without much increase in the outlay. As the average receipts in this system are now at the rate of $22.40 for each telephone installed, it will be seen that in the addition of the 1,000 subscribers alluded to, the company would almost clear in the first year's rental the total investment required for this extension.

Another significant section of the report to which we would like to call special attention is the fact that though the rates in Joplin have been increased $6 a year and that they are now $6 a year higher than the Bell rates, Mr. Gary's company has a large waiting list and "more orders than at any time in the history of the company.

AN ILLUSTRATION OF INDEPENDENT FINANCE.

As we have said before, the conditions shown by this report are not exceptional. We doubt even that it represents on the whole the average condition in the Independent industry, for the plants which Mr. Gary and his stockholders consolidated, were in rather a bad way, and the process of reorganization under the present management has been in force a comparatively short time. Surely an industry that is built on so solid a foundation can get all the capital required to meet its growth. It is only necessary to spread the facts before the people, to educate the bankers and investors, to insure more money than is needed.

NOT INSTALLING LIGHTNING ARRESTER.

FRANK B. WOODBURY, of Syracuse, N. Y., has commenced suit against the Empire State Telephone and Telegraph Company for damages he claims to have received by the destruction by fire of his new chair factory.

On the evening of June 14, a heavy electric storm passed over Orwell. Between eleven and twelve o'clock that night there was a blinding flash of lightning and a terrific roar of thunder, it is claimed, and almost immediately flames burst out in the factory. All the building, it is claimed, was dark except where the telephone wires entered and there was the starting point of the fire. It is also claimed that lightning struck the telephone wire some distance from the factory, shattered the poles and entered the building.

The telephone company is charged with the blame. It is asserted that the company was negligent and careless in failing to install the usual lightning arrester with the usual ground wire and in failing to put the ordinary insulation about the wires which entered the building.

There is a lesson in this suit that ought to appeal to every operating company. This is the wisdom of equipping a plant in all its divisions with proper protective apparatus. The cost of protection is so small relatively, when the possible damage which can occur due to lack of protection is considered, that it is hard to understand why any up-to-date manager will neglect this important part of his equipment. Whether the contention in this particular case is true or not makes little difference. In fact, the case in favor of protective apparatus is made all the stronger if the plaintiff's allegation that the fire was due to the telephone wires was untrue, for in that case if the telephone company could show that it had a lightning arrester in place the suit would be practically decided in advance.

AN IMPORTANT CORRECTION.

IN the address by Mr. C. E. Wilson upon Independent telephone securities as an investment the paragraph reading "I am one who believes that the Independent interests will put the Bell out of business" should read "I am not one who believes that the Independent interest will put the Bell out of business, or that the Bell people will put the Independents out of business." The omission of the word "not" entirely changed the construction of the sentence and its meaning.

The Telephone in the Courts

Conducted by A. H. McMillan.

Readers are invited to submit questions on any point of Telephone Law. They will be answered and explained on this page.

CARTY PATENT.

The American Bell Telephone Co. has in litigation now some case involving what is known as the "Carty Patent."

In order that we may be fully informed in this matter, won't you be good enough to send us at once the nature of the questions involved in this patent, as well as in the litigation? A. L. T.

THE patent to which you refer is, I believe, No. 664,175, its title "Telephone Exchange Apparatus," issued July 14th, 1896, to John J. Carty. A copy of this patent may be obtained by sending 5 cents to the Commissioner of Patents at Washington, D. C., and giving the facts enumerated above in regard to it. It consists of ten claims, the last of which I quote:

> 10. In a telephone system, the combination with a telephone line of a normally closed connection to ground at the central station containing a testing-battery, an operator's metallic circuit containing her telephone set, a ground connection from said metallic circuit, whereby said operator's telephone may be connected in said circuit with said testing-battery and a resistance included in said ground connection adapted to prevent the disturbance of the operator's telephone when in metallic circuit due to static changes passing to earth through said ground connection, substantially as described.

The suit has not yet been decided and until it is no report of it will be accessible from which I can tell the nature of the question involved.

WHO IS FIRST OCCUPANT?

Our company planned to build its line on certain streets and was given permission by ordinance of the council to do so. We notified the electric lighting company of our intention to do so and what streets we would occupy, and had actually begun to put up our poles and wires. The lighting company then commenced to put up its whole line on the same street, finishing its line before we could do any more work on account of a strike. Then we finished our line and found we were troubled with interference from the strong current of the lighting company's wires. Are we entitled to enjoin the other company from using the street on the ground that we are the first occupants? J. B. Co.

YOUR statement makes out a very clear case entitling you to relief. It was held in a similar case that a lighting company situated as your telephone company is was the first occupant. Reverse the positions and the case sustains your right to an injunction. Nebraska Tel. Co. vs York Lighting Co., 43 N. W. 126.

LIMITATION OF RATES.

Can you tell us through your paper if the constitution of the State of Illinois confers upon cities the right to regulate and fix charges for telephone service? Also if a company operating under a franchise which limits or fixes the price can legally raise those charges? What court decisions have been rendered on this subject in Illinois or in other States? S. County Telephone Co.

I KNOW of no such provision in the constitution of Illinois, and it would be an unusual clause to be inserted in the constitution of any State. A company operating under a franchise that fixes a limit to the rates it can charge is firmly bound by them and cannot lawfully charge more than is therein fixed. A franchise is in the nature of a contract between the city and the company, and, like all contracts, must be lived up to.

Aside from a constitutional provision, it is within the power of the legislature of a State to regulate the charges which may be made by telephone companies for the rental of telephones and for general telephone service and facilities, within the limits of the State, and a statute prescribing a maximum rental for such service is constitutional and valid. State v. Bell Telephone Co., 23 F., 539. Central Union Telephone Co. v. State, 123 Ind. 113, 3 Am. El. Cas. 529. Nebraska Telephone Co. v. State, 55 Neb. 627, 76 N. W., 171.

A municipality cannot regulate telephone rates, except it be given power expressly in its charter to do so. This will not prevent it from making a contract in the form of a franchise with a telephone company in which the rates are fixed. Power given to a city to "license, tax and regulate" telephone companies is not so construed to give the company power to regulate the charges for telephone service. City of St. Louis v. Bell Telephone Co., 96 Mo. 623, 2 Am. Elec. Cas. 44. Although a municipality has power to regulate and control the use of streets, yet this power will not confer upon it authority to regulate telephone charges. State v. Central Union Telephone Co., 14 Ohio, C. C. 273. Joyce, Electric Law, sections 521, 523, 525.

SENSATIONAL ARRAIGNMENTS OF COURTS.

A SENSATION was caused in Denver, Colorado, by an argument of counsel upon the motion for change of venue in a suit brought by John Hipp vs. Colorado Telephone Company, to force the telephone company to give lower rates to all of its patrons. The ground for the motion for change of venue was that the Judge was interested and prejudiced and that the counsel for plaintiff had an undue influence over the mind of the Judge to such an extent as to prejudice him against the telephone company. Plaintiff's attorney in his argument delivered a bitter arraignment of a portion of Denver's judiciary, of the legal machinery adopted in the District Court and the public utility corporations of the city. He said that these corporations were seeking to intimidate the Judge by charging that he had made places for his relatives, and that the speaker was forced to employ them when he received an appointment as assignee of the Court.

Said he, "That is the blackmailing power of the corporations. Your Honor is under the test. I demand justice in my rights under the statute to the very letter and I look to this court to get them." Judge Johnson, against whom the charges of partiality were made, dismissed the application for the change of venue, saying that he thought he was perfectly capable of giving the suit an impartial hearing. In discussing the charge the Judge said that it was true that several relatives of the plaintiff's attorney were holding positions in connection with the court, but he denied that the influence of the plaintiff's attorney had had anything to do with their appointment, and also said: "It is further charged that Messrs. Stuart & Murray, plaintiff's attorneys, have heretofore brought a number of suits against public utility corporations of this city, including the defendant company, and in each instance have made the effort, and have usually been successful, to have them assigned to my division; I have no knowledge of this charge, and this is the first time it has been presented to me. I desire to say, however, that I have never tried a case upon its merits against any of the public utility corporations in this city since I have been on the bench, covering a period of some ten years.

"Reference is made to a former case entitled Herbert George vs. the Colorado Telephone Company, wherein it is charged that I manifested unfairness in disposing of the same. I do not care to retry the case at this time, but say without any feeling of embarrassment that I tried it to the best of my ability and decided the matters therein strictly in conformity with the law as I understood it.

"I believe that the showing made is not sufficient to warrant a change of venue.

"Therefore the motion will be denied."

IN THE OPERATING FIELD.

REPORT OF DELAWARE AND MADISON COUNTIES TELEPHONE SYSTEM.

THE recent report of the Delaware and Madison Counties telephone system shows a gratifying increase in all departments over the same periods of last year. Below will be found a statement, which compares the months of September and also for a period of nine months ending with September:

	Sept. 1904.	Sept. 1903.
Income from rentals	$ 6,526.77	$ 4,442.50
Income from tolls	1,535.84	818.82
Income from building	135.00	135.00
Allowances	48.79	32.43
Gross income	8,148.82	5,363.89
Operating charges, taxes and insurance	3,853.36	3,593.39
Net income	4,295.46	1,770.50
Interest	1,744.16	1,487.50
Surplus for stock	2,551.30	283.00

STATEMENT FOR NINE MONTHS ENDING SEPT. 30.

	1904.	1903.
Income from rentals	$55,149.33	$35,946.80
Income from building	1,215.00	1,215.00
Income from tolls	11,427.58	5,472.29
Discount	149.90	7.96
Allowances	598.82	1,070.65
Gross income	67,342.99	41,571.40
Operating charges, taxes and insurance	33,210.57	24,406.88
Net income	34,132.42	17,164.52
Interest	15,560.85	11,467.01
Surplus for stock	18,571.57	5,697.51

A NEW MAINE COMPANY.

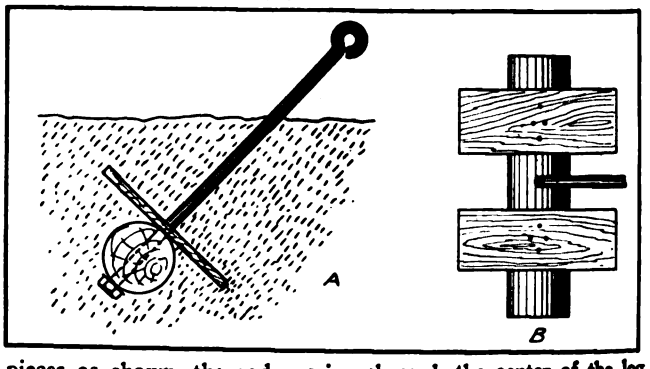
THE Union River Telephone Company, which has been organized to build telephone lines to connect up-river towns of Hancock County, has as its president and general manager for the first year Albert E. Mace, of Aurora; Dr. J. H. Patten, of Amherst, secretary, and H. T. Silsby, of Amherst, treasurer. The exchange will be located at Amherst and lines will be built to and through towns along the Union River. This new company will be of great advantage to the lumber men of this vicinity and is but the commencement for a system which will reach all of the towns in the lumber region which heretofore have been without telephone connections.

EXTENSIONS TO P. & A. SYSTEM.

ALL the important difficulties in securing rights of way for the new Pittsburg & Allegheny telephone line to Wheeling, in connection with the National telephone system, have been settled satisfactorily, and the line has been completed from Wheeling to Bridgeville. The work from Bridgeville to Pittsburg will be hurried, and it is expected that inside of thirty days the line will be in operation. This connection will open up a large and important territory covered by Independent telephones, with which the Pittsburg & Allegheny will have connection over a thoroughly modern line. Rapid work is being done also on the Pittsburg & Allegheny's new line to Butler. In fifteen days of work ten miles of this has been built, with all the material distributed. It seems probable that the entire thirty miles will be completed before Christmas. As on the other Pittsburg & Allegheny long-distance lines, a private right of way and a direct route have been obtained. This line will connect the Pittsburg & Allegheny with the Independent telephones in northern Pennsylvania, reaching the principal towns, such as Warren, Girard and Titusville. Ultimately it will be a link in the Independent route to Buffalo and other New York cities. The line to Johnstown, completed some time ago, has proved a financial success. The service given is satisfactory, and it is being used extensively by large concerns in Pittsburg and the other towns having interests in Johnstown.

TO FASTEN A GUY LOG.

WHEN guy logs are used it is important that they should be so placed as to offer the greatest resistance to a strain. The best method is illustrated in the accompanying figure. *B* represents the guy log, to which are fastened two cross



pieces as shown, the rod passing through the center of the log and fastened with a nut, as shown *f* at *a*. Its position when placed is shown at *a*, and is self explanatory.

TELEPHONE REGULATION IN SOUTH CAROLINA.

SOUTH CAROLINA has followed the lead of Louisiana and placed the regulation of telephone service within the State under the control of the Railroad Commission.

In several respects the law was found either too general or that certain sections of it failed to cover certain points, and the commission, from the decision rendered, will at the next session of the Legislature point out these defects and have them remedied. The law is particularly deficient in regard to a remedy for a raise in rates and leaves entirely too much to the judgment of the commission and the testimony of either side in the complaint.

There is now before the commission a question of the connection charges to be regulated between two systems doing business in towns close together. The matter has arisen over a dispute between two exchanges at Troy and McCormick, respectively. The commission has to take into consideration the fact that one exchange may have a hundred telephones and the other may have two hundred. It also has to consider that one may have connection with the whole surrounding country and the other may have connection with only a half dozen places.

EXTENSIONS OF UNITED STATES COMPANY.

THE U. S. Telephone Co. is making arrangements to extend its system of long distance lines from towns on the Eastern Coast to Chicago and the West. It has already secured controlling interest in a number of companies, and has traffic agreements with several others. A line is being built from Scranton to Buffalo, which will connect with Allentown, Easton and Bethlehem. By means of an agreement with the Interstate Telephone Co., towns in New Jersey will be able to reach the important cities of the Central States.

IN THE MANUFACTURING FIELD

"SUCCESS LIES IN THE KNOWLEDGE OF OUR TOOLS"

A NEW SELECTIVE SYSTEM.

ONE of the many problems which sprung up with the present widespread movement of telephony was the necessity for providing some means whereby one subscriber could automatically call another on a party line without signaling the exchange, or else to signal the exchange without calling any of the parties. Many devices have been designed to fulfil these requirements, the T. and A. Selective Call Company, of Geneseo, Ill., having just placed a practical piece of apparatus on the market which fulfils these requirements. Like other inventions, when properly worked out, this piece of apparatus is the acme of simplicity, and one is inclined to say, "why did I not think of it before?" Fig. 1 illustrates an ordinary magneto before and after conversion to this type of selective signaling. The part to which the wires are attached, shown in the left hand illustration, is a commutator so arranged as to give either positive or negative pulsations. The circuit of the sub-station generator is shown in Fig. 2, which also illustrates the strap keys by means of which either the exchange or a subscriber can be called. The only other piece of apparatus is a relay, which is so arranged as to respond to pulsations of predetermined polarity only. In its design, the manufacturers had in view that the least complication was required, so that but the slightest knowledge would be required to locate and clear trouble. With this end in view the relay is made with only three moving parts. The adjustment is based upon the action of a hanging weight; in other words, by gravitation. Only a small fraction of the current necessary to operate any other signaling apparatus is required and consequently the efficiency of the relay is very high.

This system is designed for either grounded or metallic lines as well as divided circuits. By a divided circuit is meant one in which a subscriber is able to ring the parties connected with one side of the line without disturbing those connected with the other. When a subscriber is signaling the exchange the bells of the other parties on the line are not disturbed in the least, and vice versa when the exchange is being called.

The most commendable feature of this contrivance is its adaptability to the present type of generators in use, thus eliminating the cost incidental to changing this part of the apparatus. From an operating standpoint it greatly increases the efficiency of a line, and at the same time materially reduces the time necessary to get into communication with a party on the same line, since it does away with the necessity of ringing the exchange. This system relieves the exchange operators of all necessity to watch or listen when a call is being made, since their attention is wanted only at such times as a connection is desired. It is possible to include in the circuit at the exchange an audible signal besides that made by the drop. This may be of any desired tone required, from that furnished by a buzzer to a 24" fire alarm gong. Wherever the apparatus has been demonstrated, its simplicity has been noted as a most remarkable feature, and a large number of repeat orders have been received resulting from the first one received.

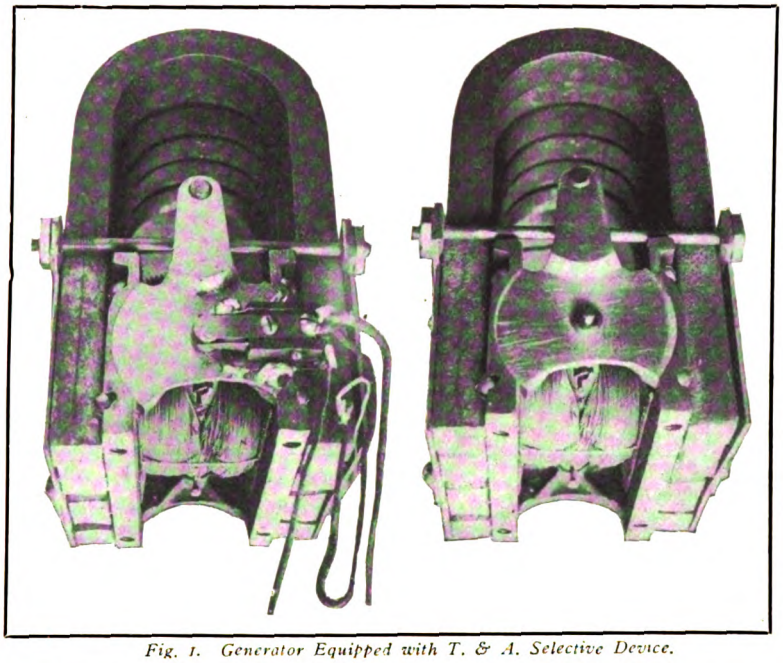

Fig. 1. Generator Equipped with T. & A. Selective Device.

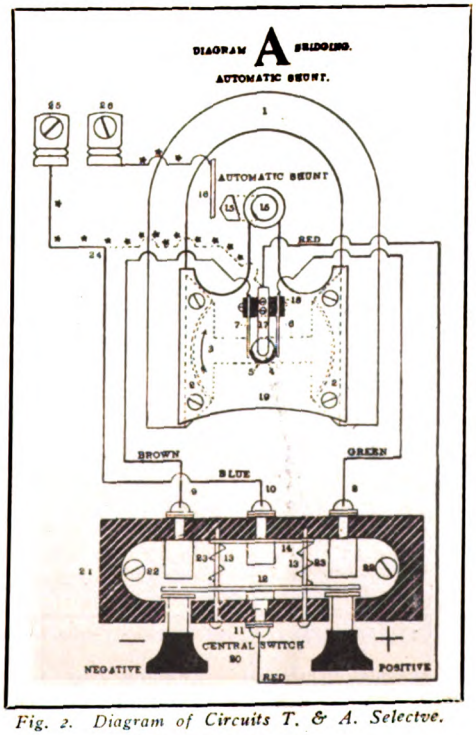

Fig. 2. Diagram of Circuits T. & A. Selective.

THE INTERNATIONAL TELEPHONE MANUFACTURING COMPANY, of Chicago, which is rebuilding the Public Service Telephone Exchange for the municipality of Neepawa, Manitoba, Canada, has secured, in addition to its contract for central office equipment, an order for subscribers' telephones, replacing those formerly in use. When the exchange is completed it will be fully equipped with International apparatus, replacing equipment made in France.

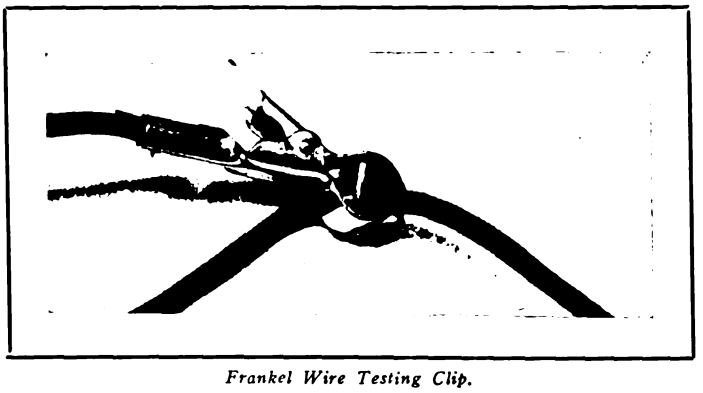
THE GRAY PAY STATION COMPANY, of Hartford, Conn., has issued an attractive and at the same time valuable brochure entitled "The Book of Public and Measured Telephone Service Equipment." The design is unique in that it represents a large volume handsomely bound in blue colored leather. The contents are devoted entirely to the advantages of the Gray pay stations, of which there are twenty-one different types, illustrated and described, together with seven styles of registers. This company has developed the design of pay stations to the highest point of efficiency and is prepared to furnish apparatus to fit any requirements. The company will be pleased to mail this booklet to all parties interested and to furnish any additional information desired respecting its devices for registering calls and coin collecting machines

Digitized by Google

of which it has made a specialty in designing for a number of years.

A CLIP FOR MAKING TEST CONNECTIONS.

PROBABLY every one has heard of the enterprising switchboard man who was making tests of insulated wire circuits. To save himself the trouble of scraping and cutting off the insulation he stuck a pin through the insulation of each wire, the wires from the testing instrument being fastened to the pin. He thus made a quick, though far from satisfactory, test connection. Ever since that attempt, a hundred geniuses have been working to devise some quick, sure means of making a test or temporary connection with insulated wire.



Frankel Wire Testing Clip.

One has at last been patented. It is pictured herewith, and so far as known, is the only thing of the kind on the market. The half-tone cut, made from a photograph of the "Frankel Wire Testing Clip," as it is known, shows in detail the method of making a test connection. The clip, it will be noticed, consists of a snap, similar to those sometimes found on suspenders, only the spring is much stronger. The clasping ends terminate in strong teeth, and it will be noticed there is a stout, sharp-pointed pin in the center. The teeth are designed to firmly grasp the wire while the pin pierces the insulation without damage and makes a good connection with the wire. The wire is left as sound and well protected as ever.

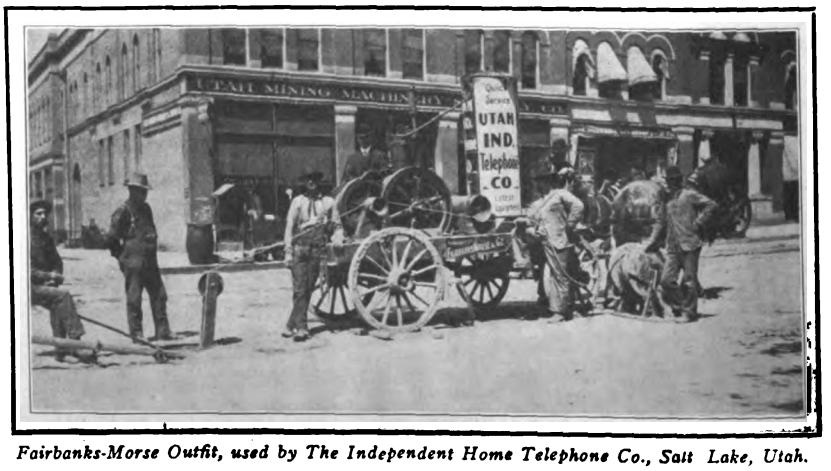
The clips are manufactured and sold by the Frankel Display Fixture Co., 718 Broadway, New York City, and already many of the largest exchanges, both Bell and Independent, are buying the clips in large quantities. The many re-orders received from such companies as the New York Telephone Company, Western Electric Company, United States Electrical Supply Co., Henderson Telephone and Telegraph Company, Henderson, Ky.; Chesapeake & Potomac Telephone Company, Baltimore, Md., and Washington, D. C.; Peninsular Telephone Company, Tampa, Fla., speak well for the practicability and utility of these clips. The Frankel Company on another page quotes prices of the clips, and offers to refund the money if a sample dozen or hundred purchased are unsatisfactory.

THE GUARANTEE TELEPHONE AND EQUIPMENT COMPANY, of Chicago, Ill., has removed from its former offices at 73-75 West Jackson Boulevard to 60-68 West Van Buren street. The company makes a specialty of re-equipping and remodeling second-hand telephones, switchboards and appliances, and putting them in first-class shape. Although it is second-hand, most of the apparatus the company sells is claimed to be just as good as new, and incidentally it is, of course, much cheaper. The company is now situated in commodious quarters and is finely equipped for handling all orders.

CABLE LAYING ENGINE.

THE cut herewith illustrates a device which affords quite a departure in the manner of laying cable. The apparatus consists of a 6 horse-power vertical gasoline engine, direct connected to a geared winding drum, actuated by a friction clutch. Both devices are mounted on one base. This makes a compact and self-contained machine, which is mounted on an ordinary platform wagon. This wagon carries a gasoline supply tank and a small water tank for cooling the engine, together with the necessary tools and apparatus used in cable laying. The operation of the machine is especially simple, after the engine is put in motion, by turning on the gasoline and pulling the engine over the dead center the engine is kept running continuously, and by means of a friction clutch operated by an end lever the winding drum can be started and stopped at the will of the operator. A small spool or nigger head is located on the outer end of the shaft carrying the winding drum. By means of these two drums it is possible to meet all of the requirements of fast and slow pulling, either for light or heavy loads.

This apparatus was recently installed by the Independent Telephone Co. at Salt Lake City, Utah, and while in that city a new world's record for laying telephone cable was established by the crew in charge. Under the direction of Chief Engineer Frank B. Hall, in 7 hours and 40 minutes, 14,719 feet of 200-pair cable were laid by a force of nine men. The best previous record was made in St. Louis in 1898 when nine men and a foreman stretched 7,556 feet of 120-pair cable in 8½ hours. Chief Engineer Hall expresses himself as believing that the above described machine is without doubt the best method of stretching cable yet discovered. The 6 horse-power Fairbanks-Morse combined vertical engine and winding gear is provided with a 16-inch drum and a 5-inch winch or nigger head. The wagon upon which the apparatus was mounted was constructed with a 3½-inch running gear, with a heavy bed made of best 6 x 8 Oregon pine. The engine is provided with a regulating device which is arranged so that it can be operated from either side of the running gear, and by means of which the engine speed can be controlled as desired. With a ½-inch wire rope fastened to the end of a large cable, and passed through the subway



Fairbanks-Morse Outfit, used by The Independent Home Telephone Co., Salt Lake, Utah.

FOR SALE

Advertisements under this head, $1.00 for 25 words or less for each insertion. Prepaid.

FOR SALE—Independent magneto plant in Southern town, 3,500 population; 200 drop switchboard; 150 drops in operation; gross annual income $3,500; fixed expense $1,300; in operation five years; no competition; town and plant growing fast; price, $10,000. Address Box 255, care AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 255

FOR SALE.—I have a telephone proposition which will interest any one of means who cares to investigate. This property is in fine condition; located in excellent field and paying. Write me at once. Box 270, care of AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 270

FOR SALE.—Telephone Exchange in town of 850. Equipped with Stromberg board; North Telephones; 65 local subscribers; 15 party lines; good connections. Further particulars given on request. Address Everton Telephone Co., Everton, Mo. 271

WANTED

Advertisements under this head, 25 cents for 25 words or less for each insertion. Prepaid.

WANTED—To meet an investor with capital with a view to developing an automatic telephone which can be made at one-third cost of present automatic systems, also other telephonic devices. Exceptional opportunity. No agents or promoters need apply. Apply Box 272, care AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 272

WANTED—A civil engineer. Must be a good draughtsman, methodical and accurate; familiar with cable and pole line construction and one who can handle men and meet the public in a congenial way. Position permanent; opportunity for advancement to the right man. Address L. W. STANTON, 411 Electric Building, Cleveland, Ohio. 275

WANTED—A first-class telephone electrician having had experience from bottom up; able to handle all troubles in exchanges, both inside and outside. Well up on toll line troubles. Write giving references, etc. THE SOLOMON VALLEY TEL. CO., Beloit, Kans. 274

AM open, any time between now and March 1, for position as superintendent or manager of exchange. Am, at present, managing a system built by me, but want larger field. Fifteen years' experience in all branches of telephone business. Would accept good position other than above mentioned. Best of references furnished. Address Box 268, AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 268

WANTED—Managers for two telephone plants of more than 1,000 telephones. Must have executive ability, a keen sense of modern business and be congenial in meeting the public. Address L. W. STANTON, 411 Electric Building, Cleveland, Ohio. 276

WANTED.—I am seeking a gilt-edged investment in some first-class telephone property. Not particular as to location, but must be shown before I buy. Address, Box 269, care of AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 269

WANTED—Position by manager. At present has charge of four exchanges, common battery and magneto. Has had factory experience, building and installing complete equipment. Understands handling of men and laying out complete installations. Have rebuilt exchanges and put them on paying bases. Will be open January 1st. Address Box 277, care of AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 277

to the engine, a pull of any distance can be made. As much work has been accomplished by the use of the above described apparatus in five minutes as would have been accomplished formerly by four men in two hours. It would appear that from the description and the records, that an apparatus of this kind would find great favor among many of our larger telephone companies. For details address the makers, Fairbanks, Morse & Co., Chicago, Ill.

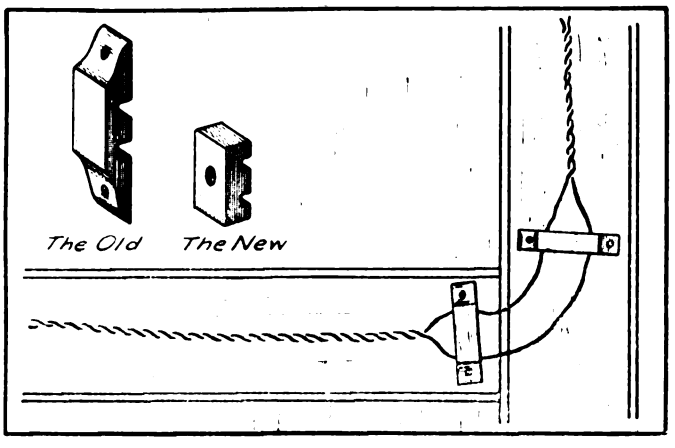

Fig. 1. Wiring With Wooden Cleats.

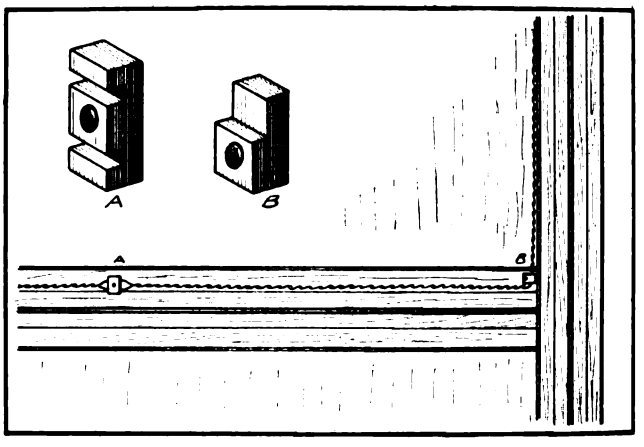

Fig. 2. Wiring With Hard Fibre Cleats.

A HARD FIBRE CLEAT.

THERE is an old adage, the moral of which is that it is the little things in this world that count most. One of these "little things" directly applicable to the telephone business has recently been called to the attention of telephone men. It is the "Morris Hard Fibre Cleat," manufactured by the Morris Electric Company, Fourth and Shipley streets, Wilmington, Delaware. In recent years no one specialty has probably been placed on the market that appeals to the up-to-date and economical telephone manager to such an extent as does this cleat. It was designed particularly to take the place of the clumsy and unsatisfactory wooden and porcelain cleats, and it has proven itself equal to the task.

In Figures 1 and 2, respectively, are shown drawings of inside wiring run with the old wooden or porcelain cleats, and the new Hard Fibre Cleat. Comment is unnecessary as to the results.

These fibre cleats possess many advantages. They are very much smaller than either wooden or porcelain cleats, which fact alone enables an ordinary installer to make a practically concealed job of wiring. The cleats being made of fibre are, of course, perfect insulators, and they will never break. This latter point will appeal to all managers that appreciate the importance of "saving the pennies." The prices for these cleats are no more than for ordinary porcelain and cheaper than wooden cleats.

They are made in three colors, red, gray and black, to harmonize with different styles of woodwork and interiors. Several styles are made: for corners, two wires, twisted pairs and three wires. Already many of the largest Bell and Independent exchanges have adopted these fibre cleats as standard.

Samples and particulars may be had by addressing The Morris Electric Company, Fourth and Shipley streets, Wilmington, Del.

THE CENTURY TEL. CONS. Co. has received an order from the Northwestern Tel. & Teleg. Co. for a local and toll switchboard for its Carthage exchange, which will make four switchboards furnished this company within a month.

A NEW BRACKET TELEPHONE.

ILLUSTRATED on this page is the "Skelleyphone," a new device intended to "lighten the white man's burden." The Skelley Mfg. Co., 50 High street, Cleveland, Ohio, in announcing the "Skelleyphone," states that it is "trial worthy," and that it is "an extension arm telephone that saves time, trouble and temper." We all know that such a device interests the up-to-date manager. The "Skelleyphone," as illustrated, consists of a receiver, transmitter and hook switch, mounted in the usual way on an upright stand. This stand is similar to the ordinary desk stand, with the exception that the base is removed. The upright is then fastened to a double swinging arm. This arm may be attached to either a roll or flat top desk, table, stand, or the wall.

Parts of the "Skelleyphone."

All of the working parts of the "Skelleyphone" are so constructed that by the loosening of one screw all inside parts are readily accessible. The opening of this screw brings before the troubleman or inspector every part of the telephone, so that he can readily see that all springs are making contact, that all wires are in good condition, and that all cord connections are securely fastened and under their proper binding posts.

By means of a special fastener formed in the fiber base block the receiver and pedestal cords are held in position, so that no pull or jerk can in any way affect their contact connections.

The swinging arm used on the "Skelleyphone," to always insure that the telephone is at hand ready for use, yet never in the way, is the same as the desk-set bracket made by the Skelley Mfg. Co. One of the novel features of these brackets is that they are made

The Morris Hard Fibre Cleats

One customer says: "They are worth their weight in gold."

Another: "They save half the time of my men."

Still another says: "They give inside wiring effects that harmonize with the most beautiful interiors."

And yet another: "That he figured the *cleats had cost* him *nothing,* because they had done away with the item of replacement that figures heavily with breakable wooden and porcelain cleats."

Perfect insulators. Never break or split. Smaller and neater and cheaper than any other. *If you have not seen them write to-day for free samples.* Made in three colors, red, gray, black. Specify color, otherwise we will send red.

"Style A." (Exact Size.)

to hold two telephones. This will be appreciated by patrons of two telephone companies, or in offices that have an intercommunicating system in addition to the regular telephone service. Either telephone may be lifted from this double bracket without unfastening any screws, and the telephones may be swung in any direction without entangling the cords. As a proof of the recognized superiority of the Skelley bracket telephone the following letter has been received from O. F. French, general manager of the Cuyahoga Telephone Company, of Cleveland:

> "GENTLEMEN:—Since we have introduced your so-called 'bracket' desk telephone, the demand for them has been rapidly increasing.
>
> "In my mind this type of telephone is more convenient for a business man's desk than any other in the market today. We are also very well pleased with the workmanship of the instrument, the maintenance of same being very low. Your extension arm bracket, of which we have several hundred in use, is deserving of widespread use. In this bracket grace of outline and strength are so combined as to produce a most satisfactory bracket."

The Skelley Mfg. Co. will be glad to furnish full particulars and prices on any of its apparatus, and will send its catalogue on request. Further particulars and illustrations will be found in its advertisement in this issue.

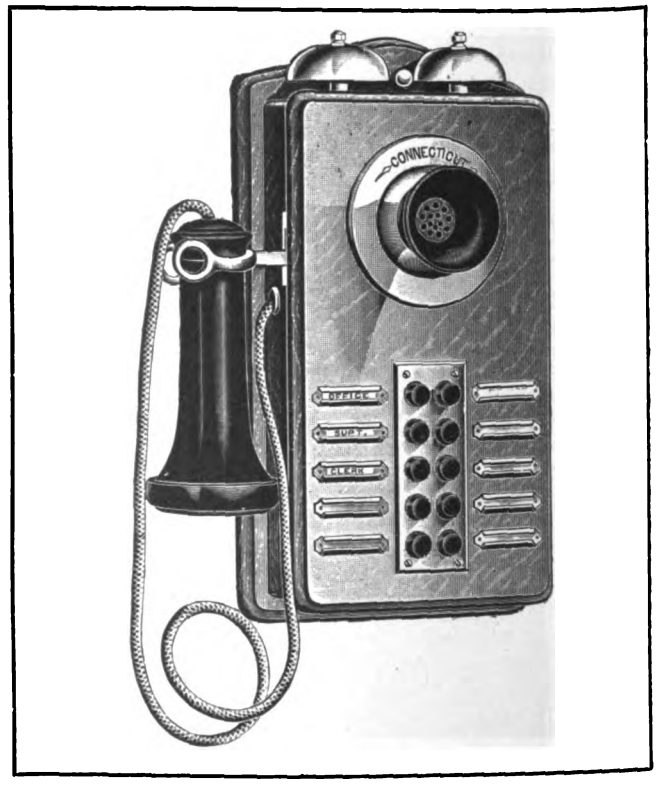
FRANK B. COOK, 240 West Lake street, Chicago, Ill., is conducting experiments at Lewis Institute on new protective devices, which he says will practically revolutionize the present system, as they are along entirely new and different lines.

G. M. GEST, the expert subway contractor of New York and Cincinnati, has been awarded by the jurors at the St. Louis Fair the highest award for conduit construction.

NEW AUTOMATIC BRANCH EXCHANGE TELEPHONE.

THE Connecticut Telephone and Electric Company, of Meriden, Conn., realizing the increasing possibilities of branch exchange equipments for business houses, etc., have brought out an automatic system which is designed for branch office exchange work in connection with both magneto and common battery city service. While the branch exchange has come into more general use in the past two years, it is still an acknowledged fact that the rental of the ordinary switchboard and telephone instruments is far above the means of the average business house. Again there is the continual expense of an operator. The instrument shown is automatic, that is, each party makes his own connections.

A party wanting any other department of a factory or offices has simply to push down the button corresponding to the department wanted. The pushing down of this button automatically cuts in the party and calls; when the conversation is finished and the receiver is returned to the hook the party called is automatically cut off the line. This system is particularly well designed for connection to common battery city service. No. 1 button can be designated as the exchange button throughout the system if outside service is desired. To call central you have simply to press down the exchange button and remove the receiver in the regular way, thus making the light burn at central. When conversation is finished the button is automatically reset to its former position, thus you have intercommunication between any department or offices in the building in which this exchange is installed, as well as automatic and city exchange connection from any point without the expense of a central operator and switchboard. The construction of this instrument is very simple. All connections are made on hard rubber and the transmitter, receiver and working parts are of the very best design. The switching device is built to stand heavy use and all kinds of heat and cold conditions. The trip is of case hardened steel and there is no possible chance for wear. For this as well as in the branch switchboards one or two trunk lines extending to the central office is amply sufficient to take care of all outside traffic. Owing to the simplicity and low cost of this automatic system it will evidently,



Connecticut Automatic Telephone.

to a large extent replace the old switchboard equipments for branch exchanges in buildings. This system can be installed at an exceedingly moderate price and the annual expense to the subscriber should be very much decreased as the operating expense and the cost of the installation to the telephone company is certainly greatly diminished over the switchboard equipment. The very reasonable cost of maintenance of this system will enable hospitals, business houses, residences, etc., to install it, thereby greatly increasing the revenue to the telephone company, and thereby securing a trade which heretofore could not be reached. Full information will be furnished by the Connecticut Company on request.

THE MEDORA MILLING COMPANY, Medora, Ill., is distributing some blotters which, besides being of value to the office force, draw the attention of managers to its stock of chestnut poles. This company is in an exceptional position to furnish any quantity of poles of any desired size at a moment's notice and will be pleased to correspond with any parties desiring information.

MR. MANAGER:

Do you ever wonder how you can handle Rural Lines so as to give Subscribers satisfaction at a profit to the Company?

Do you realize that to give Rural Subscribers satisfaction you must, *first of all*, have "Central" answer their first call instantly.

Do you think you cannot do this unless at an increased operating expense?

You can handle more of these lines, by using

The T. & A. Selective "Central" Relay

with the operators you have and give incomparably better service.

Our system is for either Ground Lines, Straight Metallic or "Divided Circuit" Metallic Lines.

You do not have to Purchase New Telephones

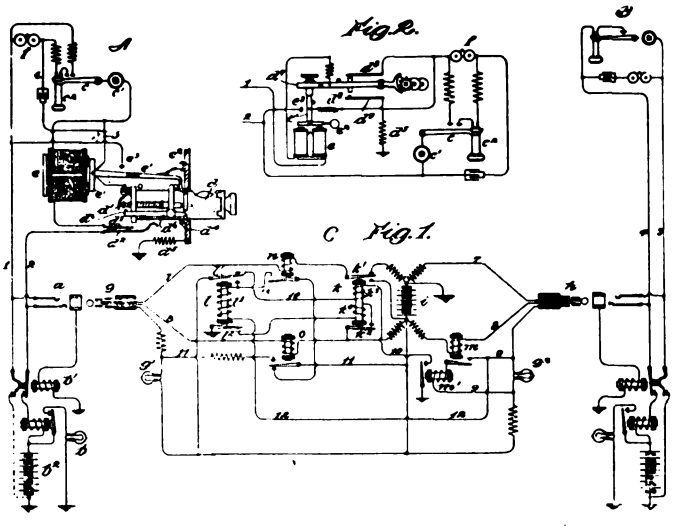
TELEPHONE PATENTS

IMPROVED TELEPHONE TOLL LINE SYSTEM.

W. W. Dean, of Chicago, Ill., patents (No. 771,972) an improved telephone toll line system, and assigns to the Western Electric Company. The object of this invention is to provide a toll line device consisting of a coin receiving box in which the subscriber must deposit a coin in order to connect with the central office, and a register for recording each connection. The circuit of the system is shown in the accompanying illustration. Its operation is as follows: The subscriber signals by depositing



a coin in the coin receiver *d*. This closes the circuit of limb *2* to ground, at *d'* through magnet *e*. Current from *b2* through line relay over limb *2* through magnet *e* to its armature and contact spring *d'* to plunger coin receiver thence to ground, exciting line relay and signaling the office. The direction of the current is such that the armature of the polarized magnet is not moved. When the operator answers, the subscriber gives his order in the usual manner. In removing his receiver he has closed a bridge over the line in the usual manner, the contact *e3* being opened and the contacts *d2* and *d3* closed. The magnet *e* is unaffected by the substitution of the battery *i* for the battery *b2* since the polarities are the same. The supervisory signals *n* and *o* are excited by the current over the conductor *7* to limb *l* through the substation and magnet *e* back over limb *2* and conductor *8* to the negative side of the battery. When subscriber at *B* answers, he bridges conductors *3* and *4*, closing circuit through supervisory relay *m'*. This relay in drawing up its armature, closes a circuit to ground from the free pole of the battery *i*. This circuit including armature *l'* and back contact of relay *l*, conductor *10*, and magnet *K3* of switch *k*. Current in the winding *k3* attracts the armatures *k'* and *k2*. The armature *k'* transfers connection from conductor *7* to the free pole of the battery *i*, armature *k2* completes path to ground from side *8* of plug circuit, including the retaining winding *k4*, controlled by armature *l2* of relay *l*. Current flowing through winding *k4* keeps magnet excited. The operation of the electromagnet switch *k* reverses the current through magnet *e* and prevents the use of the telephone till the subscriber operates the toll device.

As conductor *7* is connected with free pole of battery *i*, the circuit is over limb *1*, through magnet *e*, conductor *2*, spring jack conductor *8*, relay *o*, to point where armature *k2* is tapped on, thence through winding *k* to ground by armature *12*; also from battery *i* through one winding of the repeating coil to armature *k2*, but enough current flows through the substation to operate relay *e*.

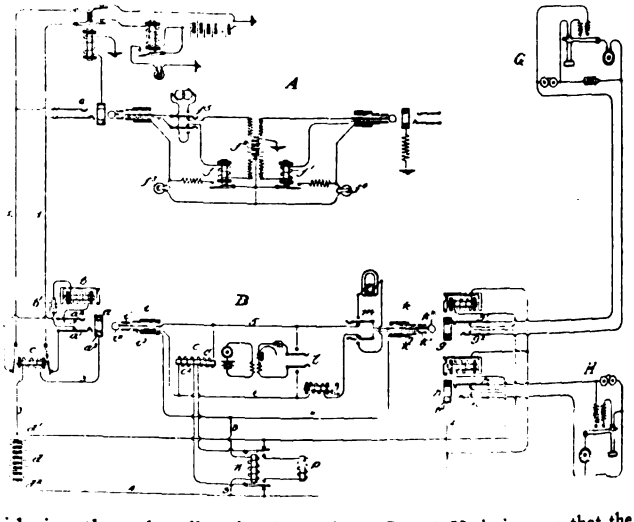
It will be noted that the current through *e* has been reversed. The armature *e'* will swing counter-clockwise and close contact *c3*, short-circuiting the telephone, display signaling *c2* and removing the obstruction from the coin receiver *d* so that it may be operated. The calling subscriber will then push the button, depositing the coin in the box and may proceed with his connection.

ANTISEPTIC APPLIANCES.

H. L. Cutter, Los Angeles, Cal., patents (No. 771,128) a hygienic attachment for telephone transmitters. The object of this invention is to provide an improved hygienic mechanism for telephone transmitters. This is accomplished by means of a small light frame-work that supports a roller carrying a strip of sterilized paper. The frame-work is secured to the transmitter by being clamped in the rubber mouthpiece in such a manner as to enable the strip of paper to be drawn in front of the mouthpiece. As fast as the paper is used it may be torn off and renewed.

PRIVATE BRANCH EXCHANGE SYSTEM.

J. L. McQuarrie, of Chicago, Ill., patents (No. 772,900) an improved private branch exchange system and assigns to the Western Electric Company. The object of this invention is to provide a circuit for private branch exchanges which are operated upon the common battery plan so arranged that those subscribers who are authorized to obtain regular exchange service can do so while the private exchange subscribers can only talk among themselves. The circuit of this invention is shown in the accompanying diagram, in which the central office is shown at *A*, the private branch exchange at *B*, and two subscribers at *G* and *H*. The trunk line which extends between the private branch exchange and the central office is indicated by *1 2* and terminates in the private branch exchange in the line springs *a' a2*, including a signal *b*, the circuit of which is opened by a condenser. The continuity of the trunk line conductors *1 2* is controlled by the blocking relay *c*. Normally the armatures of this relay maintain the continuity of the trunk line, but the winding of this relay is included in a local circuit from the ring of the jack *a3*. Con-



sidering the subscribers' sub stations *G* and *H*, it is seen that the sub station *G* has no third wire to the ring of its jack, while the sub station *H* has, hence when the plug *k* is inserted in the jack *h* of the subscriber *H*, current flows through the conductor *3* of blocking relay *c* and opens the trunk line, consequently subscriber's line is open and he cannot talk to the main exchange, but in the case of subscriber *G* there is no battery connection from the ring of the jack, consequently these subscribers can converse among themselves and obtain exchange service as well.

THE WEEK'S MESSAGES

FINANCIAL.

MARSHALL, MICH.—The Marshall Telephone Company has increased its capital stock from $15,000 to $50,000.

CLEVELAND, OHIO.—The United States Telephone Company has filed a trust deed in favor of the Cleveland Trust Company, covering a mortgage for $1,000,000 5 per cent. gold bonds.

ELLSWORTH, WIS.—The Pierce County Telephone Co., of Ellsworth, by its president, F. M. White, and secretary, W. H. Currier, has caused its capital stock to be increased from $10,000 to $30,000.

FRANCHISES.

MANITOU, COLO.—An ordinance granting a telephone franchise to H. C. Kinsman and M. H. Spere, of Colorado City, has been introduced and is under consideration.

DALTON, GA.—The Union Development Company has made an application for a charter in Whitfield County to operate a telephone system.

AVERYVILLE, ILL.—The Interstate Independent Telephone and Telegraph Company, of Peoria, has applied for franchise in this town.

SKOWHEGAN, ME.—The Central Maine Telephone Company has applied for a franchise to enter this village.

LACONIA, N. H.—The Citizens' Telephone Company, of Laconia, is extending its system to Alton Bay and will ask for a franchise in Farmington.

BURBANK, S. D.—T. S. Maude, of Burbank, has applied to the county commissioners for a franchise to operate and construct a telephone line through Union County from Burbank to Spink.

DALLAS, TEX.—F. B. McElroy, who for some time has been endeavoring to secure an Independent telephone franchise in Dallas, has stated that he would contribute the funds necessary for holding a special election to decide whether the voters of this city desire an Independent telephone system. If the voters should decide favorably, there is very little doubt that the council would grant such a franchise.

CARMEL, WEST VA.—The Carmel Telephone Company has made application to the town council for a franchise to construct and operate a system in that place.

ELECTIONS.

RUSHVILLE, IND.—At the recent annual meeting of the Rushville Co-operative Telephone Company, the following directors were elected: H. E. Barrett, W. D. Root, B. L. McFarlan, T. M. Green. The secretary's report shows receipts for the year in excess of $15,000, with disbursements of $14,664, the balance being $440.13.

CLEVELAND, OHIO.—The directors of the Federal Telephone Company, at a recent meeting, re-elected all the old officers for the ensuing year, as follows: F. S. Dickson, president; E. W. Moore, vice-president; James B. Hoge, second vice-president and secretary; R. W. Judd, treasurer.

CHARLESTON, OHIO.—F. L. Beam and Cyrus Huling have been elected directors of the Home Telephone Company, of Charleston.

GENEVA, OHIO.—The Madison Telephone Company at its annual election re-elected President Charles De Veau and the other officers.

CHARLOTTEVILLE, VA.—At the annual meeting of the Albemarle Telephone Company, the following officers were elected: T. W. Twyman, president; J. B. Andrews, vice-president.

COMBINATIONS.

FLORA, IND.—The stockholders of the Flora Co-operative Telephone Association have voted to purchase the John Q. Miller Telephone Plant, which has been in operation in Flora for some time, thus forming a consolidation of the two telephone systems which have been operated in Flora.

SAYBROOK, ILL.—Robert Means has purchased the Saybrook Telephone Exchange, and Howard Means, his son, will take possession. The new company will be known as H. R. Means & Co.

FAIRBURY, NEB.—C. W. Bartlett has purchased an interest in the Fairbury Telephone Company and has taken charge of the exchange.

LYONS, N. Y.—It is rumored that the Wayne Telephone Company, of which the Lyons Telephone Company is a branch, will consolidate with the Wayne-Monroe Telephone Company.

NEW COMPANY NOTES.

SELMA, ALA.—The Mapleville & Selma Telephone Company has been incorporated with a capital stock of $4,000. The incorporators are: N. H. Ryder, L. C. Elebash, E. E. Todd, T. M. Crumton, E. G. Ensign, W. C. Dyer.

SANTAMONICA, CAL.—The Home Telephone & Telegraph Company, of Santamonica and Ocean Park, has been incorporated with a capital stock of $250,000.

COLORADO CITY, COLO.—The El Paso Telephone Company has been established with a capitalization of $500,000, for the purpose of building a telephone system through the counties of El Paso, Teller, Fremont, Pueblo, Douglas and Denver. The principal organizers of the company are: M. H. Spere, N. B. Hames, C. D. Taylor.

MANSFIELD, ILL.—The Mansfield Mutual Telephone Company has been incorporated and a plant will be built in Mansfield and vicinity, operating 200 telephones. The following officers have been elected: Howard Nash, president and secretary; W. H. Burns, treasurer; and John Churchill, Samuel Howe and Charles Gordon, directors.

CLARE, IA.—The Farmers' Mutual Telephone Association, of Clare, has been organized by W. S. Lyons, Gust. Baumchen, J. M. Hood, J. J. Condon and Henry Haulwick, of West Jackson, and D. S. Cougholn, G. C. Voigts, P. H. Cain, Bert Schuster, J. McElroy and J. D. Hood, of Deer Creek.

CLINTON, IA.—The Twin City Telephone Company has been incorporated with a capital stock of $600,000.

DUNKERTON, IA.—The Blakeville Farmers' National Telephone Company, of Dunkerton, Black Hawk County, Ia., has been incorporated with a capital of $5,000. The officers are: President, C. W. Smith; vice-president, Martin Rinderknecht; secretary, William Rodger; treasurer, Sidney Weick.

JEFFERSON, IOWA.—The Star Telephone Company has been incorporated to build a telephone line. B. Curtis is president and J. S. Neil treasurer.

ROCKWELL, IOWA.—The Rockwell Telephone Company has been incorporated with a capital stock of $25,000 by E. N. Egge and others.

PEKIN, KANS.—The Pekin Telephone Company has been incorporated with a capital stock of $4500.

ELLSWORTH, ME.—The Union River Telephone Company has been incorporated to build telephone lines in Hancock County. Albert E. Mace, of Aurora, is president and general manager, and Dr. J. H. Patten, of Amherst, secretary; T. Silsby, of Amherst, treasurer.

NEWTON, MICH.—The Newton & Le Roy Telephone Company has been organized to build telephone lines in these townships. The principal stockholders are E. C. Cory, J. A. Herd, Henry Randt and others.

GOOD THUNDER, MINN.—The Pride Telephone Company has been organized and will construct a line into Good Thunder.

ARCHER, NEB.—The Archer Telephone Co. has been incorporated with a capital stock of $50,000 to construct and operate a telephone system in this village. The directors are A. J. Harshberger, J. B. Templin, Wm. Johnston, H. G. Mithofer and F. F. Wagner.

CORTLAND, N. Y.—The Otsetlic Valley Telephone Company has been incorporated with a capital stock of $4,000. The directors are: W. J. Wildman, E. T. Potter, P. C. Wheeler, J. M. Lotridge, M. L. Halbert, A. Fowlston and J. H. Murray.

JOHNSONVILLE, N. Y.—The Johnsonville Telephone Company has been incorporated with a capital stock of $500 by J. D. Van Wert, G. I. Hanna and E. H. Abbott, all of Johnsonville.

WINDSOR, N. Y.—The Lester Telephone Company has been incorporated with a capital stock of $2,000 by Wilber Brink, Levi Uresson and J. E. Kent, of Windsor.

UTICA, N. Y.—Sholes, Ferris & Foley are drawing articles of incorporation of the Independent Telephone Securities Company, which will have headquarters in Utica. The company will have a capital stock of $800,000 and an authorized bond issue of $15,000,000. The directors are as follows: Thomas W. Finacune, of Rochester; Frederick W. Zoller, secretary of the Union Trust Company of Rochester; George R. Fuller, manager of the Rochester Telephone Company; Charles H. Poole and T. Harvey Ferris, of Utica.

CHESTER HILL, O.—The Chester Hill-Brown's Mill Telephone Company has been incorporated with a capital stock of $3,000. The incorporators are Fred McInturf, E. Hopkins, H. S. Hopkins, J. M. Russell, T. J. Edgerton.

COLUMBUS, O.—The New Lebanon Telephone Company, of Montgomery County, has been incorporated with a capital stock of $10,000.

MARIETTA, OHIO.—The Barlow & Watertown Telephone Company has been incorporated with a capital stock of $10,000 by S. W. Harvey, R. Wolcott, H. Fisher, L. A. Fisher and J. Fisher to operate telephone lines in Washington and Morgan Counties.

NEW LEBANON, OHIO.—The New Lebanon Telephone Company has been incorporated with a capital stock of $10,000 by D. C. Mills, V. E. Weaver, G. C. Smith, G. W. Hepner and S. P. Dihl.

INDEPENDENCE, ORE.—The Independence Telephone Company has been incorporated with a capital stock of $500 by Dr. O. D. Butler, W. A. Messner and J. R. Craven. The company will build a line to Monmouth and will connect with the Louisville, Airlie, Fall City and Dallas lines. A central office will be installed here.

PERRYSVILLE, PA.—The Perrysville Telephone Company has been organized to build a telephone line between Genesee, New York, and West Bingham, Pennsylvania.

PLAIN GROVE, PA.—The Plain Grove Telephone Company is being organized with a capital stock of $5,000 by J. B. Humphrey, N. A. Offutt, W. J. Offutt, M. W. Keener and W. B. Rodgers.

LEXINGTON, S. C.—The Citizens' Telephone Company, of Lexington, has been incorporated with a capital stock of $1,000 by J. E. Coughman and A. J. Fox.

BROWNWOOD, TEX.—The West Texas Telephone Company has been incorporated with a capital stock of $100,000 by C. C. Woodworth, J. A. Walker and others, of Brownwood.

BEDFORD, VA.—The Southside Rural Telephone Company has been organized with a capital stock of $10,000. A. J. Gillaspie, president; Dr. S. H. Price, vice-president; H. Pollard, general manager, and J. M. Speece, secretary and treasurer.

WAITSBURG, WASH.—The Waitsburg Rural Telephone Company has been organized with the following officers: J. W. Morgan, president; Gus Vollmer, vice-president; W. B. Brooke, secretary; A. W. Phillips, treasurer; E. M. Denton, Walter Price and Frank Jonas, trustees.

BLAINE, WIS.—St. Croix Farmers' Mutual Telephone Company, of Blaine, has been incorporated with a capital stock of $3,000. The incor-

porators are C. H. Chipman, H. B. Dunn, L. T. Fournier, J. V. Carter and Richard Goldschmidt.

PERSONAL.

L. BARNES has severed his connection with the Southern Bell Telephone Co., at Columbus, Ga., and gone with the Automatic Telephone Company, of Columbus.

W. T. BELT has been promoted to the position of superintendent for the Nebraska Telephone Co., in Nebraska, South Dakota and Western Iowa.

J. R. CARTER has been appointed manager for the Nebraska Telephone Co. in South Omaha.

MISCELLANEOUS.

WILMINGTON, DEL.—The Delmarvia Telephone Company will install an automatic switchboard which will have an ultimate capacity of 10,000 lines.

JACKSONVILLE, FLA.—The Independent telephone plant has been sold to D. T. Gerow.

TIFTON, GA.—The exchange of the Tifton Telephone Company was recently severely damaged by fire.

CRAWFORDSVILLE, IND.—The Home Telephone Company has issued a new telephone directory, containing 1,600 subscribers and 1,100 toll connections.

PEKIN, ILL.—The New Independent Telephone Company is completing the work prescribed by the city council and had returned to it the $20,000 forfeit which the company had put up.

CALAIS, ME.—Forest City Telephone & Telegraph Company has effected a working agreement with the West Isles Telephone Company, of Deer Island.

WESTBROOK, ME.—The Northeastern Telephone Company has applied for pole and conduit privileges in this city.

GREENFIELD, MASS.—The Heath Telephone Company has established a toll station in this city.

SPRINGFIELD, MASS.—The Heath Telephone Company has rejected the proposition of the New England Telephone Company, whereby it was to abandon Shelburne Falls and replace its transmitters and receivers with those of the New England Company.

BATTLE CREEK, MICH.—The Citizens' Telephone Company has installed its new automatic switchboard, which is equipped for 1,000 telephones. A complete test has been made of every part of the apparatus, and the company has established a trouble department consisting of five men who have received a thorough training at the hands of experts from the Automatic Electric Telephone Switchboard Company, of Chicago.

GLENCOE, MINN.—The Norwood Young America and Cologne Telephone Company is now in full operation.

SHELTON, NEB.—At a meeting of the representatives of the Independent companies of Central Nebraska, the Central Nebraska Toll Association was organized. Fourteen Independent companies were represented, having a total of 6,000 telephones, and operating nearly 500 miles of lines. The companies represented operate in Hamilton, Hall, Buffalo, Custer, Dorson, Phelps, Adams and Furnas counties.

MULLICA HILL, N. J.—The Rural Telephone Company will open its line for business in the near future.

HANNAFORD, N. D.—Twenty-seven subscribers have been secured for the local telephone exchange.

OAKLAND, ORE.—The Oakland Development League is considering the matter of installing a local telephone system. Hon. A. F. Stearns is interested in the matter.

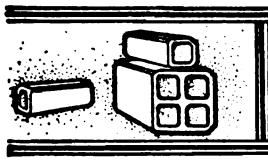
KENOSHA, WIS.—The Citizens Telephone Company is about to issue a joint directory which will contain the names of subscribers in Kenosha, Racine, Bristol, Pleasant Prarie, Somers, Winthrop Harbor and connecting lines.

UNDERGROUND.

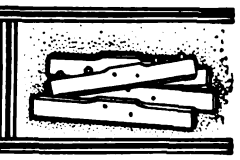
LOS ANGELES, CAL.—The Home Telephone Company is extending its underground system in this city.

ST. PAUL, MINN.—The Twin City Telephone Company has taken out a permit for underground conduits on certain streets.

AUBURN, N. Y.—The street department has cut many of the lines of the Automatic Telephone Company, which were overhead in the underground district of the city. The company will now have to place its lines in that section in underground conduits.



New Construction in the Field



HUNTERSVILLE, ALA.—The Huntersville Telephone Company is going to install a new switchboard.

RIVERSIDE, CAL.—The long distance line from Riverside to Los Angeles and other California cities, will be completed within the near future.

LODA, ILL.—J. E. Fitzsimmons is building a farm telephone line for W. C. Gress, of Loda.

PEORIA, ILL.—The Interstate Telephone Company is making arrangements to construct lines to Matteson, and install an exchange at that place.

COLUMBUS, IND.—The New Long Distance Telephone Company is preparing to build a line between this city and Hope.

CRAWFORDSVILLE, IND.—The new metallic long distance circuit from this city to Indianapolis has been completed. There are now three lines connecting this city with Indianapolis and other long-distance points.

MONROE, IND.—Dr. F. M. Parish is building a line to Steele and will also construct a line south from this village.

MARSHALLTOWN, IA.—The Kiron Telephone Company has extended a line into Boyn.

BRAZILTON, KANSAS.—The Hepler Mutual Telephone Company is extending its system to Walnut, and from Farlington to Gerrard. Lines will be built from Walnut to St. Paul and from Brazilton to Farlington.

NEWBURG, ME.—The Unity Telephone Company is extending its system in this vicinity.

COOLEYVILLE, MASS.—The Highland Telephone Company is extending its system to Locks Village and Wendell.

BATTLE CREEK, MICH.—The Citizens' Telephone Company has decided to extend its lines to Manwataka, Boon and Henrietta, in Wexford county, and it is expected that the company will be in operation in the three villages by the beginning of next year.

HART, MICH.—The stringing of the second copper wire between Muskegon and Hart has been completed. Work was begun last spring by the Citizens' Telephone Company, of Muskegon, and carried as far as White Hall by that company. The remainder of the distance has been finished by the Lake Shore Telephone Company, of Oceana county.

MILFORD, MICH.—The extension of the Milford Rural, west from McCullough's, has been completed, and work has started on a line north to the Highland road connecting with a number of rural telephones. Other contracts are also being made at a satisfactory rate, and the telephone system is being developed rpidly.

BRAHAM, MINN.—The Maple Leaf Telephone Company has completed a line running from Stanchfield through Elm Park.

GAYLORD, MINN.—A new line has been built by the Nicollet County Telephone Company extending into Lafayette township of Nicollet county and connects with the Lafayette exchange. The line just complete will be known as the Swan Lake line.

LE SUEUR CENTER, MINN.—Work will soon be commenced on the construction of the Cleveland telephone line.

PERHAM, MINN.—The telephone line has been completed to Dent.

REDWING, MINN.—Headquarters have been chosen for the new telephone company, of which D. M. Neil is the local manager. Arrangements have been about completed for the construction of the plant.

ANOKA, NEB.—The Farm & Home Telephone Company has completed its line into Anoka, and has established a toll office. The company expects to extend its lines to Baker some time in the near future.

HUMBOLDT, NEB.—The Humboldt Telephone Company is laying cables to accommodate rural patrons.

PLATTSMOUTH, NEB.—The Plattsmouth Telephone Company is extending its system at Greenwood.

TILTON, N. H.—The Citizens' Telephone Company is stringing new lines and putting in many new telephones at Northfield Center.

CHESTER, N. J.—The Chester Telephone Company is making arrangements to extend lines to Bartley, Flanders, Parker and Pottersville.

CHATHAM, N. Y.—The Chatham & Canaan Telephone Company is preparing to build additional lines in this vicinity.

HAMDEN, N. Y.—The Launt Hollow Telephone Company is extending a new line to Walton. It has been planned to extend the line in the spring from Walton to Rock Raft, where it will connect with the Cannonsville-Deposit line. The company at present has its headquarters in Hamden, but it is likely that the main office will be moved to Delhi in the spring. Ralph Anderson, of Hamden, is president of the company.

JOHNSBURG, N. Y.—Preparations are being made to extend the telephone system from this village to Luzerne. A long distance line will be installed and a local line with exchanges at Thurman and Stoney Creek.

MT. MORRIS, N. Y.—The Nunda Telephone Company is extending its line to this village.

ST. JOHNSVILLE, N. Y.—A long distance line from the East has been connected with the Interstate office in this city.

STAMFORD, N. Y.—A new telephone line is to be built between Jefferson and Stamford via Churchills.

WATERLOO, N. Y.—The Empire State Telephone & Telegraph Company is extending its lines in this village.

CHARLESTON, OHIO.—Frank L. Beam, general manager of the Columbus Citizens' Telephone Company, and Cyrus Huling, have been elected directors of the Home Telephone Company of Charleston. Their election is said to indicate a complete reorganization of the company, and an extension of its lines.

DUBLIN, OHIO.—The Citizens' Telephone Company is erecting a new building here, and will install a new switchboard.

ALTOONA, PA.—The United Telephone Company is constructing a line between Martinsburg and Roaring Springs.

BLOOMSBURG, PA.—W. W. Fagley, division manager of the United Telephone & Telegraph Company, with headquarters at Bloomsburg, is arranging for the construction of lines into Foundryville. A pay station will be installed for the present, but it is likely an exchange will be located at Foundryville in the near future.

CHESTER, PA.—The United Telephone Company is extending its aerial cable system in this city.

HOLLENBACK, PA.—The Hollenback Telephone Company will build a number of lines in the near future. M. W. Bittenbender is president and C. H. Harter, secretary and manager.

STROUDSBURG, PA.—The Stroudsburg & Bushkill Telephone Company has surveyed a route to Portland, and will extend its lines to that place, connecting there with the Slate Belt Company's system.

HUDSON, S. D.—The Hudson Telephone Company will extend a branch line across the State line into Iowa.

PIERRE, S. D.—Work has been commenced on the Cheyenne River reservation. Two lines are to be built, one from White Horse Camp and the other from Cherry Creek.

OGDEN, UTAH.—The Utah Independent Telephone Company is running an additional circuit between this town and Salt Lake City.

Bituminized Fiber Conduit
For Underground Construction

Combines the **good features** of other conduits. **Eliminates** the **bad features** existing in many kinds. **Has valuable features** not found in any other ducts. :: ::
Made in 7-foot lengths with male and female joints, making construction very rapid and simple, with consequent low cost. :: :: ::
Alignment is perfect and permanent without tedious care and skill required in laying of butt-joint conduits. Users are astonished by the ease and rapidity with which cables can be drawn in, and this without the slightest scratching or injury to the lead covering thereof. Made in sizes from 1-inch to 10-inch diameter. ::
Bends of any radius and any angle. :: ::
Write us for further information and prices, stating sizes and quantities required. :: :: ::

The 1900 Dry Battery

THE most needed quality is reliability. No one wants a battery that will respond all right for a week or ten days then "suddenly go out of business." Another requirement is that it shall continue "strong" during its life. These two requirements besides many others are characteristics of

1900 BATTERIES

We guarantee them not to freeze, leak or break; we warrant them to work with a strong, steady current during their life (anywhere from six to eighteen months).

They are compact, always ready. They are better than wet batteries—no slop, no repairs, no breakage. Any one can replace a worn out one at a moment's notice. They can be carried anywhere—always ready for instant use.

Write us for our Complete List of Batteries and Telephone Supplies

THE AMERICAN TELEPHONE JOURNAL

Our Readers' Attention

is called to the editorial in this issue. The Editor has endeavored to present clearly the policy, past and present, of this paper—a policy always dictated by his clientele.

And he also presents another letter commenting on the new department:

> "'In the Manufacturing Field' is very interesting. It keeps one up to date in new ideas in the manufacturing line. I think it is a valued addition to your paper.'
>
> GEORGE L. SMITH,
> 4752 Prairie Avenue, Chicago, Ill.

The Editor gratefully acknowledges the many expressions of satisfaction with this department from subscribers, and would like to hear from every reader.

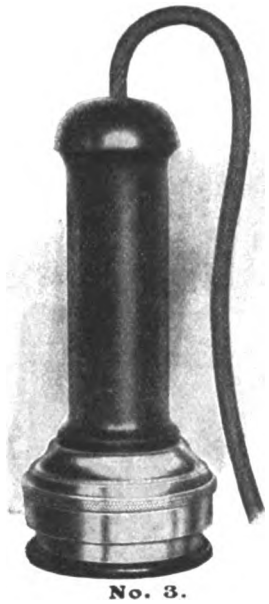
STROMBERG-CARLSON
TELEPHONE RECEIVERS



No. 3.

are made in two styles as illustrated.

We give the purchaser his choice of either type at the same price. We have been building the No. 3 type ever since we began doing business. The many thousands in use are a fitting testimonial to

Stromberg-Carlson Quality.

The No. 6 is just as good as the No. 3. That's all the recommendation it needs. Practically the same adjustment feature is embodied in both receivers, and both

No. 6.

ARE STANDARD.

Consider This Fact. We manufacture receivers by the thousands, every month, and use the most modern labor-saving machinery.

Is It Reasonable

to suppose any manufacturer can sell you a receiver *just as good as ours* at a price from 25 to 50% cheaper?

The argument just as good as a Stromberg-Carlson has helped to sell many receivers. Thousands of users have proven to their entire satisfaction that there are none *just as good.*

We are always glad to mail printed matter.

MORGAN & WRIGHT TAPE IS GOOD TAPE

Possesses exceptional adhesive qualities.
Will not dry out.
Unrolls smoothly and easily.
Has uniform insulation.
Is peculiarly free from pinholes.
Has high insulation resistance.
Is capable of withstanding extreme heat much longer than is required by the most severe tests.
Possesses an uncommonly high percentage of insulation composition.

Samples and prices furnished on request.

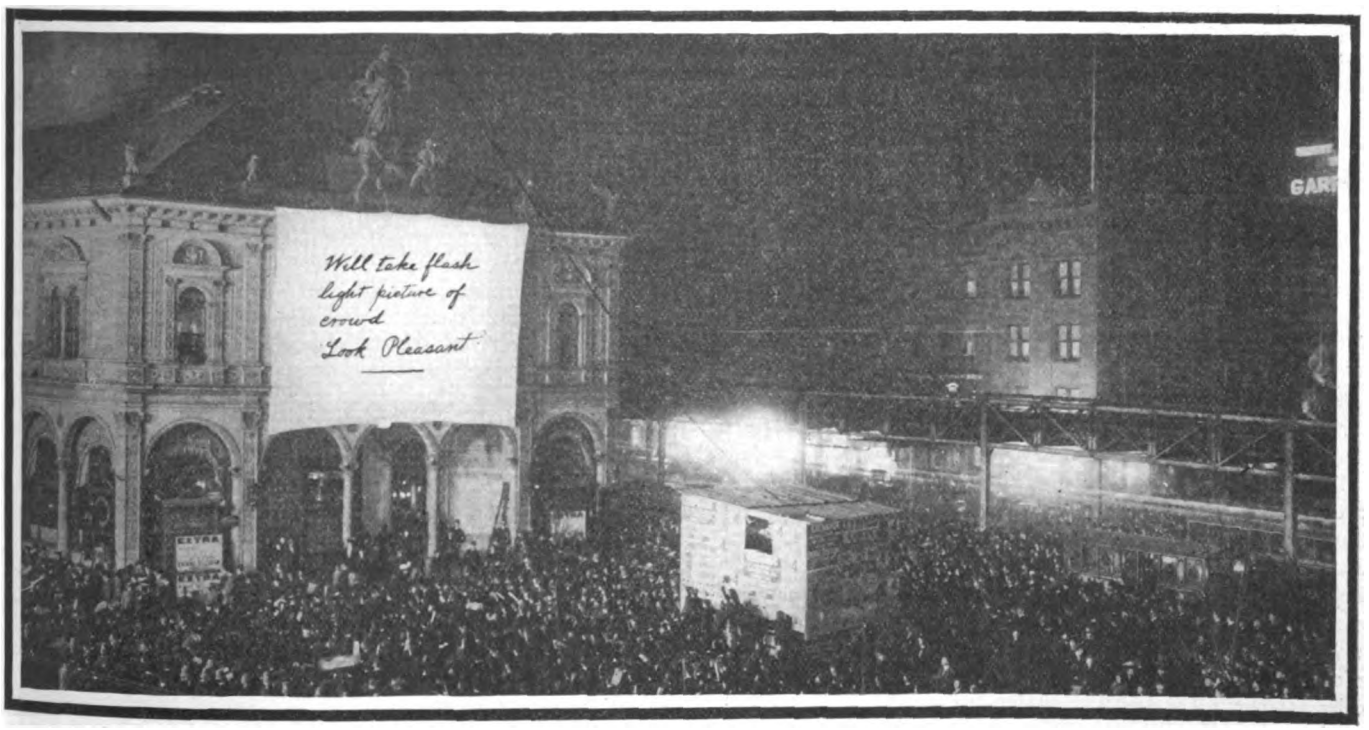
THE PART PLAYED BY THE TELEPHONE IN THE RECENT ELECTION.

By Edward A. Tyler.

THE recent Presidential election added one more triumph to the record of the telephone. In all probability never before was this instrument so much used for a single purpose as in this campaign. North, South, East and West the telephone lines lent their aid, and if their services were not always successful in securing desired results, they were at least impartial and treated all alike. As a mechanical aid the telephone surpassed all its competitors, demonstrating its reliability in a way which proved beyond all question of doubt its superiority to other methods of communication.



Crowd in Front of New York Herald Reading Returns as Received by Telephone. (From a Flash Light Photograph.)

In many instances local campaigns were conducted by telephone and quite frequently long-distance messages were sent which materially aided the results of the election. President Roosevelt held daily conferences by telephone from Washington with the headquarters of the National Republican Committee in New York City. The Democratic nominee was in daily communication with his advisors, and in some of the Western States, notably Wisconsin, the candidates for various offices were almost continuously in touch with their constituents.

The crowning success of the telephone came when the returns were being distributed throughout the country. With but few exceptions, every company made special arrangements, so that their subscribers or the general public could know the results as soon as they were declared. In the larger cities, where there were both Bell and Independent companies, keen rivalry existed in distributing the news, each vieing with the other in giving the correct returns at the earliest possible moment.

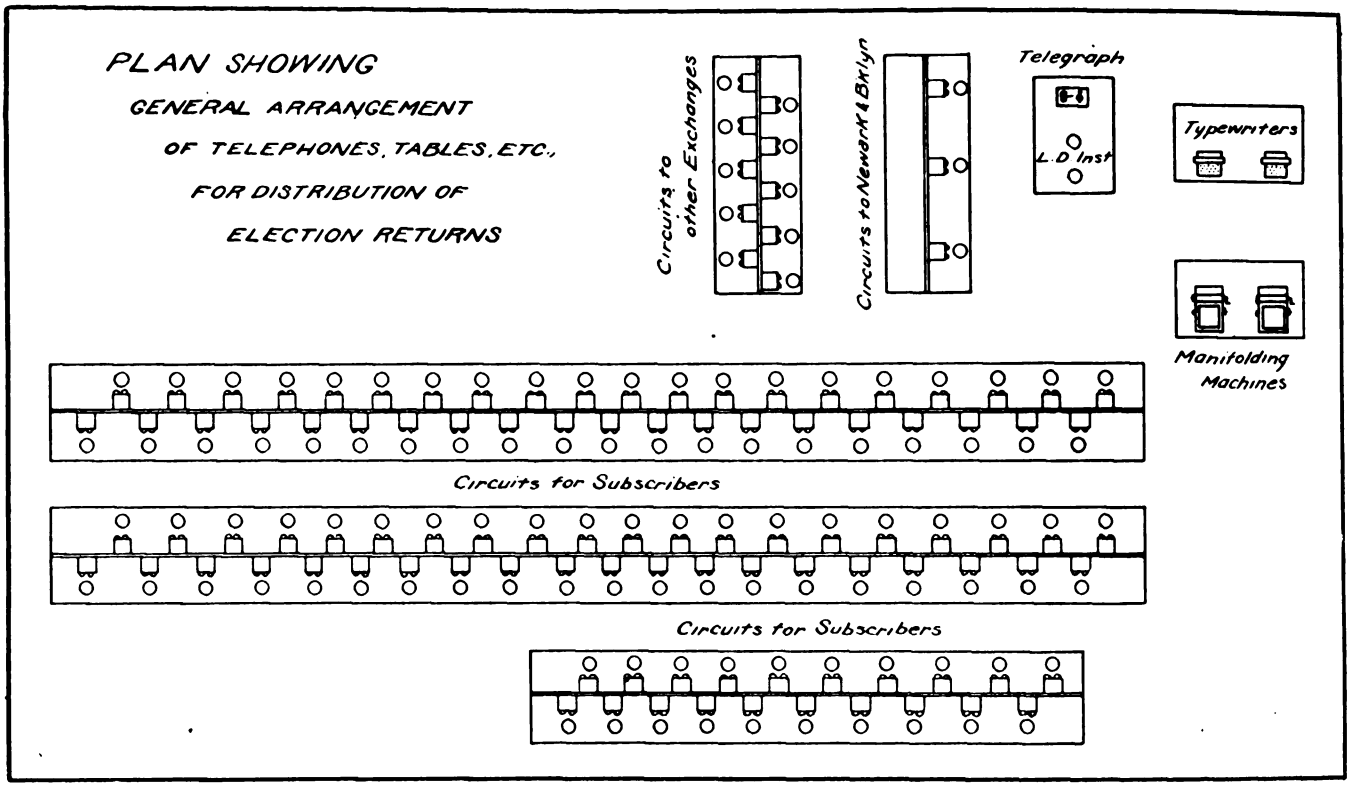
In New York City, the New York telephone company had made elaborate preparations which involved the use of one entire floor of the John street exchange building and necessitated the services of 215 employees, besides 38 others distributed among the nineteen branch offices in the city and 58 at the twenty suburban exchanges.

The utmost care was exercised in arranging details, special instruction sheets being printed which outlined the work to be done and specifically assigned the men to their duties.

The general plan of the arrangements at the John street exchange can be gained from the accompanying diagram.

Through the center of the room three temporary tables were built, each having a dividing partition about eight inches high running its entire length. On this partition were mounted the bells and drops of the instruments. Two of the tables accommodated forty telephones, twenty on each side; the other, twenty, ten on each side. These one hundred telephons were divided into five sections, *A, B, C, D, E,* each in charge of a foreman and a relief foreman. To each section twenty-seven men were assigned,

Digitized by Google



Arrangements Made to Receive and Distribute Election Returns by the New York Telephone Company at the John Street Exchange.

whose duties were to transmit the reports and to immediately clear any trouble that might occur. Besides the hundred lines there were special circuits to all of the branch exchanges, which terminated at another table. Twenty-five men were assigned to this in charge of a foreman.

The returns were received over two long-distance circuits and a reserve telegraph circuit. As soon as a report came in it was handed to a messenger, who gave it to one of a corps ot twelve men, whose duty it was to summarize, tabulate, edit and prepare the bulletins for the typewriters, of which there were two. As soon as they were printed they were turned over to the manifolders, which turned out twenty-four copies at a time. There were four machines employed on this work and a total of 15,000 bulletins were turned out.

These bulletins, as soon as they were printed, were distributed to the operators, who in turn repeated them to the subscribers. Four men were assigned to special duty at Police Headquarters to report any event of importance. The regular operating forces of all the exchanges were on duty, together with a large number of reliefs, in all about 1,000. As a rough estimate 10,000 calls were received for election news at John street and about four times that number at the other exchanges.

The special circuits were all wired into idle jacks in the main exchange, something like five hundred feet of cable being used. Trunk lines were connected to exchanges in Brooklyn and Newark, over which the news was distributed to points in Long Island and New Jersey. The special men detailed for the work reported at various times from 4 P. M. till 7 P. M. and remained on duty till about 2 A. M.

Aside from those to whom the telephone gave the news direct, all the daily newspapers employed special circuits in addition to their regular equipment and telegraphic service.

Election night in New York is a banner night in its history. Hundreds of thousands of people promenaded Broadway in the vicinity of the uptown offices of the papers, congregating in front of the bulletins in dense crowds. To enliven the intervals between reports moving pictures and stereopticon views were thrown on large canvas sheets. The crowd in front of the *Herald* building was probably the densest of any. This was mainly on account of its position at the intersection of Broadway and Sixth avenue.

In anticipation of the crowd that was expected, preparations were made to take a flash-light picture. A reproduction of the view is given herewith. In many respects this was a most remarkable photographic feat, as the results clearly indicate. Usually in taking a flash light the powder is fired off in one spot with but ordinary success. To be certain of getting the best possible results a wire was strung across Broadway from the *Herald* building to Macy's store. On this was hung four separate flash-light lamps about ten feet apart. Just before the powder was fired off the notice shown in the picture was thrown on the screen. At seven minutes past eight the powder was ignited, everything went off satisfactorily, and forty-five minutes later the picture was reproduced upon the screen. Two and a half pounds of powder were used to secure the result, and the success of the scheme is shown in the clearness of the photo, which could almost be taken for a daylight exposure.

In front of the City Hall another crowd which reached from Park Row to Broadway, a distance of about 100 yards, watched the bulletins of the N. Y. *Journal* and the *World*. Both these papers had special attractions in the way of lightning artists and moving pictures to entertain the people. The *World* arranged a series of signals in the shape of colored lamps, which surmounted the dome 300 feet above the ground, to indicate which candidates were successful. In various parts of the city fireworks were being continuously discharged. The part played by the telephone was not as spectacular, but its use alone made possible the other jollifications. Without the news there would have been no necessity for the special preparations, and even if they had been delayed till another time the delay would have robbed the display of most of its usefulness. Hence the telephone was the really successful candidate, being the people's choice for distributing the returns.

HAMILTON HOME COMPANY OPENS NEW OFFICE.

THE Hamilton, Ohio, Home Telephone Company has completed the installation of its new exchange at Reilley. This company has had a most prosperous year and has increased its number of subscribers considerably. Quite recently it purchased the West Butler County exchange at Scipio. This, with other extensions and improvements, has greatly benefited the company's service to the western part of the county.

THE PRIVATE BRANCH EXCHANGE AS A BUSINESS BUILDER

ARTICLE IV. CIRCUITS AND THEIR OPERATION.

By A. Dallam O'Brien.

PRIVATE branch exchanges may be designed to operate in connection with either a magneto or a common battery central office, in the former case the extension stations to the branch exchange being each equipped with separate transmitter batteries and operating as magneto instruments. The arrangement of the circuits and their design and operation in the case of a magneto system, is a comparatively simple matter, and will not be considered in detail in this article, as the use of the common battery exchange for this purpose is becoming more and more general, and furnishes a subject of greater interest. The first requisite for the line circuit which connects the branch exchange and its extension station is that battery should be furnished to the line in order that the branch may be signalled from the extension by the removal of the receiver from the hook.

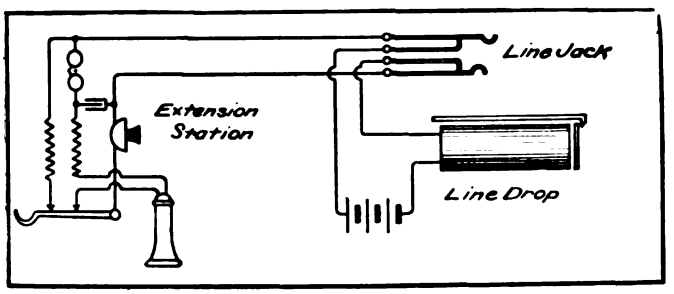

Fig. 1.

Probably the simplest method of accomplishing this result is shown in Fig. 1, and this circuit, with greater or less modifications, is the possible basis for the line circuit in use in all of the common battery private branch exchanges operating at the present time. By referring to the figure it will be seen that the jack at the switchboard, in which the extension line is terminated, is equipped with four contact points, the two inner contacts being arranged to be cut off from the circuit when a plug is inserted in the line jack. The line from the extension terminates at the long springs of the jack, while connected to the inner contacts is a drop or magnetic signal and a source of battery, as shown in the diagram.

From this description it will be apparent that the removal of the receiver from the hook at the extension station closes the circuit from the battery through the station and the line drop, and by energizing this drop signals the operator. In some types of switchboards for this purpose the drop is replaced by a relay which operates when the line circuit is closed, and by its operation closes a local circuit in which is included a small incandescent lamp, and in this way the branch exchange may readily be equipped as a lamp signal board. In either case the operation of answering at the switchboard cuts the signal equipment out of circuit and restores it to its normal condition except where a drop is employed, and in this case the shutter must be restored by hand. As the drop, or relay, is not connected across the line circuit when the line is busy, there is no path for the talking current through the signal circuit, and for this reason a low resistance drop or relay may be employed, the only necessary feature being that it should have sufficient ampere turns to enable it to operate with the current which is sent through it.

The trunk lines which connect the branch to the main exchange are of necessity somewhat differently wired at the branch end, as owing to the fact that battery is applied to the trunk line constantly at the central office end, it is necessary that precautions should be taken to prevent the continual flow through the trunk line signal at the branch exchange; for this reason a condenser is inserted in series with the trunk line drop, and this offers an effectual bar to the passage of the battery current from the central office. The presence of this condenser in the trunk circuit makes it necessary for the central office operator to ring over the trunk line when signalling the branch exchange, as the alternating ringing current will readily pass through the condenser and operate the drop. As in the case of the line drop, the trunk drop may be replaced by a relay which operates to close a local circuit, including a small incandescent lamp, and thus provides the board with lamp signal equipment throughout. The arrangement of the trunk circuit is shown in the diagram of Fig. 2.

The connecting cord circuit furnishes the most complicated arrangement incident to the exchange, as it is necessary to provide in the circuit for supervisory signals, by means of which the branch operator is kept constantly in touch with the condition of the connection. In Fig. 3 is illustrated a cord circuit arrangement employing a repeating coil and two supervisory signals, one in the answering and one in the calling cord. This arrangement will be readily recognized as being closely related to the cord circuit of the common battery central office switchboard. By referring to the diagram it will be seen that the battery is bridged between the four windings of the repeating coil, each of which has a resistance of approximately 40 ohms, the size of wire, and the number of turns in the windings varying with the systems of different manufacturers. In series with the positive side of each cord is inserted a magnetic signal arranged to display its target when the magnet is energized and to drop the target when the flow of current ceases. The calling cord is wired through the contacts of a ringing key, and the listening key is connected, as shown in the diagram. In some switchboards both the answering and calling plugs are equipped with ringing keys, so that the stations may be called by means of either cord, but when the back cord is used solely for answering, and the front cord for calling, two ringing keys are unnecessary.

Upon receipt of a call at the branch exchange the operator answers by placing the answering plug in the jack of the calling line. The telephone at the calling station being removed from the hook, current flows from the battery through the supervisory signal and extension line, through the instrument and back to the battery, thus operating the supervisory magnet and causing it to display its target. By throwing the listening key on the pair of cords in use, the operator is placed in connection with the substation and can obtain from the subscriber the necessary information regarding the connection desired. Should the station to be called, be one which is connected to the private branch exchange, the operator places the calling plug of the pair in use in the jack of the desired line, and rings. As in the previous case, the appearance of the supervisory target notifies the operator when the called party has answered. When the receivers are replaced upon the hooks the supervisory targets drop and the operator is notified of the completion of the connection. Should either substation desire to attract the attention of the operator during conversation, it is only necessary to operate the hook at the extension, this action causing a movement of the supervisory target, as will be readily seen from the diagram, and thus attracting the operator's attention.

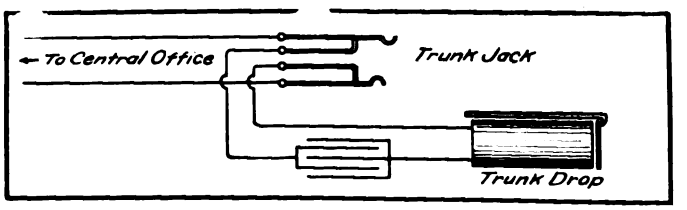

Fig. 2.

Digitized by Google

Should the call from the extension station be for a line reached over a trunk from the central office, the branch operator signals the main exchange by placing a calling plug of a pair in the jack of a trunk line, it being unnecessary in this case for the operator to signal by the use of her ringing key, as the circuit from the central office is closed through the plug at the branch exchange, and the line relay at the main office operated. In signaling the central office it is advisable for the operator to use a plug belonging to a pair other than that to which the extension station is connected, although at times it may prove advisable to use the other plug of the same pair of cords and allow the person at the extension station to ask the central office operator for the number desired. On trunk line connections the supervisory signal in the cord which is connected to the trunk line will not fall when the operator at the central office disconnects from the line, and in such cases it is necessary for the branch exchange operator to supervise the connection entirely by means of the signal in the cord which is connected to the extension line.

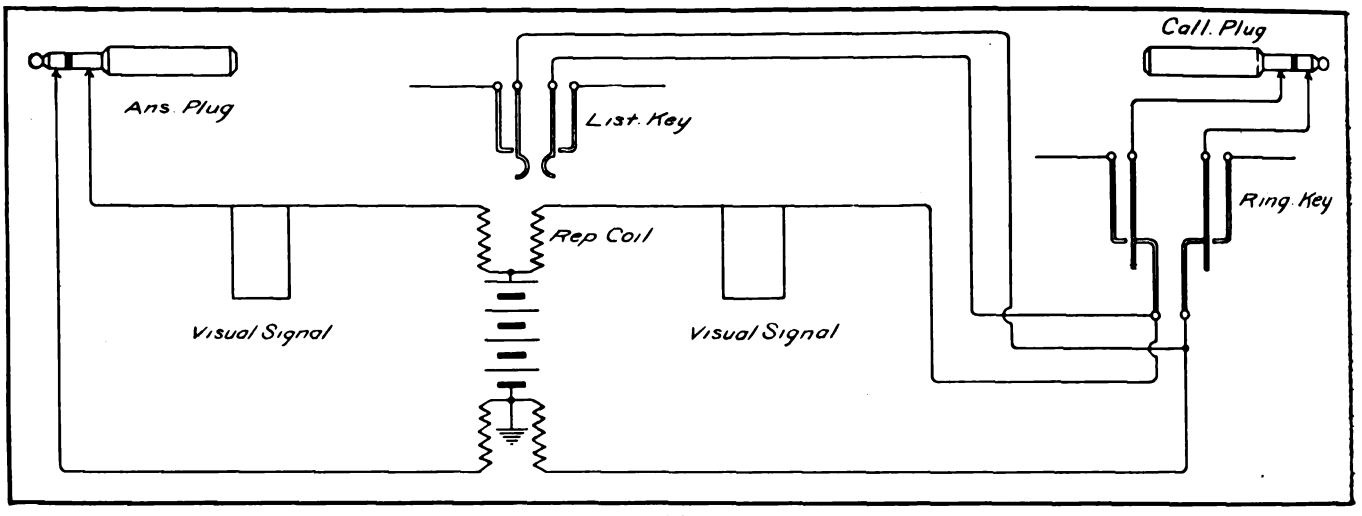

Fig. 3.

As in the case of the line circuit, the magnetic supervisory signal may be replaced by a relay which operates to close a local circuit in which is wired an incandescent lamp, and the supervisory signals thus be made lamp signals.

HINTS ON RURAL CONSTRUCTION

ARTICLE I.—LAYING OUT ROUTE.

By P. A. Price.

ONE of the first considerations in the building of a telephone system is the routing of the pole lines. Vital as the Central Office equipment may be, the reaching of subscribers, actual and prospective, is equally important, and an intelligent review of the territory to be covered will result in much economy of labor and material. In every community there are sections of territory that will sooner or later yield results to soliciting, and as careful provision should be made for their wants as in the established business and residence districts. Throughout the surrounding country there are farms and country places which need telephonic communication with the town. No haphazard, helter-skelter arrangement of lines will do; the routes and territory must be gone over systematically; so, first of all, map out the territory which it is proposed to include in the system, bearing in mind that just as much as the village or town is the commercial center of a certain area, so must the telephone system occupy a similar position. In every community a map of the surrounding territory can be procured, and from this ascertain the area of territory to be covered; then by means of soliciting, going over the ground in a thorough canvas, a general idea of the amount of prospective business can be discovered. Advertise. Get people talking telephone, and when you have the names and addresses of enough to justify going ahead with the work, mark their locations on the map. It will soon be seen that in some parts of the community there are a great many subscribers, while in others they are scarce and scattered. For this reason it is absolutely essential that the territory is thoroughly investigated. Now you are prepared to lay out the routes.

The location of the Central Office should be a happy medium between the business and the residence districts, but in a village where the local area to be covered is small the business section is usually selected for the seat of operations. It also frequently happens that the main street of the village is the principal outlet to the surrounding countryside, so if that be the case, it is well to arrange to take care of the country lines on the route as well as the short local lines. If the business section centers on the main street and is comprised within several blocks on either side of the thoroughfare, cable distribution would obviously be the best to chose. While its initial cost would be more than open wire, if there is any number of subscribers at all in the area, say twenty-five to fifty, cable would in the end be cheaper.

As to the route through the business section, the franchise gives the right to erect poles, maintain wires, etc., but these rights are not to conflict with those of property owners and others who might be inconvenienced, damaged, or injured by the poles, wires, etc. If it is decided to use cable construction, the poles should be set closer together than is necessary for open wire. For a well built cable lead, they should not be over one hundred and ten feet apart; for open wire they should average about forty to the mile, about one hundred and thirty-two feet apart. This, of course, depends a great deal on the weight or amount of wire they are intended to carry, but it is a safe figure for an ordinary line.

The distance determined on should be measured off with a line, and the location of the poles marked by a stake, or other positive method. If there are any electric light circuits on the same street, get on the other side of the road if possible. Keep away from light leads wherever you can. Having marked off the line through the business center, see if there is any objection to the locating of the poles as you have marked them off, and use all peaceful means to preserve the locations. A properly spaced pole line is a great factor in its life, as the strain of the wires and cables falls evenly upon it and does away with much guying.

Digitized by Google

The route through the business section being laid out, look up the map and see if the residence district can be made tributary to it, or if it can be extended to take in this part of the village. Perhaps it can, but the streets are lined with trees. Now, there is only one way to go up a street lined with trees, and that is by cable, with frequent distributing boxes. It is, of course, feasible to go up the back way, through a convenient alley, or on a private right of way, 'cross lots, back yards, etc., but if there are residences on both sides of the street, this would necessitate two separate routes, in the back yards or alleys of both sides.

Attempting to run an open wire lead through a row of trees lining a street is folly. To go over their tops with high poles is but putting trouble off for the future, for trees grow, and poles

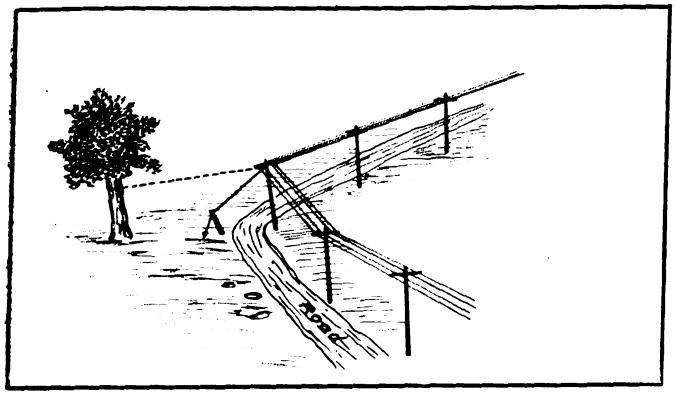

Fig. 1.

don't, and the expense of a high pole line, high enough to be clear for years to come, is well-nigh prohibitive for a small company to undertake. So if there are trees in any abundance along the right of way, use cable, and don't hang it too high in the air, either. You will find that the property owners will allow you to suspend the cable on the trees in preference to allowing them to be trimmed. The object in hanging it low in the trees is to keep it from swaying limbs and branches, which will injure the sheathing.

We have been discussing the case wherein the residence section is built up along the same street as the business locality. But it may set away from the main street. In this case, another route must be taken from the Central Office, and it may be practical to use open wire for a part of the way. But all the circuits enter the Central Office through cable, and if cable will have to be used in any quantity at all along the line, it would be best to make it all cable. Don't come out of an exchange with cable, run open wire for a way, and then go into cable again. It is poor policy. If it is possible to distribute to the subscribers with open wire all the way from the office pole, or carry the office cable to a distributing point and then go on with open wire, the use of cable is an unnecessary expense, unless the open wire lead will be of any great size, but for a lead on which cable will be used at all for the distribution of the wires, it is best to make cable all the way.

Open wires attract lightning, while cables, if properly grounded, will not be bothered except from that caught by the subscribers' loops, and if they are equipped with proper arresters the cable will suffer no injury. Try and make it a point to have the subscribers' lines leave the cable for good, when they do leave it, and not to go into cable again on the route.

From the two routes laid out, one through the business section, and another through the residence locality, it ought to be possible to reach all parts of the village, if of ordinary size. If there are a group of places, say warehouses and mills, apart from both residence and main business section, a convenient method would be to build the line from some point on either route as near to Central Office as possible. The reason for this is to divide the routes as much as possible without actually building separate ones, and will be explained later. Make all routes as direct to their distributing points as possible. Let the route through the business section carry the lead for the residence district if that is the more direct. Cable costs money, so does open wire, and poles will carry both. But that doesn't mean to carry either cable or wire in a roundabout way. The more compact the pole system the better, but get to the distributing point with the wire or cable in the most direct way.

Having thoroughly canvassed the village proper, if it is intended to include the country territory in the system, the extent of possible business should be ascertained at once. Many of the country lines will enter the village through either the business or residence section, and it is well to know what provision should be made for them on the open wire and cable leads.

Around every village of any size are hamlets, or small communities, which wish to be in touch with the larger town and with each other. Some of them may have telephone service from some other system with which it is proposed to make connection. Again, a small community may yield poor results in the way of residence service and still be profitable to a pay station. Sometimes a group of eight or ten or more subscribers for party line service can all be put on one circuit, so that they will be able to call each other and the Central Office as well.

In building farmer lines, some companies adopt the following plan with good results: The telephone company builds its lines along the main roads of the district likely to yield, or guaranteed to yield, the greatest number of subscribers. Then all subscribers living back from the main line are required to furnish poles, right of way, and labor necessary to reach the company's lead. The wire, brackets, arms and insulators are furnished by the company, with the skilled labor necessary to string the wire, install the instrument, etc. Sometimes a group of farmers are living near each other in a little "neck-of-the-woods" about a mile from the main line and want telephone service. The company would hardly be justified in building this line on the low rental received for service, and in this case the plan outlined above would be entirely satisfactory. The farmers could build the pole line at their leisure—the route being staked out by the company's superintendent—and the linemen would string the wire. In a mile of line the bill for labor—digging holes, setting poles, etc., would be considerable. In the majority of cases the farmers will agree to do this if it be firmly stated that it is imperative if they want telephone service.

Having determined which country roads will yield best results, and how many subscribers must be provided for, map out the district the same as the village has been gone over. Now everything is ready to estimate the amount of material required. Unless the distance to be covered is known, the following plan will be found serviceable: Take the diameter of a front wheel of

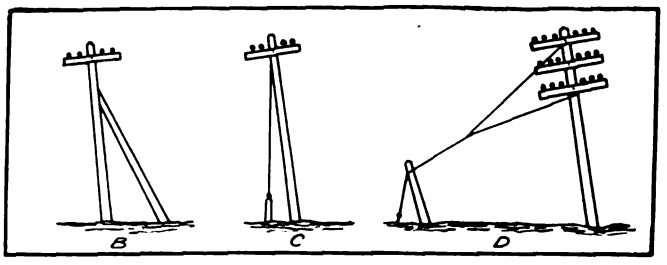

Fig. 2.

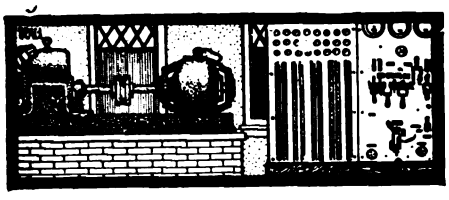
a buggy and multiply it by three and one-seventh; this will give the circumference or the number of feet gone over by one complete turn of the wheel. Forty poles to the mile has been suggested as a good spacing for pole lines. This means the poles are to be one hundred and thirty-two feet apart. See how many revolutions the carriage wheel must make to cover this distance, by dividing 132 by the circumference of the wheel. For convenience you can drop the fraction, as the pole line will be straighter than the route taken by the carriage. Say it comes out that the wheel makes fourteen revolutions in going the distance. Tie a rag or paper on a spoke of the wheel and count as you go along; every fourteenth revolution measures a pole space and should be noted down.

This will give a fairly accurate idea of the number of poles

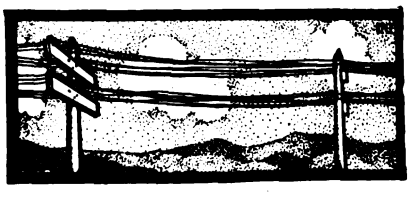
Digitized by Google

required, but other notes should be made as well. For instance, wherever the pole line turns a corner it should be guyed, that is, braced to stand the strain of the wires pulling around the corner. This guy should pull the pole in the opposite direction from which the wires are pulling, and on a sharp turn sometimes two guys can be used advantageously. A glance at the diagram will make the idea clear. Fig. 1 illustrates a case where there is no chance of guying directly to the ground, as the pole is too close to the road, so the guy wire must be taken to the other side. It may be that there is a convenient tree to which it can be attached, as shown by the dotted line. If there is no tree, either a "push guy" (*B*), Fig. 2, or a shorter pole must be placed across the road and the guy made fast to the top of it, in order to keep it clear of teams and high wagons. The "push guy," *B*, is a pole so set as to lean towards and against the pole carrying wires, and firmly fastened to it near its top, and serves to push the pole away from the direction of the strain of the wires. They are unsightly, and mar the appearance of a line, but are very satisfactory in serving their end. *C* shows how a pole may be guyed from a point near its butt, by means of an anchor, and *D* shows a "Y" guy for heavy leads. These will be explained in a later article.



QUERIES

Questions on any subject relating to telephony will be answered on this page.



PUSH AND PULL BRACE.—(453.)

We have heard of push and pull braces for pole lines. What are they and where used? G. N.

A push and pull brace is illustrated in Fig. 453a. It is used to brace a pole which may be set in soft ground, and as its name indicates it is intended to prevent the pole moving in either direction. Its method of application is shown in the diagram, attention being drawn to the cross piece *C*, which consists of a log about four or five feet long bolted to the brace *D* at *B*. The pole itself is bolted to the brace at *A*. A good way to secure a solid hold for the brace is to cover the log with stones, which will act as an effective ballast.

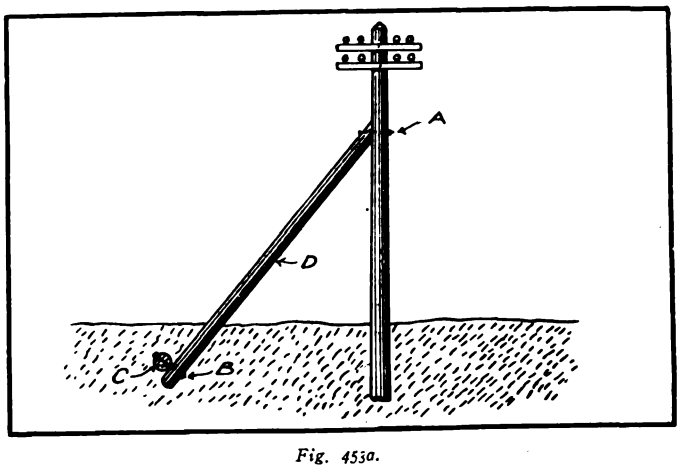


Fig. 453a.

Where the ground is very soft or marshy a method of bracing, which is illustrated in Fig. 453b is often used. In this case to the bases of the braces cross boards are securely fastened, as shown at *B*. A good width for these boards is 18 inches and about 2½ feet long.

When placed in position a similar method of ballasting should be used.

This method of protection for a pole line, although not as pretty as when guy wires are used, serves its purpose very well and at the same time insures the stability of a pole under almost any conditions.

RURAL LINES.—(454.)

We are building some country lines and expect to have a number of subscribers on each one. Would it be better to use metallic circuit and place all the telephones on one route on one line or to use grounded circuits and split them up. In the latter way we would not require so many different signals. Has it any other advantage? K. L. T.

It is our opinion that metallic circuits are the only ones which should be employed. Grounded lines are often noisy, and it is impossible to rid them of cross talk, especially if they are long. Selective signaling can be as well accomplished over a metallic line as on a grounded one by dividing the bells and connecting one set between one side of the line and ground, and the other set between the other line and ground and using a ringing key which will bridge the generator between either side of the line and ground.

If the lines are to be heavily loaded, it would be a good plan to build additional lines to take care of the subscribers nearer the exchange. The cost at the present time would be much less than later on, since you have the construction men right on the spot and it will take but little longer to put on pins and insulators and run the additional wires, which can be done at the same time the ones you intend to install are put up.

TRUNK LINES.—(455.)

We have two toll lines going to the same exchanges, *A* and *B*. We are going to open a new office at *C*, which is about 10 miles further out than *B*. Would it be better to run a trunk from *A* to *C* or could we use one going to *B* with cut in Jacks at that station. J. S. T.

The necessity for the new trunk from *A* to *C* is determined entirely by the amount of business done over the two trunks between *A* and *B*. If they are worked to their full capacity, then it is imperative to run a new trunk to *C* direct. If, however, one trunk from *A* to *B* could be spared for the joint services of *A*, *B* and *C*, then there is no necessity to run a new line, except that if business is expected to grow between *A* and *C* or *B* and *C* to the extent of utilizing the joint trunk exclusively for business between *A* and *C* and *B* and *C*, then the best policy would be to construct two trunks, one from *A* to *C* and one from *B* to *C*.

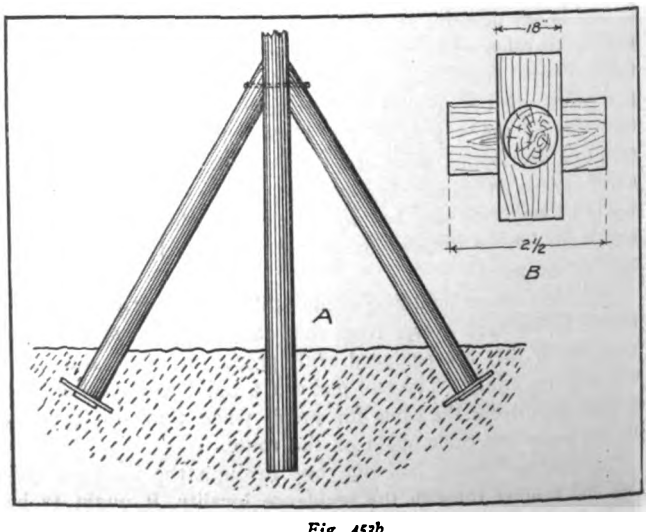

Fig. 453b.

For testing purposes the trunk from *A* to *C* should be cut in to the main frame at *B*, and be protected both ways with protective devices.

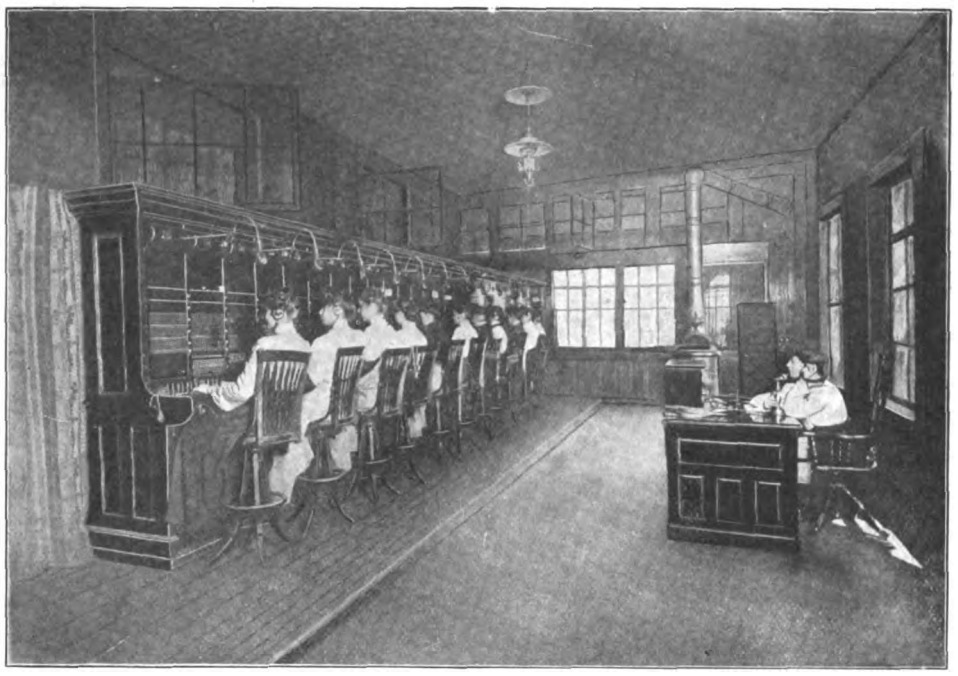
THE EXPERIENCE OF THE HOME TELEPHONE COMPANY IN SPRINGFIELD, MO.

TELEPHONE development in Missouri has been rapid and at the same time the companies which have dared to oppose the "Majesty" (?) of the Missouri and Kansas Telephone (Bell) Company have not had any cause to regret their advent into the field. Probably one of the best illustrations of the possibilities of up-to-date fearless management is offered in the success which has attended the Home Telephone Company of Springfield.

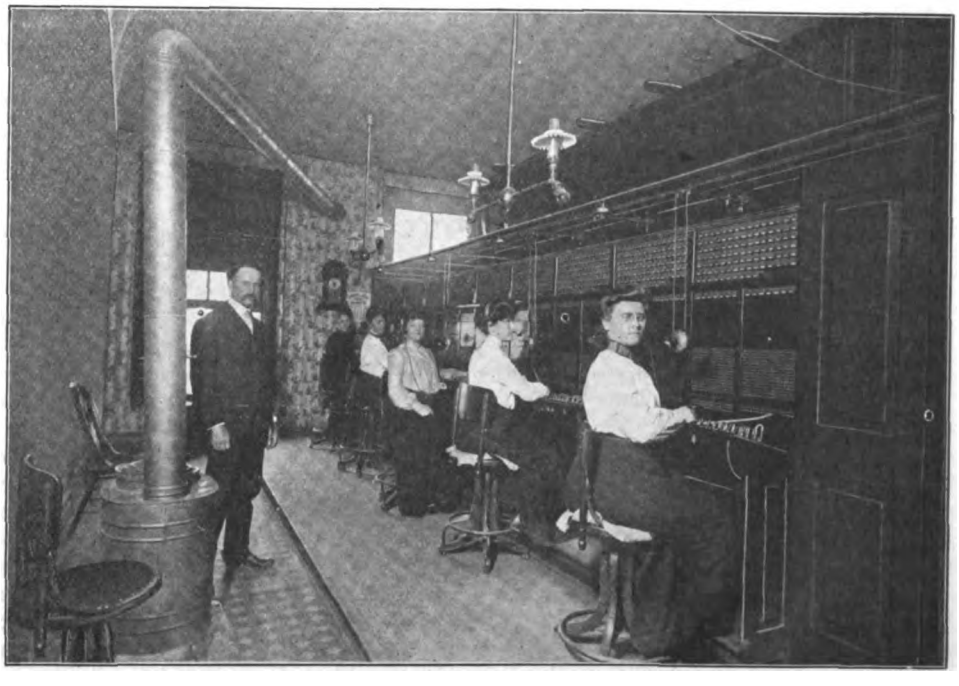


Office of the Home Co., of Springfield, Mo. Twenty Months in Operation.

Previous to this company's incorporation three others had attempted to start an exchange and went so far as to secure hundreds of subscribers, but unfortunately the intimidating action of the Bell with free rates and free telephones worked the desired effect, and the companies withdrew. The gentlemen who organized the Home company were made of sterner material, and notwithstanding the same tactics being applied to them as fell to the lot of their predecessors, they went ahead with the work of securing subscribers, and have to-day 1,900, although not more than 1,000 were expected. At the present time new telephones are being installed at the rate of 40 to 60 a month, and the switchboard capacity has recently been increased to take care of 2,500 subscribers..

The line plant is almost entirely cable, both aerial and underground systems being installed. For distribution purposes 146 outlets, or terminals, alone being used for connections to the aerial cables. The rates are $30 for business telephones, $20 for private line residence, and $12 for four party line residence; for the latter service the American Electric Selective system is used. Since the first of the year nearly 500 new subscribers have been secured, and when the long-distance lines which are being planned to reach Kansas City and St. Louis are completed it is more than probable that the number of subscribers will be greatly increased, if not doubled.

Perhaps the situation can be better understood by reference to the pictures, which need no explanation. These were secured to illustrate an advertising folder entitled "By the Will of the People," which created a great furore in the camp of the enemy, and dire results were prophesied. Not the least of these was that after its system was rebuilt, which was done this summer, they, the Bell, would replace every telephone of the Home Company with one of theirs. The most reckless inducements were made. Business houses were given one free house telephone with a rate of 50 cents per month for additional instruments, and in some cases contracts were dated six months ahead for private line service. Still the Home Company flourishes, which is a very good demonstration that the Will of the People is on the side of the Independent company.



Office of the Bell Co. in Springfield, Mo. Twenty Years in Operation.

THE ADVERTISER AND THE OPERATOR.

SINCE the inauguration of our new department, "In the Manufacturing Field," we have received hundreds of letters commending us for this matter. And, without exception, our subscribers are agreed that here they will find reading that will be as interesting to them as any other part of the paper. Some even go so far as to say that it will be "the most interesting part" of the paper. We are fully agreed with these correspondents, and it is our hope that we may be able to impress on all of our readers the fact that a careful perusal of this new department will repay them a hundred fold for the time expended. In a single line they may find material that will effect for them a saving of hundreds of dollars.

There is only one department that should be studied with greater attention, and that is the advertising section itself. We doubt if all our readers appreciate fully the advantages that are offered to them each week by our advertising matter. Unless a man is an instinctive reader of advertisements, as all men should be, it requires some little education to bring home to him the important bearing that a close study of the advertising section of a technical publication has on his prosperity.

When a concern has sufficient faith in its wares to pay good money for their exploitation in a trade publication, it may very well be believed that they can offer something worth while the attention of every live man in the trade. In a publication of general circulation, such as newspapers and magazines, a concern may be willing to risk its money in advertising an inferior article, for here it has to do with a class of people among whom there can be few experts who know the true value of the wares offered. But with a technical or trade paper all the readers are experts, and the advertiser knows better than any one else that he must be prepared to have his offer analyzed and judged by men who are as well posted as to values as the advertiser is himself.

Under such conditions no one will be fool enough to offer goods that are not fully up to the claims set forth. Therefore the continued advertising of any article or any firm in a trade paper is in itself absolute proof of the integrity and standing of the advertiser, and the reader who does not carefully examine the advertising announcements in his favorite trade publication lacks business intelligence.

The question was summed up admirably by Charles F. Speed, of the Washtenaw Home Telephone Company, Ann Arbor, Mich., who in a paper read before the Michigan Association convention, made this statement:

> "I save my salary and more every month, by answering advertisements and learning where to buy. Advertise what you have to offer and read the advertisements of what others have."

This statement ought to be borne home to every telephone operator in the land. It ought to be framed and hung up over the desk of every telephone manager, for what is true in Mr. Speed's case is true in the case of every other man engaged in the telephone business. Such a man, if he will only read the advertisements in his papers carefully, can certainly save his salary and more every month, and in addition acquire a store of mighty valuable knowledge.

It is because we are so fully impressed with the importance of our advertising section that we have recently made a departure in the arrangement of THE AMERICAN TELEPHONE JOURNAL, interleaving in the back part of the paper text pages with advertising pages. As a general thing, we are happy to say the new arrangement has met with endorsement as distinctive as the inauguration of the manufacturing news department. But we have also received a number of letters finding fault with us for inaugurating this new departure. One man writes:

> "I do not like the reading matter broken into by advertisements. I wish you would return to your old system."

Another, an engineer in a big manufacturing concern and a man who ought to have a broader view, has this to say:

> "I want to have my Journals bound when the volume is complete, but I don't care to have a mess of advertisements mixed in with the reading matter. Change back to the old style by all means at once.

It is to those of our readers who view the matter in this light and who are, we hope, very few, that this editorial is especially addressed. We ask that they will take it to heart. The "mess of advertisements" to which our correspondent noted above refers to so contemptuously, constitutes the backbone of the telephone literature of to-day. Without the "mess of advertisements" it would be absolutely impossible to publish THE AMERICAN TELEPHONE JOURNAL. It is the advertisers who are supporting this paper, and not the subscribers. The sale of THE AMERICAN TELEPHONE JOURNAL at $1 a year involves a loss to the publishers. This loss is met and overcome by the revenue derived from our advertising columns. Naturally, therefore, it is to the interest of our subscribers, as much as it is to our own, to see that value is returned to our advertisers for their investment with us.

We have had thousands of letters praising this paper for the course it has pursued, for the fine character of its contents, for its value as an instructor, as an upbuilder of the industry and a defender of the Independent industry against Bell aggression. And almost without exception these subscribers have marvelled at our ability to give so much for so little.

The answer to this marvel, as we have stated, is to be found in our advertising columns. Our subscribers can discharge their obligations in this matter by following the matter in these advertising columns, and placing their trade whenever possible with the houses that are there represented. By doing this they will insure the continued prosperity and continued betterment of their publication. By not doing it they lose an opportunity to strengthen the industry and strengthen the reading matter that comes to their desk every week.

It may be objected that the recognition of the manufacturer's claims as the chief support of a trade paper, if allowed, would militate against an independent and dignified course on the paper's part; in other words, that the manufacturer, being the chief source of financial revenue, would dominate the editorial policy to the detriment of the interests of the subscriber. The answer to any such objection is very simple. It lies in this: No publication that does not cater primarily to the interests of the people who are on its subscription list has any value as an advertising medium. Therefore, aside from questions of sentiment or policy, no editor who understands his business can afford to allow even the most liberal advertiser to influence the matter that appears in the text section. We believe it does not require any special testimony to make clear the fact that the editor of THE AMERICAN TELEPHONE JOURNAL has always lived up to this conception of the duties of the paper towards its subscribers.

SOME FACTS RESPECTING THE JOURNAL.

The Telephone in the Courts

Conducted by A. H. McMillan.

Readers are invited to submit questions on any point of Telephone Law. They will be answered and explained on this page.

CONNECTIONS BETWEEN COMPANIES.

Some time ago, we secured a contract in competition with the Bell Company for the installation of a private exchange of about 225 telephones in a large hotel in this city, and as usual during the preliminary skirmishing, the Bell Company made a great deal of capital of the fact of their having extensive long distance connections and claimed that the exchange would be of little use to the hotel patrons without their long distance service. We got around that point by agreeing in our contract to furnish space in our board for a Bell long distance connection and agreeing to give the Bell Company all of the long distance tolls which might originate at any of the telephones in the hotel. We have the exchange installed and in working order and the Bell is now trying to crawl out of the long distance part of it on the grounds that they never, under any circumstances, connect with private exchanges using apparatus other than that furnished by the Bell Company. Can we not force the Bell Company to make this connection?

S. Tel. Co.

I DO not believe that the Bell Telephone Company can be compelled to connect with a rival company in the manner desired. The obligation that a telephone company is under as a common carrier is to furnish telephones to all people who wish to become subscribers in compliance with its reasonable regulations, but in the absence of a special legislation this has never been held to extend to connecting with the switchboard of a rival telephone company, and I doubt very much whether the courts would be willing to so extend it. At common law one carrier could not demand as a right that it be permitted to use its rival carrier's property for the benefit of its own business.

Two cases of somewhat this kind came up under "the transportation corporations law" of New York, which provides in section 103 that "Every such corporation shall receive dispatches from and for their telephone lines or corporations and on payment of the usual charges by individuals for transmitting dispatches." . . . It is held that this statute does not require one telephone company to supply connections with another telephone company so that the latter may use the connection established as part of its own and transmit thereover its own messages on payment of the merely nominal sum required by ordinary subscribers.

Bell vs. Hudson River Telephone Company, 19 Abb. N. C. 466, to the same effect is a more recent case. In re Baldwinsville Telephone Company, 53 N. Y. S. 574. People vs. Central New York Telephone Company, 58 N. Y. S. 221. In this latter case common law rule is laid down as I have stated it above.

The one case compelling connection between telephone companies was that of Campbellsville Company vs. Lebanon L. & L. Telephone Company, 88 S. W. 1114. This was a case that arose in Kentucky and was decided last May. The relator was the successful party. The case was decided under a section of the constitution of the State, which declared that telephone companies or exchanges in different towns or cities should receive and transmit each other's messages without unreasonable delay and discrimination. The two companies also had a contract for the exchange of service which rendered the case still different from the one we are considering. I think that in the absence of a constitutional or statutory provision that you have no relief.

HIGH AND LOW TENSION CURRENTS.

THE Des Moines Edison Light Company is in the courts asking a temporary injunction restraining the Mutual Telephone Company from erecting and maintaining a line of poles and wires along a certain alley in the city of Des Moines, Ia. The petition is based on city ordinances which say that where two lines of electric wires occupy the same street or thoroughfare, one line carrying a high and dangerous current, and the other a weak current, they shall be erected on opposite sides of the street. The Edison Company alleges that it has, and for some time has had, its lines established on the north side of the alley in question, some of its wires carrying currents of from 230 to 2,300 volts, while the arc light wires carry currents of 4,000 volts, a current highly dangerous to life.

It is claimed that on July 28 the Mutual Telephone Company erected a line of low current wires on the same side of the same alley; that its poles were about the same height as the poles of the light company and mingled the wires of the two companies. It is said that there have been several contacts established, which, in case of rain, would ground the wires of the light company with danger of burning out the same and killing anyone who might come in contact with the poles while they were carrying the high currents.

ALDERMEN CITED FOR CONTEMPT.

THE mayor and members of the common council of Red Lodge, Mont., have been cited to appear and show cause why they should not be punished for contempt of court for disobeying an order of the court by refusing the Rock Mountain Bell Company the right to construct its lines in the city of Red Lodge. The trouble between the city and the company began more than two years ago, when the company attempted to build their toll and exchange lines within the city. At that time the linemen and superintendent of the company were arrested for violating a city ordinance which had been recently passed for the purpose of stopping the company from building the lines. Heavy fines were imposed on the employees of the company by the police magistrate. The company took an appeal to the district court on the ground that the fines were excessive, and won its appeal. However, an injunction, secured to compel the company not to interfere with the construction of lines, was dissolved, it being held by the court that the city had the right to determine whether the telephone company might do business within the city. A reversal of this decision was secured in the supreme court. It is now claimed that the city is retarding the building of lines and denying the company rights given them in the supreme court decision.

RECORDING OF FRANCHISES.

THE Central Maine Telephone Company and the Somerset Farmers' Co-operative Telephone Company at Skowhegan, Me., are in difficulties over an attempt by both companies to enter the town. The Central company alleges that the Farmers' company has not recorded its permit, and so is debarred from entering. Under the statute governing the procedure on petitions of this nature, the permit, if obtained, must be recorded within one week after it is granted, to allow of appeal to the Board of County Commissioners. The selectmen of the town, in granting permits to the two companies, made the recording of these instruments a prerequisite to their validity and provided that the permits should not be deemed accepted until recorded by the companies. Both permits were granted on August 27. That of the Central Maine Company was recorded on that day, but that of the Farmers' Company has not yet been recorded. The Central Company claims that this failure to record the permit within the statutory period renders the proceedings void as a whole, and it will take measures to prevent its rival from entering the town if it tries to do so.

Digitized by Google

IN THE OPERATING FIELD.

NEW TRAFFIC RULE OF ROCHESTER HOME COMPANY.

THE Rochester (N. Y.) Home Telephone Company, anxious to give its patrons the best possible service, recently sent to each of its subscribers a circular asking that they indicate on a postal card enclosed their desire as to the continuance or discontinuance of the practice of calling back for connections with lines that were busy when first called.

Out of 2,036 replies received, 1,025 were for the system, 973 against, and 38 were indifferent. The company has therefore resolved to adopt the following system: "When a line that is called for is busy, the operator will say, 'The line is busy.' The calling subscriber desiring to be called back should then say, 'Call me.' If the operator does not get this request after reporting the line busy, it will be assumed that the subscriber does not care to be called back and no record of the call will be kept. Briefly stated, busy lines will be called back for connections only when so requested by the calling subscriber."

COMPARISON IN INDIANA.

A COMPARISON of the new directories of the Indianapolis Telephone Company and the Central Union Telephone Company shows that the number of new Independent long distance offices in Indiana is 1,322, while the number of Central Union offices in the state is 411. The number of offices reached by the New long distance and not by the Central Union is 1,036, while the number of offices reached by the Central Union and not by the New long distance is 125. The number of offices common to both is 286.

LONG-DISTANCE SYSTEM OF MARYLAND CO.

THE Maryland Telephone Company is pushing the work upon the extension of its long-distance lines. Delays have been caused by the difficulty in securing right of way, but this has been generally overcome, and it is expected that the Western lines which will give long-distance connections with Chicago, St. Louis and Western cities, will be completed by the first of December. Special preparations are being made for the opening of these lines in the form of a convention at which all the prominent financiers and business men associated with the company will be present. The ceremonies will close with a banquet.

PORTLAND, ORE., TO REPEAL BELL FRANCHISE.

AN ordinance to repeal the franchise of the Pacific States Telephone & Telegraph Company, at Portland, Oregon, was recently introduced in the Council and referred to the judiciary committee. In addition to rescinding the rights granted to the present company the ordinance provides that the franchise be advertised and granted to the company offering the greatest inducements.

The service furnished by the Pacific States Company has not met with the approval of the citizens, and it is believed the commercial and business interests of the city would be better taken care of by an Independent company.

RAPID LINE CONSTRUCTION.

A RECORD in line construction was recently made by J. A. Driscoll, the newly elected president and general manager of the Wayne County Telephone Company and the Wayne-Monroe Telephone Company, of New York. It occurred to Mr. Driscoll that it would be advantageous to the patrons of both systems if they could be connected together to hear the election returns. The directors thought it impossible, as it required the building of seventeen miles of line, but Mr. Driscoll was not discouraged and at once put several gangs of men at work to dig the holes along the route between Lyons and Sodus. The poles reached the different localities on Thursday and Saturday. By continuous work from then on till Monday the line was completed.

The building of this line incidentally placed both the systems in communication with almost every village in Wayne county, and also with Rochester, Syracuse and Independent companies in Ontario, Seneca, Cayuga, Jefferson, Oswego, St. Lawrence and the counties in the Black River district.

A NEW NEW YORK COMPANY.

THE Oxford Valley Telephone Company, which was recently incorporated, will construct a system that will ultimately connect with every point in Chenango County, and form another system in the chain of exchanges which extend into every part of Central and Northern New York. At the present time connections will be made with the Marquis system at Norwich, on the north, and with the Chenango Valley Company, of Chenango Bridge, on the south. In this way long-distance connection will be made with Binghamton, Utica, Buffalo and other points.

CITIZENS' COMPANY, OF SIOUX FALLS, EXTENDING ITS SYSTEM.

THE new directory recently issued by the Citizens' Telephone Company, of Sioux Falls, S. D., gives a list of upwards of fourteen hundred local patrons besides the names of parties on farmers' lines in fourteen different divisions throughout the country. Long-distance lines are being built as rapidly as possible, which will greatly add to excellent quality of service which the company is now furnishing.

At the present time connections are furnished with all towns between Sioux Falls and Dell Rapids, Colton, Canton, Worthington, Minn., and on to St. Paul, Minneapolis, and La Crosse. Within a few days connection will be established with Salem, the line being now complete beyond Montrose and within thirty days the new line to Yankton will be in operation. The latter circuit is being built by the Independent Telephone Company, of Yankton, with which the Citizens' Company has a traffic agreement. Besides the long-distance service the company is continually adding new subscribers to its local system.

NEW SYSTEM FOR NEW BERN, N. C.

THE Home Telephone and Telegraph Company, under the direction of F. C. Toepleman, general manager, has recently installed one of the most up-to-date telephone systems in the country. The switchboard is central energy of the most improved type, and the line plant is built throughout under a multiple cable method of distribution, no open wire lines except the leads to the subscriber's premises being used. Over 18,000 feet of cable has been strung, which will give an ultimate capacity of 800 lines. At present only one-half is being used, but it was thought best to allow for future development. A particularly pleasing feature in the outside construction is the neatness of the pole lines, which reflect great credit upon the builders.

The power for operating the exchange consists of a one-horse-

Digitized by Google

power motor, which drives an electric generator. This is used for charging a set of storage batteries that furnish the current for both signaling and talking.

When Mr. Toepleman first came here there were less than 100 subscribers and but one out-of-town line to Bayboro; now the Home Company operates seven long-distance circuits, which afford connection with the principal cities of the country. The plant was designed and the construction work carried out under the personal direction of Mr. Toepleman, in which he has been ably assisted by Mr. L. F. Wright, foreman in charge, and G. A. Barnes, W. S. Allen and Fred Smith.

TESTING OUT THE MEASURED SERVICE QUESTION.

MR. FRANK SAPP, who recently joined the forces of The Controller Company of America, as announced in THE AMERICAN TELEPHONE JOURNAL, has settled down to an interesting experiment in Sandusky, Ohio.

Frank Sapp.

Acting in behalf of his company, Mr. Sapp is going to test in an exhaustive manner the question of measured service versus flat rates. He will work in conjunction with Manager Carl C. Curtis, of the Sandusky Home Telephone Co., in an effort to demonstrate the superiority from a commercial and financial standpoint of the measured service system over the flat rate which is now exclusively in use in Sandusky. It is expected that the experiment will consume several months, and the results are certain to attract very general attention.

UNDERGROUND SYSTEM FOR PEOPLE'S COMPANY OF KNOXVILLE, TENN.

THE People's Telephone Company, of Knoxville, Tenn., is installing a complete underground system in the business part of the city. The cables used are of the most approved type, and vary in capacity from 50 to 200 pair. During the past season six carloads were purchased, all of which has been installed. As soon as possible the subscribers' lines will be transferred to the underground conductors and the aerial wires will be taken down.

INCREASES ITS SWITCHBOARD TO THREE TIMES ITS ORIGINAL CAPACITY.

THE Merchants' Mutual Telephone Company, of Michigan City, Indiana, will put in operation a new switchboard which will have a capacity of 2,400 lines.

This company has had an unusual amount of prosperity during the last year, which necessitated the new switchboard. This board is three times the size of the old one. The company will extend its line plant early next spring, having contracted for five miles of 200 pair cable.

UTICA HOME COMPANY MADE SPECIAL ARRANGEMENTS FOR ELECTION RETURNS.

THE Home Company, of Utica, New York, made special arrangements to give the election returns to its subscribers. In order that its patrons might receive the returns from other States and New York City, where it has no connection, arrangements were made with the Postal Telegraph Cable Company whereby it installed in the Home Company's building, beside the information operator's desk, instruments on its main lines, and a corps of operators. As soon as any telegraphic messages came over the wire, they were handed directly to the information operators, who then gave the information to the public asking for it. Special lines were run and extra information operators on duty assisted in order to give the public the quickest possible service.

THE MUTUAL COMPANY, OF DES MOINES, EXTENDS ITS SYSTEM.

THE Mutual Telephone Company, of Des Moines, Ia., has upwards of 2,700 telephones in service and is installing new instruments at the rate of about twenty a day. This company has made a number of improvements to its system and is now furnishing a telephone service of a higher grade than was ever done in Des Moines under the Bell regime. The long-distance service of the company is being extended and connections are made with a number of the rural lines in this part of the State.

C. H. Judson, probably one of the best known managers in the Independent field, has been secured to look after the business of the company. Mr. Judson formerly had charge of the system of the Home Telephone Company at Kansas City, Mo., where his knowledge of telephony and untiring energy brought the subscription list to a point beyond expectations.

MADISON, WISCONSIN, BENEFITED BY INDEPENDENT COMPANY.

THE following letters very plainly indicate that the people of Madison appreciate the service given by the Independent telephone company. Here, as elsewhere, the only losers are the Bell, who too late attempted to change their short-sighted policy.

"MADISON, Wis.

"Madison has been benefited in every way by the establishment of the Independent telephone plant, as far as my observation goes. The service is better than that given by the old company before the new one was established. One can have both telephones in his house or office for less than the old company used to charge for one. The rates are so reasonable that nearly everyone has a telephone, making the service of much greater value than before. In addition to the city list, we reach over the lines of the Independent company 1,000 subscribers in the villages and on farms in Dane County.

"E. RAY STEVENS,
"Judge Ninth Judicial Circuit."

"MADISON, Wis.

"I have been a subscriber of the Dane County Independent telephone system for a number of years and have found the service to be uniformly good. At the time of the installation of the Independent telephone system the Wisconsin Bell Telephone Company had a little over 200 subscribers, for which it was charging the rate of $50 a year and furnishing therefor an inferior service. Since the Independent telephone started the Bell Company has spent a large amount of money in rebuilding their plant, but seem unable to get a hold of the business. I am fully convinced that so far as telephoning is concerned that the business interests in the city of Madison have been greatly benefited by the construction of the Independent telephone system, and if I may judge from the rate charged in other cities by the Bell Company, where there is no competition, a large amount of money has been saved to the citizens of Madison. I think that the fact that there has been competition here has materially increased the number of subscribers for the Independent system, which in my judgment has resulted in a better quality of service. Further, there is in the neighborhood of 1,000 farmers throughout Dane County having connection with Madison over the Independent company's lines. From my experience in Madison I am fully convinced that if I moved to a city where the Wisconsin Bell Telephone Company had a monopoly I should favor granting an Independent franchise to any reputable firm applying therefor.

A. J. SCHMEFEMAN.
"Member of City Council."

At this time, when the agitation for Independent systems is being made in many of the strongholds of the Bell, these letters will be opportune.

CLINTON, N. Y., HOME COMPANY EXTENDS ITS SYSTEM.

THE Clinton Home Telephone Company, of Clinton, N. Y., has been making every effort to extend its system and at the same time satisfy the subscribers with gratifying results. Quite recently an exchange was opened at Westmoreland, and the people at Deansboro are asking for an exchange, promising fifty subscribers for a start. During the past year seventy-five new subscribers have been added to the list in this village and orders for others are being received almost daily.

IN THE MANUFACTURING FIELD

"SUCCESS LIES IN THE KNOWLEDGE OF OUR TOOLS"

THE ANDERS PUSH BUTTON TELEPHONE.

It looks like a push button. Examine it closely and you find it's a telephone, and yet it is still a push button. This may sound paradoxical, but it is true nevertheless. This unique instrument, which embodies so many radical departures in the way of design and operation is manufactured by the EDMONSTONE COMPANY, of 105 Chambers street, New York.

So that the reader may gain a clear idea of what this instrument looks like we show herewith two illustrations. Fig. 1 clearly indicates the apparatus which performs the talking, listening and ringing functions, and Fig. 2 represents the assembled instrument in the shape of a desk telephone.

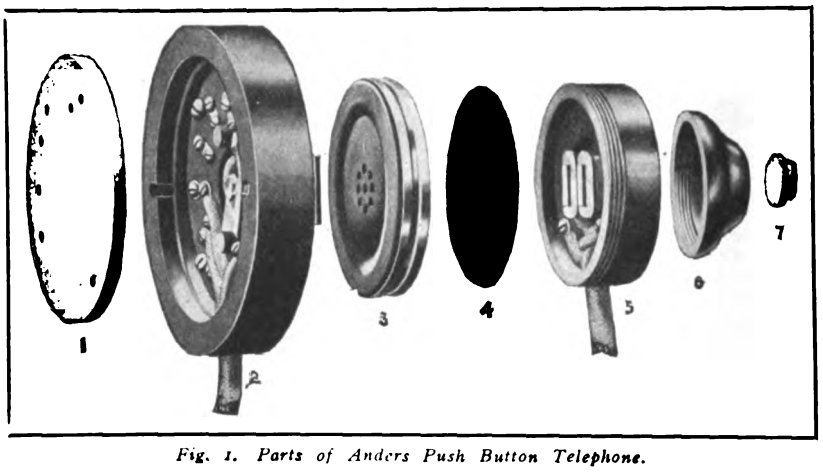

Fig. 1. Parts of Anders Push Button Telephone.

The various parts shown in Fig. 1 are as follows: 1, a fiber plate or bushing through which the wires pass before connecting to the terminals mounted on the transmitter base shown at 2. The terminals on the transmitter base include connections for the automatic switch, which is operated by the receiver. This is clearly indicated by the metal clips in Fig. 2. The receiver cap is shown at 3, and the diaphragm at 4. The receiver itself, which is made in the most approved manner with a bipolar permanent magnet and the highest grade of coils can be seen at 5. The push button cap and button 6 and 7 complete the parts.

A few words about the materials employed may be in order, as upon their quality depends a large measure of success. The transmitter is of the solid back type and consists of a self-contained holder of the button type. The granules are hard polished carbon and perfectly screened, so as to prevent odd sizes getting in and thereby tending to pack. The springs in the jack connections are of the best quality phosphor bronze and have rounded edges, designed to prevent breaking or cutting, and those used in the switch mechanism are German silver. The metal parts are all accurately machined, the utmost care being used in their selection.

This instrument is so designed as not to require readjustment with temperature changes. When the size of this little telephone is considered its most remarkable claim for originality in design is demonstrated. The diameter is but 3½ inches over all, and its extreme depth from front of push button to rear of base is 2¼ inches. Besides the type illustrated in Fig. 2, this instrument is made up in six other designs for wall and desk use, including a swinging bracket, which takes the place of the desk stand.

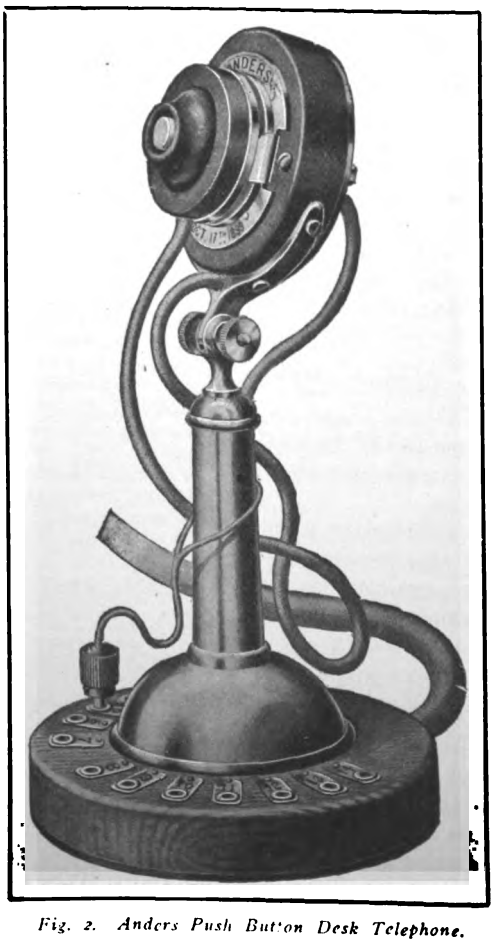

Fig. 2. Anders Push Button Desk Telephone.

The company will be pleased to furnish full particulars, and will take pleasure in mailing its descriptive booklet entitled Current Gossip to all parties interested.

THE RUMSEY AND SIKEMEIER COMPANY, of St. Louis, Mo., manufacturers and jobbers of telephone and general electrical supplies, recently issued the following circular to the Independent telephone trade:

"Believing that the telephone exchanges who realize the necessity of good telephones and switchboard apparatus, and who would prefer to procure such material from a St. Louis market fully realize such advantages to be obtained and would liberally co-operate with an industry for that purpose, we take pleasure in announcing to the patrons of the Eureka Electric Co., as well as others who have heretofore had to suffer owing to the lack of such market, that we have consummated arrangements with the Eureka Elec. Co. for the exclusive sale and handling of all their well-known instruments and other items of their manufacture in this territory. We at all times will carry in stock a full line of telephone and switchboard apparatus, and can therefore ship immediately upon receipt of all orders.

"This department will be handled in conjunction with our now well-known Electrical Supply Department, and will be represented by Mr. Herbert Rosenow, who for the past five years has been associated with the Eureka Elec. Co., and who is well acquainted and experienced in the telephone business as well as being well known to the telephone trade at large."

Mr. Rosenow, within a few days, expects to start on an extensive trip throughout the St. Louis territory, and expects to call at every telephone exchange with a complete line of samples.

THE BAIRD MANUFACTURING CO., 4 Michigan street, Chicago, has lately received an order from London for a quantity of its telephone toll counters. These little instruments are very convenient for use on switchboards for recording the

number of calls during any period and are extensively used in the United States by both Bell and Independent telephone companies.

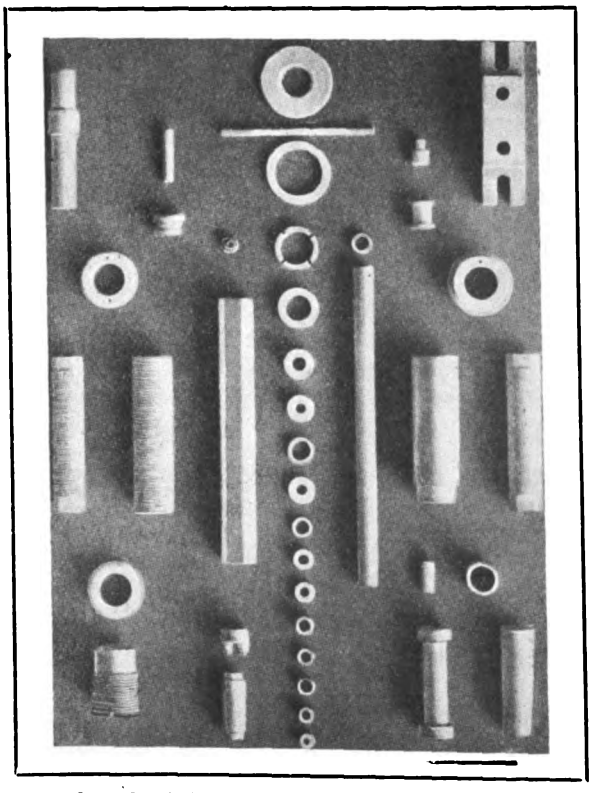
"LAVA" INSULATORS.

ONE page, showing specimens of "lava" for electrical purposes, is reproduced here from the handsome catalogue of the AMERICAN LAVA COMPANY, of Chattanooga, Tenn. They illustrate only a few of the hundreds of applications of this splendid insulating material in telephone and electrical work.

"This material," according to the catalogue, "is not, as is frequently supposed, a natural product of volcanic origin. It is the mineral Talc, which is machined in its natural condition and then baked under certain conditions of time and temperature to a condition of such extreme hardness that when properly kilned it can scarcely be cut except by diamond." Only in late years has lava been used to any extent in telephone work because of its former very high cost. The methods of its production have, however, been greatly simplified, with the result that it is about as cheap as any insulating material and more so than some of the best of them.

Lava is said to be acid proof, a better insulator and stronger than porcelain or glass. It can be turned cheaply in moderate quantities without the cost of dies or molds. It is frequently cheaper than wood, horn, fiber, compositions of rubber, etc., and is claimed to possess the desirable qualities of all of them, with none of their drawbacks. It lends itself to a variety of shapes in which mica cannot be employed.

THE AMERICAN LAVA COMPANY, Chattanooga, Tenn., will gladly receive inquiries from those interested, submit samples, estimates and other data.



Lava Insulating Specialties of American Lava Co., Chattanooga, Tenn.

W. N. MATTHEWS AND BRO., 619 Carleton Building, St. Louis, Mo., have gotten out another mailing card in the series devoted to the Stombaugh Guy Anchor. These cards have gained a great deal of praiseworthy notoriety not only from their droll composition but also from the pointed way in which the inferences are drawn with reference to this type of anchor. Mr. Entire Satisfaction draws attention to the peculiarities of the English language, using as an illustration the word "sleeper." After proving that whilst a sleeper sleeps in a sleeper running over sleepers a contingency might occur which would show there was no sleeper in the sleeper running over the sleepers under the sleeper. He continues to explain that the word "deadman" has another meaning besides the one with which it is generally associated, and that by substituting the Stombaugh anchor a man can go to sleep feeling assured that irrespective of weather conditions his line will not be disturbed and thus he can become a peaceful sleeper without having the worries of an insecurely buried deadman that is liable to move at any moment.

THE ARMOUR INSTITUTE OF TECHNOLOGY, of Chicago, Ill., is mailing a neat leaflet descriptive of its courses in telephone engineering in the evening classes during the year 1904-1905. This leaflet was prepared under the direction of Mr. G. W. Wilder, Professor in Telephony at the Armour Institute, and is particularly well illustrated with fine half-tone cuts showing views of the telephone experimental laboratories, and students at work in various departments. The leaflet will be mailed on request to anyone interested.

THE S. H. COUCH COMPANY, 156 Pearl street, Boston, Mass., has gotten up some advertising matter which is well worth the attention of all telephone managers. One of the most valuable articles in connection with inside wiring is the staple. This firm has for sale the Blake insulated staple which possesses some important features. First, its insulation. This is secured by means of a double fiber cap which is securely attached and at the same time affords perfect insulation. Then the head is made square, thus affording a good surface for driving purposes. These staples are made in two sizes, one ¾-inch for general use and the other ½-inch in length for use in hard wood. The price is but slightly more than for the ordinary kind and its advantages are so obvious as to counterweigh all considerations from the standpoint of price. The company will be pleased to furnish full particulars upon request.

THE AMERICAN STEEL AND WIRE CO., of Chicago, is circulating a booklet describing Sulphate of Iron (copperas) and its uses. By immersing lumber, timbers, posts, railroad ties, etc., in a hot solution of sulphate of iron, every part of the wood treated is impregnated, chemical changes take place, solidifying the core and fiber, thereby preventing decay and preserving the life of the wood tenfold. This process is approved by the German Government, and railroad ties, telegraph posts, etc., in Germany are now treated in this manner. It is more efficient than the ordinary treatment for preservation of wood, which treats the outside of the wood only and does not reach the interior core or fiber. By this same treatment wood can be rendered practically fire-proof. The company will furnish detailed information upon request.

THE CENTRAL ELECTRIC COMPANY, of Chicago, is taking additional floor space as a first preparation to making a more active campaign for business than in the past.

THE CONN. TEL. & ELEC. CO., INC., of Meriden, Conn., reports large sales of its 4-party selective system. This new system will interest all exchanges which are endeavoring to have their systems up to date. Its new biased ringer and master key are made

THE MORRIS HARD FIBRE CLEAT

"Style A."
(Exact Size.)

For Twin or Parallel Wires.
Price $4.30 per 1000.

ONE screw is all that's necessary to fasten the **Morris Hard Fibre Cleat** for twisted pair and parallel wiring. Two screws are required with Wooden or Porcelain Cleats. This makes a great difference when 500 or 000 cleats are used in a day. It means a saving of half the time of the installer. It also means that from 500 to 1000 less screws will be used.

Style "C."
(Exact Size.)

For Corners.
Price $4.00 per 1000.

THEY **save time. They save money.** You are willing to do both. Then we should have your order now. The **Morris Hard Fibre Cleats** never break or wear out. They are Perfect Insulators. They **cost less** than Porcelain and outwear them twice over. About the same as wooden cleats, and outwear them ten times They are **smaller** and **neater** than all others.

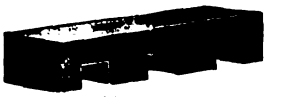
THIS being so, are not **The Morris Hard Fibre Cleats** worth using? Hundreds of Telephone Companies, both Independent and Bell, have already adopted them as standard for inside wiring.

Style "B."
(Exact Size.)

For Twisted Pair.
Price $4.50 per 1000.

THEY solve all inside wiring problems. Have you tried them? If not write to-day. Made in three colors, red, gray and black. Specify color, otherwise we will send red.

"Style D."
(Exact Size.)



For Three Wires.
Price $6.50 per 1000.

We Gladly Mail Free Samples on Request.

up in a thoroughly practical manner and will please managers who are looking for apparatus of high quality.

A TOLL CONNECTION REMINDER.

A NEW and novel idea for presenting to Independent telephone subscribers the fact that the Independent exchanges are connected by long-distance toll lines has been put into practice by the Inter-Ocean Telephone and Telegraph Company, of Buffalo, N. Y.

The idea consists of placing a neat and attractive celluloid sign immediately back of the mouthpiece on the transmitter. This reminder is before the subscriber every time he uses his telephone. The device is illustrated herewith, showing how it is placed on the transmitter behind the mouthpiece

This sign can be used universally by Independent telephone companies. Samples, together with other information, can be obtained by addressing the Century Telephone Construction Company, Buffalo, N. Y., the originators of the idea.

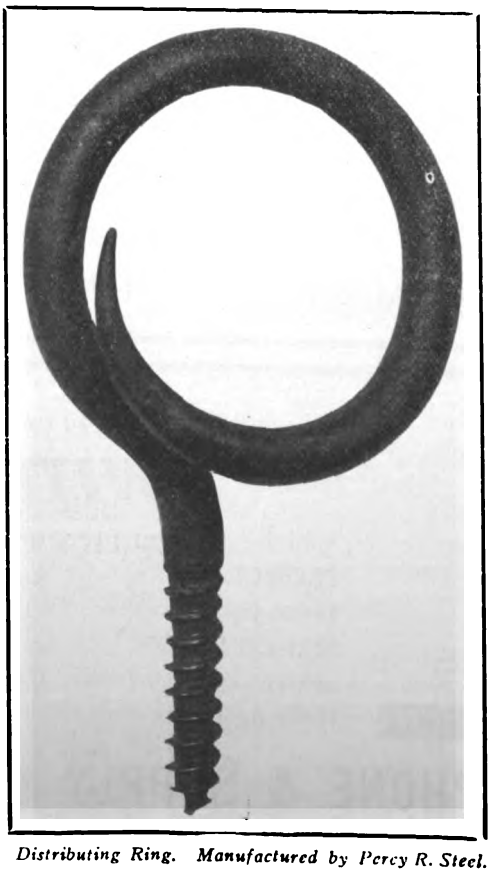
Toll Connection Reminder. Manufactured by the Century Telephone Construction Co.

M. LANZ & SONS, Pittsburg, Pa., manufacturers of galvanized and plain pole line hardware, have recently completed additions and improvements which enable them to produce pressed steel and malleable iron guy clamps, cross arm braces, bolts, washers, fetter drive lag screws, pole steps, pole seats, guy rods, rock anchors, thimbles, angle steel cross arms, etc., in greater quantities and at lower prices than heretofore, at the same time maintaining the high standard of quality for which their product is noted. They do their own galvanizing by the hot process, and use prime western spelter only, so that they have no difficulty in guaranteeing their product to stand the most rigid tests. Their factories are located amid the iron and steel mills, and their siding connects with all the railroads entering Pittsburg. They have been manufacturing bolts, hinges, etc., for the past forty years; began the manufacture of pole line hardware about fifteen years ago, at which time they erected their galvanizing plant. In addition to the articles mentioned above, they are prepared to furnish miscellaneous hardware, covering the other iron and steel articles used in pole line construction. They quote lower prices on specifications, giving quantities, sizes, etc., and they believe it to the advantage of prospective buyers to send them a complete set of blue prints, assuring them that all inquiries and orders will have the most careful and prompt attention.

THE DEAN ELECTRIC CO., Elyria, Ohio, has issued a booklet entitled "Transmitters and Receivers," which is the first of a series that will be distributed from time to time describing Dean telephone apparatus. Diagrams illustrating three different types of transmitters are shown, viz., Bell solid back, Reverse type solid back and Dean solid back. Attention is called to the Dean transmitter and deductions are made which claim superiority in design over the others. Among other important points in its construction and operation are simplicity, self-adjustment and inability to pack. The Dean receiver embodies all the most advanced ideas in design and has many points of advantage over others. Especial attention is drawn to the adjustment which is made irrespective of the shell, and also to the terminals for receiver cords which will grip any style of tip or the tinsel ends.

A NEW DISTRIBUTING RING.

THE items charged to construction of a system which represent the greatest outlay are those incidental to the building and maintenance of the line plant. It is, therefore, very evident that the manager who wants to make a good showing at the end of the year must be ever on the alert for new wrinkles which will tend to reduce this expense. Percy R. Steel, of 609 Commerce street, Philadelphia, Pa., has placed upon the market a type of distributing ring which has some points of merit worthy of consideration of the exchange manager. Although the general design is not new, yet it has some advantages not met with in others.



Distributing Ring. Manufactured by Percy R. Steel.

By reference to the illustration, the length of the screw will be noticed. This enables it to be used in places where the shorter length screw rings would not hold. For instance, in fastening to weather-worn woodwork the distance it can be driven in will insure a secure hold. The pointed tip of the ring allows a wire to be easily slipped through, thus saving time which, however small, in an individual case, becomes cumulative in extent where there are any number to be used. Besides possessing these advantages, it is made of a high grade of iron and is insulated with the best quality of enamel suitable for the purpose, thus adding high insulating qualities to its other points of superiority. Besides this specialty the firm manufactures all sorts of hardware for this class of work and each piece has an individuality that places it at the very top of the particular line which it represents.

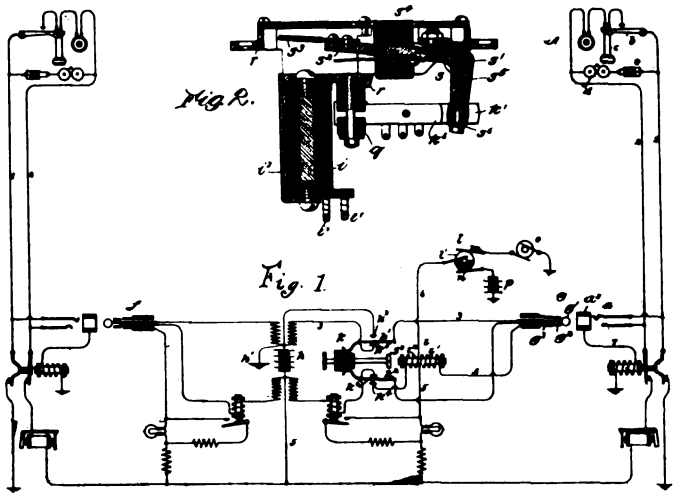
TELEPHONE PATENTS

MACHINE RINGING KEY.

W. W. Dean, Chicago, Ill., patents (No. 771,897) an improved automatic ringing key and assigns to Western Electric Company. The object of this invention is to provide an improved automatic ringing key which after being actuated continues to ring the subscriber until the latter removes his receiver. The circuit of the apparatus is illustrated in Fig. 1 and the general mechanism in Fig. 2. The operation of the system is as follows:

When the operator inserts plug *g* into spring jack *a*, a local circuit from battery *h* is completed from ground through conductor *5*, winding *i'* of the sticking magnet to shank *g3* of the plug and thence to the test ring of spring jack *a*, which is connected to ground by conductor *7* including the cut-off relay. The magnet *i* is energized and when the operator depresses the push



button of the ringing key, the armature *s3* sticks to the pole of the magnet, maintaining the key in the depressed position. The key connects the segment *l'* of the commutator *l* with the spring *k2* and grounds the other spring *k'* which is connected to the tip of the plug. As the commutator rotates, alternating current from the generator is intermittently applied and sent over the line. This alternating current passes through the magnet *i*, but it is so weakened by the high resistance of the bell, that its effect is not sufficient to unlock the key. When the subscriber removes the receiver, a low resistance path is provided which passing through the winding *i2* in the opposite direction to the current *i'*, neutralizes the magnet and releases the key.

TELEPHONE RELAY.

H. Carbonelle, of Uccle, near Brussels, Belgium, patents (No. 772,213) an improved telephone relay. This invention relates to an improved telephone relay. The inventor accomplishes his object by providing a kind of alternating current generator, having alternations so rapid as to be imperceptible as sound and the operation of this generator is arranged to re-enforce the sound waves which are set up by the transmitter.

IMPROVED SUPPORTING BRACKET FOR TELEPHONE SUBSTATIONS.

H. A. Barnes and N. E. Showacre, of Baltimore, Md., patent (No. 772,773), an improved supporting bracket for telephone substations. The object of this invention is to provide an adjustable bracket so arranged that it may sustain the transmitter and receiver in certain fixed positions in reference to each other so that they may be convenient to the lips and the ears of the users. The inventor provides two arms which are independently adjustable with reference to each other in both vertical and horizontal planes. To the ends of these arms, the receiver and transmittter are respectively attached.

ANTISEPTIC MOUTHPIECE.

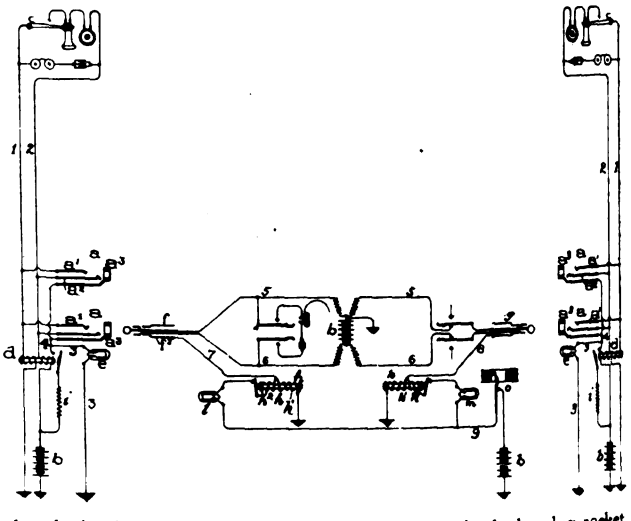
Mr. C. D. Wright, of Chicago, Ill., patents (No. 770,410). The inventor provides a paper mouthpiece for the voice trumpet of a transmitter, which is moulded in such a way as to spring over the circumference of the transmitter mouthpiece and thus be retained in place.

TOLL COUNTER FOR AUTOMATIC SWITCHBOARDS.

J. Erickson, of Chicago, Ill., patents (No. 772,459) an improved toll counter for automatic switchboards, and assigns to the Strowger Automatic Telephone Exchange. The object of this invention is to provide a toll counter which is adapted for use upon automatic switchboards. The inventor provides the usual set of numbering wheels for registering the number of calls, but in order to make the device operative with automatic switchboards, the register is so arranged that it requires several impulses instead of one to actuate it, and thus if more or less than the required number of impulses are given, no register is made.

IMPROVED SUPERVISORY SIGNALING.

Mr. F. R. McBerty, of Evanston, Ill., patents (No. 772,889) an improved supervisory signal, and assigns to the Western Electric Company. The object of this invention is to provide an improved supervisory signal for common battery switchboards. It is illustrated in the accompanying drawing. The operation of this circuit is as follows: When the receiver is removed, current flows through line relay *d*, closes local circuit *3* and illuminates line signal *e*, and puts battery on rings of spring jacks *b* by conductor *4*, thus providing a test. The operator inserts plug *f*, establishing the shunt *7*, *4* about the line signal lamp and extinguishing it. Magnet *h* is excited by current through winding *h'* cutting out the supervisory signal *h*. After learning the desired number, the operator inserts the calling plug *g* into the jack of



the desired subscriber. When this plug is raised, the plug socket switch *o* is closed, supplying battery to conductor *9* and when the plug is inserted in the spring jack of the called line, the circuit *4 3* is established. Until the party answers, the contacts of his line relay are open. Current flows from conductor *9* through supervisory lamp *m* by way of the armature and back contact of magnet *k* through both windings k^1 k^2 in the series. As these windings are differential and balanced, the supervisory is not extinguished. When the called subscriber removes his receiver the relay *d* is excited and increased current flows through winding *k'*, magnet *k* is unbalanced, cutting off the supervisory signal *m*,

THE WEEK'S MESSAGES

FINANCIAL.

ROCHESTER, IND.—The Rochester Telephone Company is building a line to Kewanna.

MARSHALL, MICH.—The Marshall Telephone Company will increase its capital stock from $15,000 to $50,000.

JASPER, MINN.—The Jasper Telephone Company has been purchased by the Enterprise Telephone Company.

STILLWATER, MINN.—It is proposed to establish a police telephone system in this city

NEW YORK, N. Y.—Julius G. Kramer has been appointed receiver for the Rosemont Electric Transmitter Company of 207 Green street.

BURTON, OHIO.—The Burton Telephone Company has increased its capital stock from $15,000 to $25,000.

LECK HILL, PA.—D. S. Leitzel and E. C. Tschopp have guaranteed the required amount of money necessary to extend the system of the Mahonoy & Mahantongo Telephone Company from Greenbrier to Leck Hill.

RACINE, WIS.—The directors of the Citizens' Telephone Company will expend $30,000 in improvements, consisting of a modern exchange.

FRANCHISES.

OCEAN PARK, CAL.—The Ocean Park city trustees will readvertise the telephone franchise.

MACKINAW, ILL.—The Farmers' Telephone System of Hopedale has applied for a franchise in this village.

ESTHERVILLE, IA.—The Emmet County Telephone Company has been granted a franchise in this city.

BANGOR, ME.—A franchise has been granted the Bangor Automatic Telephone Company.

GREENVILLE, ME.—The Moosehead Lake Telephone Company has been granted permission to construct and maintain a telephone line along the right of way of the Canadian Pacific Telephone Company, from this place to Hobb Station, in Somerset county.

GIRARD, OHIO.—S. C. Thayer has asked the Council to extend the terms of his telephone franchise until spring.

COOPERSBURG, PA.—F. S. Lewis, manager of the Lehigh Telephone Company, has applied to the Town Council for a franchise in this city.

DALLAS, TEXAS.—F. B. McElroy, who for some time has been endeavoring to secure an Independent telephone franchise in Dallas, has stated that he would contribute the funds necessary for holding a special election to decide whether the voters of this city desire an Independent telephone system. If the voters should decide favorable, there is very little doubt that the Council would grant such a franchise.

MONTPELIER, VT.—The Orange County Telephone Company has been granted a franchise to extend its system in this city.

COMBINATIONS.

SAYBROOK, ILL.—Robert Means has purchased the Saybrook Telephone Company, and Howard Means, his son, will take possession. The new company will be H. R. Means & Co.

WAYNESVILLE, ILL.—The Farm & City Telephone Company is reported to have purchased the J. M. Jeffrey line.

RICHMOND, IND.—The Brownsville & College Point Telephone Companies have united their lines and established an exchange at Liberty.

OAKVILLE, IA.—L. S. Erbes will purchase the Oakville Telephone Exchange. Mr. Erbes' address is St. Paul, Minn.

INTERNATIONAL TELEPHONE MANUFACTURING COMPANY
HARRISON AND CLINTON STREETS - - - - - - - CHICAGO, U. S. A.

Digitized by Google

ALBANY, N. Y. The Independent Union Telephone Company of Buffalo, has changed its head office to Albany.

STITTVILLE, N. Y.—A farmers' telephone line has been built from Camroden to the office of E. D. Jones of the village. A number of farmers have already been connected.

LONDON, ONT.—The city has installed an automatic telephone fire alarm system.

OIL CITY, PA.—The Petroleum Telephone Company's Exchange was recently damaged by fire to the extent of $20,000.

SEATTLE, WASHINGTON.—The City Council has passed an ordinance for a new twelve-circuit repeater for the improvement of the fire alarm service.

FON-DU-LAC, WIS.—The local telephone company expects to have its new switchboard in operation by December 1st.

UNDERGROUND.

MADRAS, INDIA.—J. B. Gibbons, a representative of the Oriental Telephone & Telegraph Company, a corporation of London, England, and operating telephone systems in India and other Asiatic countries, recently surveyed the telephone systems of the Madras Presidency, with a view to installing underground cable systems.

COLORADO CITY, COL.—The El Paso Telephone Company will construct about twelve blocks of underground cable system in this city.

AUBURN, ILL.—The Interstate Telephone Company has been granted a franchise to construct an underground system in this city.

PEORIA, ILL.—The city is considering placing its fire alarm and police wires underground.

MEXICO CITY, MEXICO.—The Mexican Telephone Company will install an underground conduit system.

NILES, MICH.—The South Bend Home Telephone Company contemplates installing an underground system in this city.

OBITUARY

JUDGE J. M. THOMAS, the first president of the National Telephone Association and one of the pioneers in the Independent field, died at his home at Irvington, N. Y.

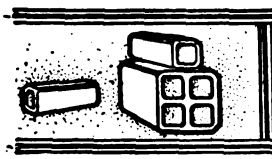
ELECTIONS.

WINDSOR, ONT., CAN.—The directors of the recently incorporated Ontario Independent Telephone Company are: C. W. Taylor, J. R. Brooks, J. A. McRae, P. F. Chisley and A. D. Prosser.

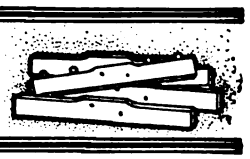
COLUMBIA CITY, IND.—The Whitley County Telephone Company elected the following officers: S. J. Peabody, president; J. E. Remington, vice-president; W. Magley, secretary and treasurer.

HARRIS, OHIO.—Levias Glassburn, of Bedwell, has been elected president of Telephone Line No. 10.

THURMAN, OHIO.—M. J. Williams has been elected secretary of No. 1 Moriah Telephone Company in place of F. W. Evans.



New Construction in the Field



GAINESVILLE, FLA.—The East Florida Telephone Company will extend its system this winter.

SOUTH WHITLEY, IND.—The Farmers' Mutual Telephone Company has seventy-eight telephones in operation, and contemplates making a number of extensions.

NEW HARTFORD, IA.—The Farmers' Telephone Company is replacing all its poles with ones thirty-five feet in length, on account of increased business.

MANHATTAN, KAS.—The Riley telephone line will be extended in the near future.

WAYNESVILLE, KY.—The Fayette Home Telephone Company is constructing a line from Lexington to this city, where it will connect with the line of the United States Telephone Company.

DIXMONT, ME.—The Unity Telephone Company will extend its line this winter.

RIPLEY, ME.—Dr. Moulton will extend his telephone line this fall.

SABATTUS, ME. The North Eastern Telephone Company, it is reported, will build a telephone system in this village.

HARTLAND, MINN.—The telephone line is to be extended North and West.

LESTER PRAIRIE, MINN.—A new forty-five-drop switchboard has been placed in the local telephone office.

LE SUEUR CENTER, MINN.—Work will soon be commenced on the construction of the Cleveland telephone line.

MELROSE, MINN.—The Melrose Telephone Company has moved its exchange into larger quarters, and has made several extensions to its system on account of growing business.

REDWING, MINN.—Headquarters have been chosen for the new telephone company, of which D. M. Neil is the local manager. Arrangements have been about completed for the construction of the plant.

SPRINGFIELD, MINN.—The telephone line from here to Confrey is completed.

WHITE BEAR LAKE, MINN.—The Farmers' Telephone line will be constructed at once.

COLUMBUS, MISS.—The Citizens' Long Distance Telephone & Telegraph Company will undertake extensive improvements to the telephone system in the near future.

LIMERICK, MO.—The Ossipee Valley Telephone Company has extended its lines to South Limington.

KALISPELL, MONT.—The Kalispell Water & Electric Company has decided to construct a telephone line from here to the Northern Pacific Railroad.

DIXON, NEB.—A movement is on foot to establish a local telephone system.

HUMBOLDT, NEB.—The Humboldt Telephone Company is laying cables to accommodate rural patrons.

SEWARD NEB.—The Seward County Telephone Company will install a system in this city at once.

HUDSON, N. H.—A. S. Andrews and H. A. Andrews are building a telephone line in Londonderry.

TILTON, N. H.—The Citizens' Telephone Company is stringing new lines and putting in many new telephones at Northfield Center.

ARGYLE, N. Y.—The Commercial Union Telephone Company has erected its line and expects to have it in operation shortly.

BARTON, N. Y.—The Ross Hill Barton Independent Telephone Company, at a recent meeting, appointed a construction committee, and the building of lines will be commenced at once.

ENDICOTT, N. Y.—The York State Telephone Company will establish an exchange in this village.

HAMDEN, N. Y.—The Launt Hollow Telephone Company is extending a new line to Walton. It has been planned to extend the line in the spring from Walton to Rock Raft, where it will connect with the Cannonsville-Deposit line. The company at present has its headquarters in Hamden, but it is likely that the main office will be moved to Delhi in the spring. Ralph Anderson, of Hamden, is president of the company.

LESTER, N. Y.—The recently incorporated Lester Telephone Company will build lines on the north to Hudson, southeast to the State line, and northwest to Binghamton.

CANDO, N. D.—The wiring of the telephone extension north of St. John is being completed as fast as possible. Connection with Considine has been established.

GRANVILLE, N. D.—An Independent telephone line will be established between this village and Mohull.

JAMESTOWN, N. D.—The new telephone line to Buchanan is expected to be in operation in a few days.

WAHPETON, N. D.—The Tri-State Telephone Company will extend its system in this vicinity.

COLUMBUS, OHIO.—The New Long Distance Telephone Company of Indianapolis, will build a toll line from this city to Hope.

DANVILLE, PA.—C. V. Amerman is contemplating establishing a Rural telephone system in this vicinity.

GEIGERTON, PA.—The Conestoga Telephone Company will run a new line from this place to Plowville.

HARRISBURG, PA.—The New Albany Telephone Company will build telephone line from New Era, Bradford county, to Evergreen and New Albany, and also from Overton, Bradford county, to Campbellsville, Eldredsville, Estella and Forksville, Sullivan county. The directors are R. S. Wilcox, R. Decker and S. D. Sterigere, of New Albany, and others.

HONESDALE, PA.—The Stroudsburg & Bushkill Telephone Company will extend its system to Portland.

MARTINSBURG, PA.—The Roaring Springs Telephone Company will build a line from this place to Williamsburg.

NEW HOLLAND, PA.—The Enterprise Telephone & Telegraph Company will extend its line in the near future, and make connections with the Conestoga Rural Telephone Company, operating in the vicinity of Morgantown.

SCRANTON, PA.—The Northeastern Pennsylvania Telephone Company is extending its lines throughout this vicinity.

BOONSTEEL, S. DAK.—Work is in progress on the construction of a line from here to the new town of Gregory.

DEADWOOD, S. DAK.—The Home Telephone Company will overhaul its system and make several improvements.

HUDSON, S. D.—The Hudson Telephone Company will extend a branch line across the State line into Iowa.

IRENE, S. D.—The Independent line is built as far as Volin and will be run into Irene in the near future.

PIERRE, S. D.—Work has been commenced on the Cheyenne River reservation. Two lines are to be built, one from White Horse Camp and the other from Cherry Creek.

CREWE, VA.—It is stated that the rural telephone line being built through Nottoway and adjoining counties will come into Crewe and connect at the present central office with the local line.

ST. JOHNSBURY, VT.—The Citizens' Telephone Company is extending its line to West Danville.

BELMONT, W. VA.—The Belmont Telephone Company has recently installed a new cable line.

BENWOOD, W. VA.—The National Telephone Company is building a number of new lines, including one to Sherrard.

CADOTT, WIS.—Mr. Ole Jenson, owner of the Cadott Telephone Company, will extend the system from Stanley to Thorp, and build other rural lines.

SPRING VALLEY, WIS.—During the next year a new rural telephone line will be built by the farmers in this vicinity from this place to Menominee, and another line to Glenwood.

APPLETON, WIS.—The Fox River Valley Telephone Company has completed its new line to Hortonville. It is the intention of the company to run lines through different parts of the county.

WHEELING, W. VA.—The Belmont Telephone Company has extended its lines and it is now possible to reach Steubenville. They will make connections with East Liverpool in a short time.

BELMONT, W. VA.—The Belmont Telephone Company is extending its lines with aerial cable.

Two Things Every Telephone Man Needs

They are the American Telephone Journal (published weekly), a year's subscription for $1.00, and a copy of the new and revised edition of "The A. B. C. of the Telephone"; a practical book for telephone men. This new edition has been brought thoroughly up-to-date, and sells for $1.00. By a special arrangement we will send a copy of the "A. B. C." and give a year's subscription to the American Telephone Journal—both for $1.50.

THE AMERICAN TELEPHONE JOURNAL

We are Justly Proud

of the new department "In the Manufacturing Field." It has been accorded an enthusiastic reception by our readers.

The manufacturers and supply dealers have been quick to appreciate its advantages in enabling them to announce new devices and apparatus.

The matter contained in this department apparently is just what our readers want. It keeps them posted on appliance development. This is the tenor of hundreds of letters received in the past three weeks.

We would like to hear from all our readers regarding the new department.

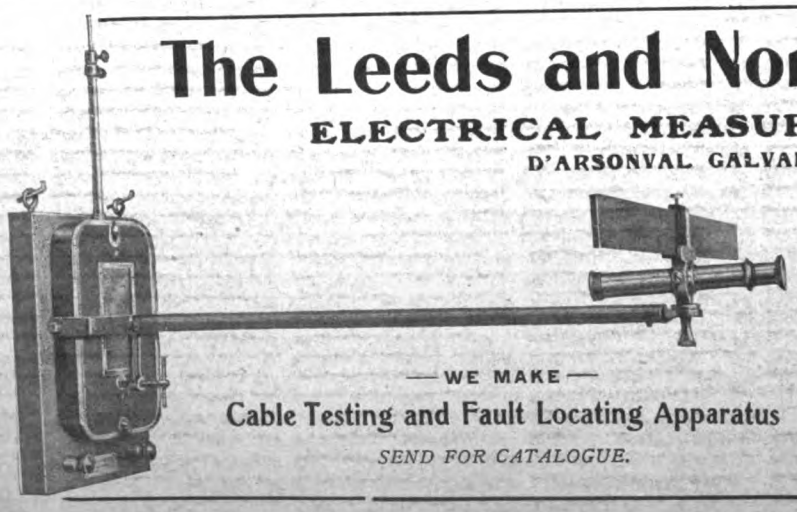
ELECTRICAL MEASURING INSTRUMENTS

D'ARSONVAL GALVANOMETER TYPE P.



—WE MAKE—

Cable Testing and Fault Locating Apparatus

SEND FOR CATALOGUE.

Stimulated by the large demand for a good Galvanometer at a reasonable price, we have gotten out this instrument. It is well made, of finished workmanship, pleasing appearance and excellent working qualities. Its low price is due to good design, careful manufacture and production in quantity, and in no detail to poor material or slighted workmanship. It has the following desirable features: Simplicity of construction, attractive appearance, the moving system always entirely visible, a proportional scale, a damped system and quick working, strong suspensions that allow no zero shift, ample coil clearance and a sensibility that is ample for all ordinary electrical measurements and many precision measurements.

THE TELEPHONE ON BOARD WARSHIPS

By Dr. Alfred Gradenwitz.

THE telephone is being more and more widely adopted for military purposes, and is assuming an important role, especially on board warships. Now, whereas for many other applications the existing types of telephone had only to be slightly modified, a thorough alteration was necessary to adapt them for marine purposes, and many interesting new features had to be developed by the inventive skill of the engineers who took charge of the matter.

The acoustic or speaking tube which formerly was exclusively in use for transmitting commands on board war vessels could not be replaced by telephones before the telephonic transmission of sounds was rendered so intense that orders arriving could be received, even if the listener were three feet or more from the apparatus. This result obtained, the adoption of telephones offered the advantage over acoustic tubes of being applicable for longer distances, allowing conversation to be transmitted to several receiving stations simultaneously, and finally of being independent of the relative situation of the various telephonic posts.

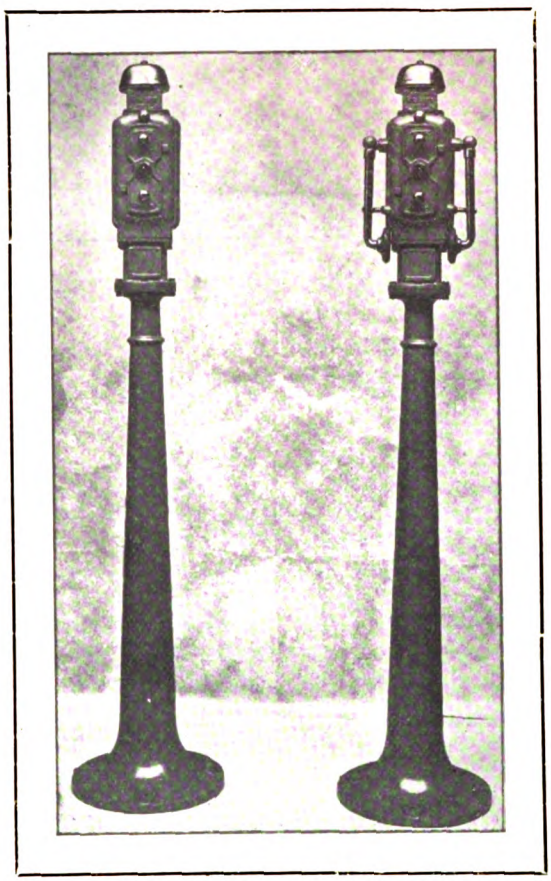

Fig. 1. Marine Telephones for German Warships.

In telephone plants on board ships the lines start from one central station, leading radially to the various telephones distributed throughout the vessel. Now, instead of utilizing switches in the central station in order to talk to any one of the substations, the circuits of the latter should be kept permanently closed, thus every telephone line terminating in the central station should have its own individual apparatus. The central commanding place and the conning tower being protected by armored plates are generally used as telephone central stations, both being so connected with one another by inserting switches as to allow the telephone loops being used from either of them.

In addition to telephone lines connecting two telephones, the necessities of ship service, and especially the control of the artillery fire, entail the necessity of several substations communicating simultaneously with the commanding central.

Telephones on board ship are being used for the following purposes:

1. For transmitting orders relative to the course of the ship and its control.

2. As artillery telephones, leading from the commanding central to the various gun positions.

3. Finally, for manœuvering the ship torpedoes.

The firm of Mix & Genest, of Berlin, Germany, has devoted especial attention to the development of telephones for military purposes, and has fitted a large number of men-of-war with their apparatus. The microphone used by this firm embodies a further development of the short and long-distance transmitter used by the Imperial Postal Department in Germany, that allows of a considerable acoustic intensity. This microphone consists of a contact piece provided with annular grooves, in front of which the carbon is located. The grooves are filled up with carbon powder, while a strip of cloth placed against the back contact piece and stuck at the same time to the carbon plates, effects the lateral closure of the grain chamber. As the diaphragm is set vibrating, the carbon powder is submitted to alternative compressions and expansions, while the soft cloth strip and a central wool brush conveniently dampen the oscillations.

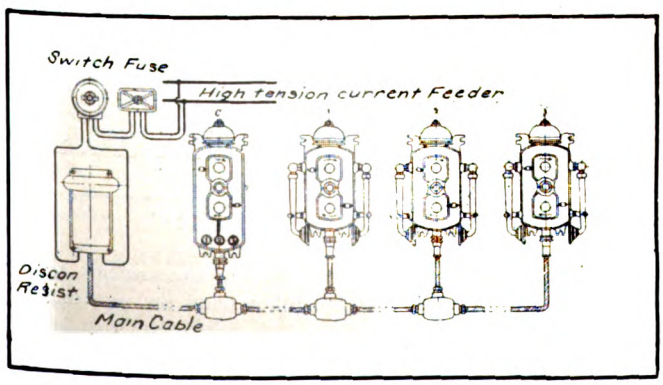

Fig. 2. Connections of Marine Type Telephone.

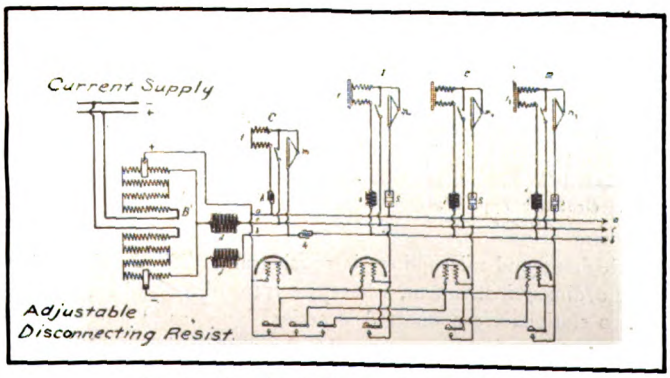

Fig. 3. Circuits of Marine Type Telephone.

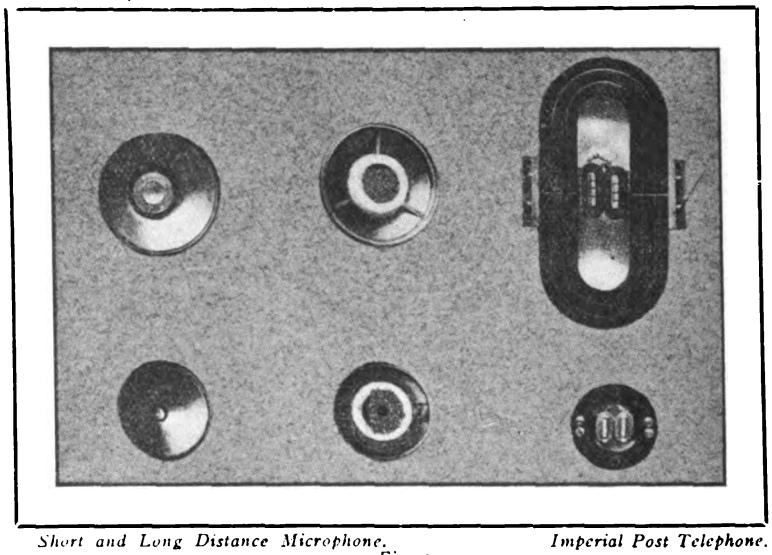
Digitized by Google

This microphone has been further developed into the so-called Stentor microphone, intended for high tension operation, by increasing all dimensions and transforming the grain chamber. The latter is filled with a considerable amount of big grains of hard carbon, the lateral closing being effected by a fireproof mica ring, surrounded by a damping ring made of fine felt. As the Stentor microphones are exposed to large currents, slight arcs are frequently produced, which could set the damping device on fire but for the protective mica ring. The diaphragm is of aluminum, to which a small carbon plate is riveted so secured to the curled edge of the capsule as to prevent any strain. The normal current of the Stentor microphone is 20 times greater than that of the short- and long-distance microphone of the Imperial Postal Department, while its stability is satisfactory because of the large amount of carbon granules it contains. The microphone obtained by this modification allows of a far greater acoustic intensity, while the clearness is only slightly impaired.

Stentor Microphone. *Stentor Telephone.*



Short and Long Distance Microphone. *Imperial Post Telephone.*

Fig. 4.

In a similar way the loud-speaking telephone combined with the microphone has been transformed by increasing the magnetic field. In Fig. 4 is shown the system of a loud-speaking Stentor telephone, comprising 6 magnets, compared with the German postal telephone, both being represented in their proper dimensions.

These modifications result in increased acoustic effects, but the increased efficiency of which is lost, however, to a great extent as soon as the telephone and microphone are enclosed in a wood or metal box. Similar disturbances are noted when the microphone is submitted to overloads, or to external electric effects. When machine current is used in place of that desired from accumulators to operate the microphone these disturbances are particularly noticeable, since the current from a direct-current dynamo is by no means perfectly continuous, owing to the fluctuations due to the short-circuiting and opening of the armature coils at the commutator of the machine.

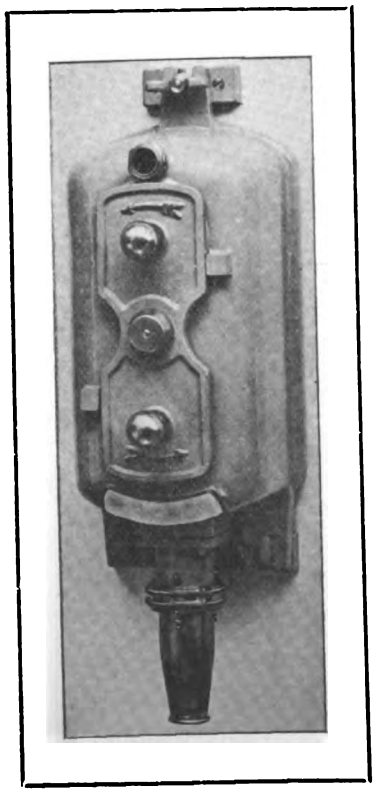


Fig. 5. Ordinary Type Marine Instrument.

Now the current may be smoothed out, as it were, for microphone operation by means of reaction coils, which dampen the fluctuations, and by connecting a condenser parallel these fluctuations can be further reduced.

The mutual connection of the telephone and microphone is considerably different from that of the ordinary instrument, where the transmitter and receiver of the two stations are connected in series. Now, as at any moment only one station is being spoken to, the other being used for listening, all others will always be out of service, hampering the full development of the alternate current waves. This is obviated in the loud-speaking telephone by the three conductor systems of Fig. 7, where the principle of inserting in each closed circuit only one transmitter with a receiver has been carried out.

The diagram of connections for stationary loud-speaking multiple telephones, as developed by the Mix & Genest firm, is simple, being based on the fact that every microphone circuit of the above kind can generate sounds of such energy as to be susceptible of electrical distribution over a number of parallel branches, if a sufficiently loud-speaking equipment is used.

As seen from Figs. 2 and 3, the central station is connected with the different secondary station exclusively by three conductors (*a b c*), every receiving station, and accordingly the central station itself being fitted only with one microphone and telephone. Between *a* and *c* are placed in parallel the microphones *r*, p_1, m_1, etc., of the various secondary stations, as well as the telephone *t* of the central station. Between *b* and *c* in parallel to one another is the microphone *m* of the central station *C* and the telephones, t^1, t^2, t^3, etc., of the secondary stations, as shown. This arrangement imitates the familiar three-conductor systems. In the latter the whole of the battery current, including its fluctuations produced by speaking against the microphone membrane, traverses both the microphone and the telephone connected in series as well as working battery. In the present arrangement a separation is made so that the continuous working current traverse the microphone, while the telephones placed in parallel are prevented from receiving the continuous current by the condensers *k*. This results in the fluctuations superposed on the continuous current being led through the condensers *k* and the telephones *t*, t^1, t^2, etc., while on the other hand reaction coils *d* will prevent a possible diversion through the current source *B*. The reaction coils thus prevent on one side any disturbing fluctuations of the machine current against the telephone and on the other hand the weakening of speaking current oscillations on a path other than that leading through the telephone. The speaking energy is thus exclusively supplied to the hearing telephone, the undiminished intensity en-

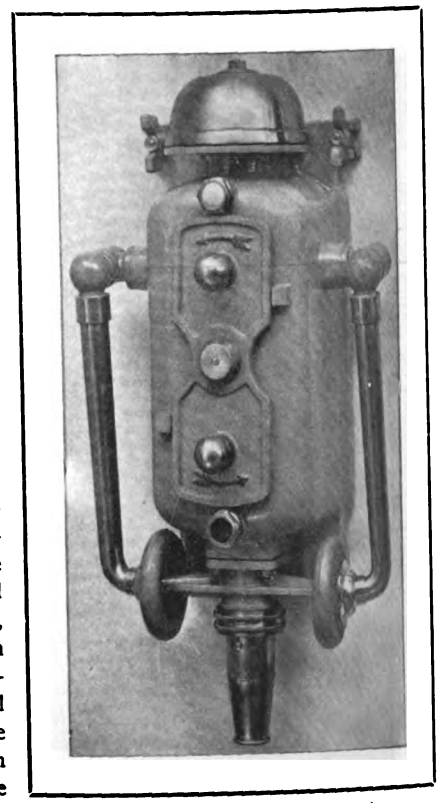

Fig. 6. Instrument for Noisy Locations.

Digitized by Google

suring an especially pure and intense transmission of conversations.

The objection could be raised that the various stations are more dependent on one another than in the usual method, so that in the case of a station being destroyed by the fire of the enemy, the operation of the remaining stations would also be impaired. In order to exclude this, the main cable (*a b c*) common to all the stations, together with its accessories, is effectively protected by armored plates, the secondary stations are first exposed to destruction. The fuses *s* and the small inductive resistances *i* have therefore been inserted into the branch circuits of the latter. Should any

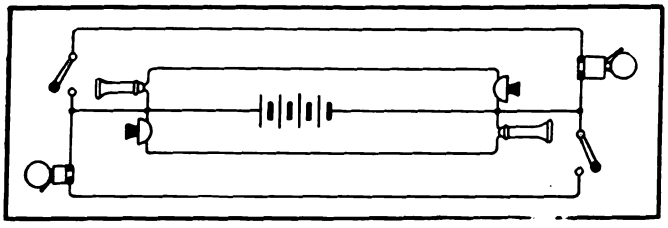

Fig. 7. Three Wire Circuit of German Marine Telephone.

branch circuit loop be short-circuited by the effect of the fire a weakening of the microphone-feeding current through the same would be prevented by the fuses *s*, while on the other hand, a diminution of the speaking current through the short-circuit is prevented by the resistance coils *i*. Experiment has shown this arrangement to be very effective, doing away with the mutual dependency of the various stations.

The calling apparatus, with its conductors, should be electrically independent of those intended for speaking. The arrangement provided for this will be readily understood from the diagram, and is not different from the usual scheme, apart from independence of the conductors. The central station may call any of the secondary stations, while any one of the latter is able to call the former without signalling any station not concerned.

As regards the constructive design of the apparatus a watertight enclosure, extreme solidity of the casings and movable portions ensuring the safety of the microphone and telephone against mechanical injury, and the safeguarding of the conductors are the most essential points to be considered. The instruments represented in Figs. 5, 6 and 7 show some different designs of marine telephones, those in Fig. 6 with lateral hearing tubes being intended for noisy rooms. The locking shield seen in front is common to all, being turned into a horizontal position during use. This shield is intended on one hand to protect in the state of rest both the telephone (upper opening) and microphone (lower opening) in the casing; on the other hand, it switches in the microphone into the circuit; and, finally, by rotating the microphone capsule immediately before speaking, the granular carbon is stirred violently, thus ensuring a permanent, satisfactory operation of the microphone. The instruments may be fitted also with glow lamps serving as a signal of a preceding call.

HINTS ON RURAL CONSTRUCTION

ARTICLE I.—(CONTINUED).

BY P. A. PRICE.

ALWAYS keep a record of the corners in estimating the number of poles, so that extra poles can be left there for guying purposes. Short poles will answer for these "guy stubs," as they are called, but they must be long enough to plant firmly and give the guy wire good clearance over the roadway. Heavier poles for the line are desirable for corners, and also to be placed on each side of creeks which are to spanned by the line. If the waterway be very wide, say two spans, the poles should be double armed on each bank. When the route crosses a railroad, permission must be obtained from the railroad company to cross their

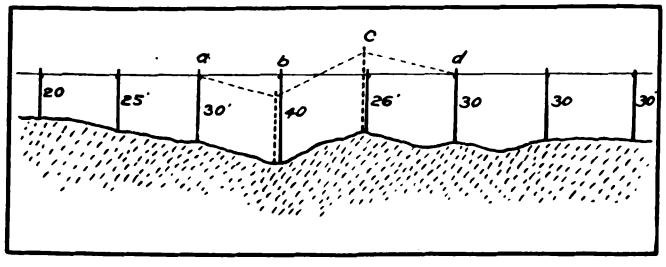

Fig. 3.

right of way, and the wires must be erected at a height that will preclude any possible chance of their being in the way of men on the cars. The laws governing the crossing of railroads by electric companies prescribe certain requirements that must be complied with, and a thorough understanding with the railroad company in question should be had before any work is done. All wires crossing railroads should do so from double-armed poles, or in case no arm is used, two brackets should be placed side by side for each wire. In some States this is compulsory, and it is a good idea to follow in any event.

In case the route passes through swampy ground, or through partially submerged land, note should be made of this in a record, since it may be necessary to use special methods of construction.

From twenty-five to thirty foot poles are desirable when there is no expectation of more than two, or three arms at the most, being used. High poles are more costly, and are more liable to injury from sleet and wind, and for country lines thirty foot poles are very satisfactory. No matter what height may be selected, it

is always advisable to "grade" the line. This means to have no sharp dips or raises in the wires, and can be arranged by keeping note of the topography or surface of the country. In Fig. 3 is illustrated a graded line over uneven ground. Where there is but two or three feet difference in a span it is hardly worth bothering about, but if there is any decided difference, as is the case from *a* to *d* in the diagram, and *b* and *c* where forty and twenty-six foot poles are used, one can readily see that it would destroy the uniformity of the line to a great and

Digitized by Google

injurious extent. Most of the big telephone and telegraph companies grade their lines whenever possible, and one of the telegraph companies goes almost to extremes in this regard. It pays in the end, for there is little liability of the wires pulling a pole out of the ground by contraction, or of getting loose from their tie wires and swinging up in the air above the pole top from the same cause. So a more or less careful grading of the line should be attempted, and note made of the proper height of the poles at the time the route is gone over.

As you go over the route, try, if possible, to find out whose property you are passing, and note how many poles will be placed on this property line. Sometimes a right of way will be refused on one side of the road and readily given by the party opposite. A thorough understanding with the property owners regarding right of way, trimming and guying privileges will make the construction of the line much easier of accomplishment, and while the telephone and telegraph companies always have the "right of eminent domain" in their mind, it sometimes happens that the property owner has a few ideas of his own about the use of the highway. And again, the company may save a lot of unprofitable, roundabout road construction by allowing a right of way across a pasture. It is, in most cases, desirable to keep on the road, as the farm may change hands and the new owner object in after years, and besides, a highway line is more easily maintained; but that is a question for the company to decide.

In going through villages, the necessary formalities must be taken as when you are building through your own town, and all requirements complied with.

A record of the route would look like the diagram we illustrate in Fig. 4.

TESTING BY MEANS OF A VOLTMETER

By Arthur Vaughan Abbott.

Editor's Note.—The Editor of The American Telephone Journal is so constantly the recipient of inquiries with reference to the methods of making electrical measurements with a Voltmeter that he is taking this opportunity of answering inquiries by the wholesale, and simultaneously to suggest, to such of the subscribers to the Journal as are likely to have occasion to desire information upon this subject, that it would be advisable to preserve this number of the Journal, because in the future it will be difficult to supply duplicate copies.

A VOLTMETER is in reality nothing but a galvanometer, and modern forms of this instrument are so designed as to be easily portable, and to be dead beat in their readings. The Voltmeter is an instrument of so universal applicability that no telephone exchange, no matter how small, should be without one; and every wire chief will find it greatly to his advantage to become thoroughly familiar with all of the short cuts in electrical testing, to which the Voltmeter so readily lends itself, because with such familiarity he will be almost instantly ready to take up and locate any cause of trouble as fast as it may arise.

The Voltmeter is supposed to measure electrical pressure, and so it does; but it accomplishes this feat indirectly, because the Voltmeter measures the amount of current that traverses the instrument and not the voltage or electrical pressure which produces it.

The most common form of the portable Voltmeter is shown in the accompanying illustration in Fig. 1. The mechanism of the instrument is exhibited in Fig. 2. This illustration shows the ends of a horseshoe magnet, which forms the foundation of the instrument. Between the poles of the magnet a needle is pivoted, which swings over the scale of the instrument, shown in Fig. 1. This needle swings in jeweled bearings, held in by two brass nuts, the upper one of which appears in the illustration. Around the axis of the needle is placed a coil of fine wire, which is traversed by the current that passes through the Voltmeter. Two spiral springs, which also appear in the illustration, tend to keep the needle at the zero mark. When the current passes through the coil, the mutual reaction of the current and the magnet causes the needle to swing away from the zero point with a force which is directly proportional to the product of the current and the number of turns in the coil. Hence the greater the current the greater will be the deflection of the needle; consequently, in reality, the

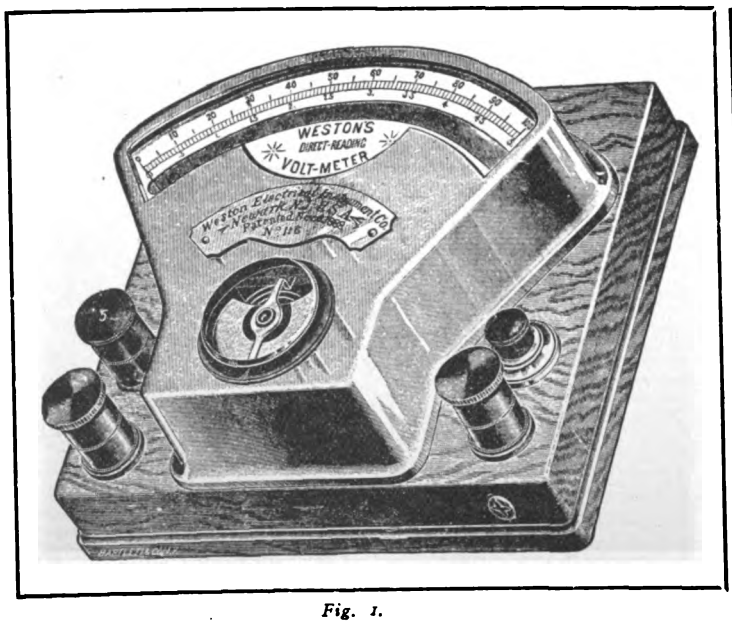

Fig. 1.

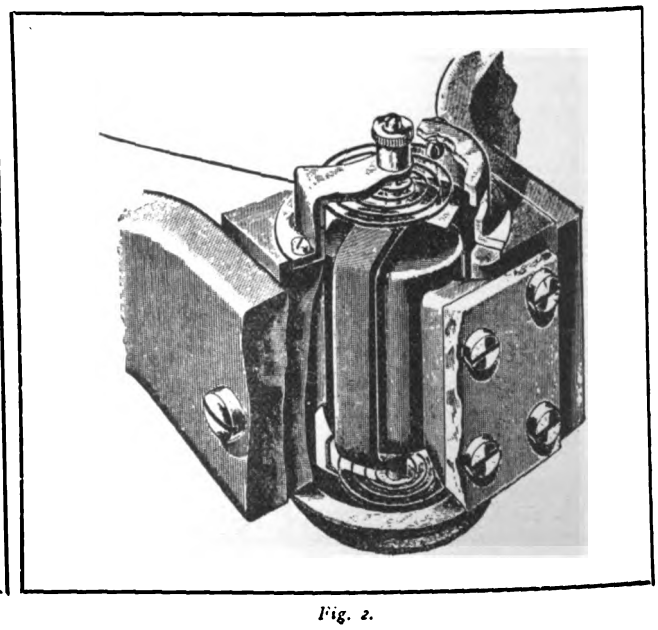

Fig. 2.

Digitized by Google

divisions on the scale of the Voltmeter really represent current strengths in the swinging coil.

If one refers to Ohm's formula $C=\frac{E}{R}$ it is seen that the current is directly proportional to the electromotive force divided by the resistance; hence so long as the resistance remains constant the current will be proportional to the electromotive force which produces it; and thus if a measuring instrument, like a Voltmeter, be wound to a certain definite resistance its scale can be graduated to show electric pressure as proportioned to the current which traverses its coil. This is the principle upon which the Voltmeter operates. The instrument is usually wound with so large a resistance that the quantity of current which traverses the coil is exceedingly small: For example, a Voltmeter to be used on ordinary lighting circuits will have a resistance anywhere from 10,000 to 50,000 ohms; and so, if placed upon a 110-volt circuit, the current in this coil will only be a few thousandths of an ampere. From the foregoing, it is easy to see that the scale upon a Voltmeter will only be correct so long as the resistance of the instrument, or rather so long as the resistance in the entire circuit of the instrument,

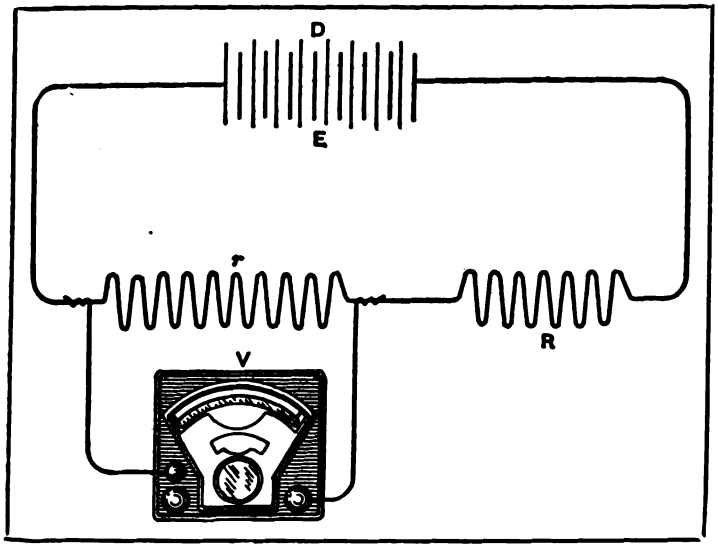

Fig. 3.

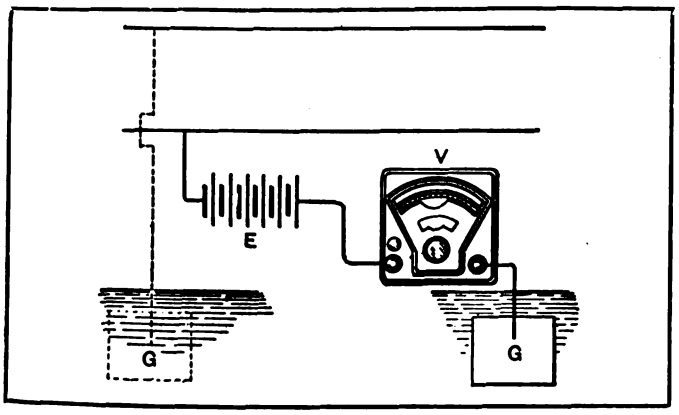

Fig. 5.

and the source of electromotive force which is to be used, remain constant.

To measure the electromotive force, it is common to attach the Voltmeter directly to the poles of the Battery or Generator by means of short pieces of wire. Theoretically the resistance of the leads from the poles of the Battery or Generator to the Voltmeter should be included in the resistance of the Voltmeter; but practically, as these conductors are usually of wire of fair size, their resistance is so small in comparison with the 10,000 ohms or more of the Voltmeter that they cut absolutely no figure. It is easy to see that the range of any Voltmeter can be changed to almost any desired amount by inserting a known resistance in series with the Voltmeter and the electromotive force which is to be used. For example; suppose the Voltmeter to have a resistance of 10,000 ohms and its scale to read 250 divisions. This means that if an electromotive force of 250 volts is applied to the terminals of the voltmeter its needle will be deflected over the entire scale. Now suppose that a resistance of 10,000 ohms be inserted in series with the Voltmeter, the

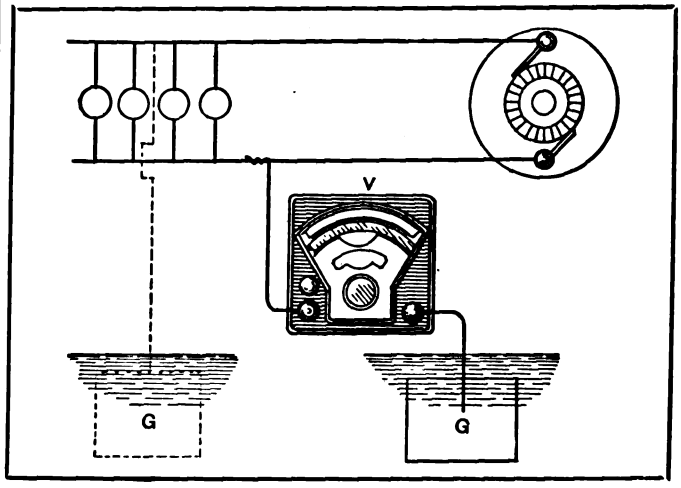

Fig. 4.

Generator giving 250 volts, evidently the total resistance of the circuit has been doubled, and consequently the amount of current which the 250 volts is able to force through the circuit is halved, and the needle will be deflected only 125 divisions instead of 250. This is the principle which underlies all the methods of making resistance measurements by means of a Voltmeter.

In some cases the resistance of the Voltmeter may be unknown, but some other known resistance may be at hand. In such a case the following method is advantageous. Let *E* be

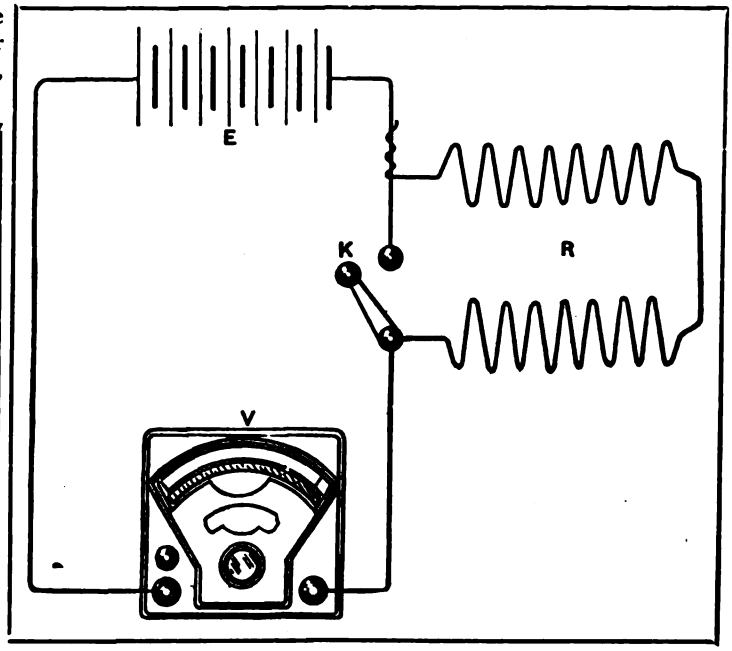

Fig. 6.

the Battery or source of electromotive force which is employed in the test, *V*. the Voltmeter, *r* the known resistance, *R* the unknown resistance which it is desired to measure. Connect the Voltmeter in circuit as shown in Fig. 3 around *r* and take a

Digitized by Google

reading, which may be noted by V. Then connect the Voltmeter in exactly the same way around the unknown resistance R and note the reading, which may be denominated by V^1. In this case the fall of potential or drop around each of the resistances, one known and the other unknown, has been measured, and are represented respectively by V and V^1. Now it is evident that the respective drops are directly proportional to the resistances, and hence may be stated as follows: $V : V^1 : : R : r$, and hence $R = \frac{rV}{V^1}$.

If the resistance of the Voltmeter is known, then the use of the known resistance r becomes unnecessary, as the Voltmeter takes its place, and may be inserted directly in the circuit in series with the unknown resistance R. Then the reading V is that found when the Voltmeter is in circuit alone, and V^1 is the reading in series with the unknown resistance R. Then the preceding proportion holds true, remembering that r is under these circumstances the resistance of the Voltmeter itself. This method is frequently used for the measurement of resistances such as are indicated in Figures 4 and 5.

Figure 4 illustrates the method of measuring the insulation resistance of an electric light line, which may be done while the plant is in full operation. The first thing is to connect the Voltmeter across the leads so as to determine exactly the potential of the Generator, then the Voltmeter is connected as shown in the illustration between one lead and the ground and a second reading taken. Evidently the first reading is the potential of the Generator; and evidently in the second test the circuit includes the resistance of the Voltmeter plus the resistance between the ground and the lead; and hence the preceding proportion may be used to determine the insulation resistance, exactly as has been previously shown.

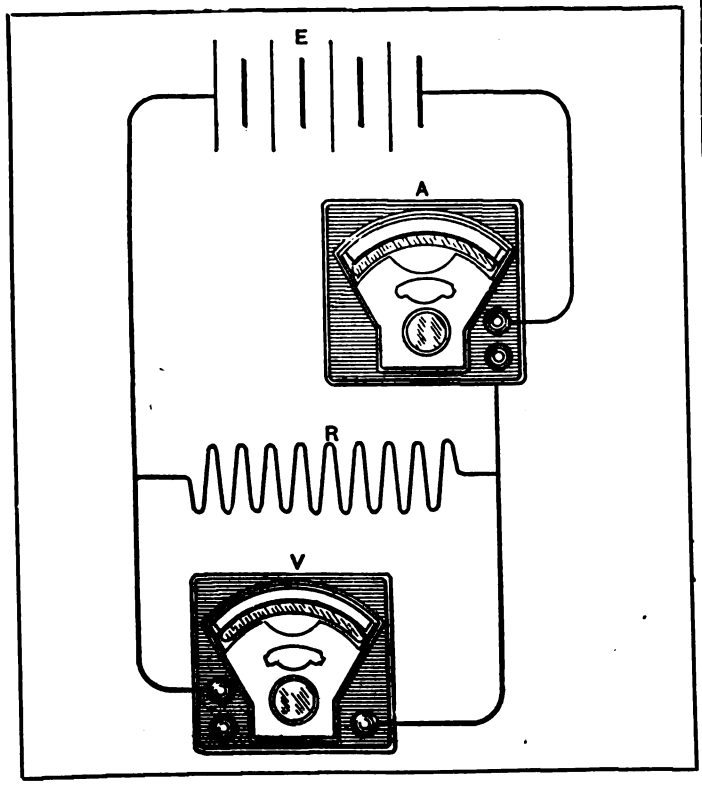

Fig. 7.

Figure 5 shows the method which is very convenient in telephone work, as for example, in measuring the resistance between the cable conductor and the ground. The connections are made as shown in the illustration and two readings made on the Voltmeter, one measuring the potential of the Battery E and the second reading measuring the difference in potential between the line to which the Voltmeter is attached and the ground. Then by setting the three quantities V, V^1 and r in the form of the proportions above given (in which r is the resistance of the Voltmeter) the resistance of the ground is immediately determined.

Another circuit which is sometimes convenient for measuring resistance is shown in Figure 6. In this case, any convenient Battery E is set up in series with the switch K, and the resistance to be measured is placed as shown around K. Now when switch K is closed the resistance R is short circuited and the Voltmeter measures simply the voltage of the Battery E. When the switch K is open R is placed in series with the Voltmeter, and it needs but little consideration to see that this is a similar case to that previously described. Under these circumstances, suppose V to be the Voltmeter reading when switch K is closed and V^1 the Voltmeter reading when switch is open, V^1 of course being less than V, then the resistance R is expressed $R = r\frac{V - V^1}{V^1}$. This formula can be employed advantageously in measuring insulation resistances, as shown in Figures 4 and 5.

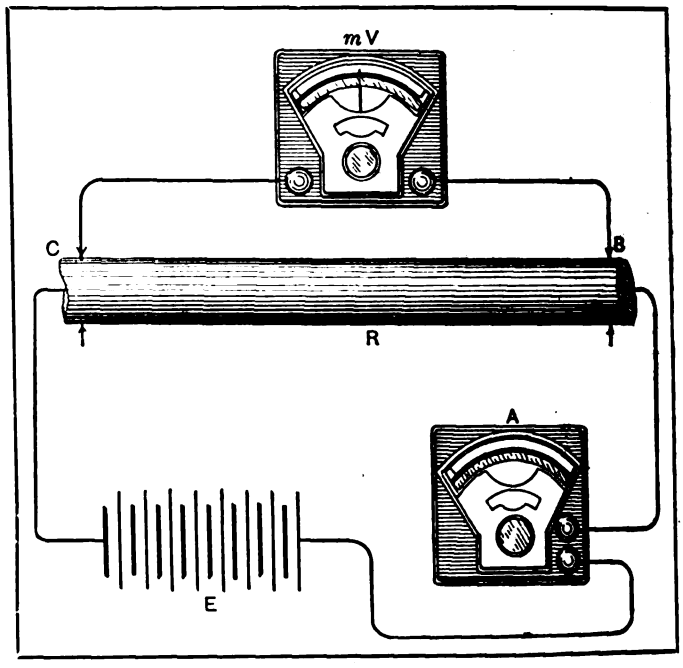

Fig. 8.

It is sometimes very convenient to measure resistances by means of the combination readings of the Voltmeter and Ammeter. For this purpose a convenient circuit is shown in Figure 7. Here E is the source of electricity, A the Ammeter which is wired in series with the Battery E and the resistance R to be measured. The Voltmeter V is placed as shown across the ends of the resistance. Under these circumstances two quantities in Ohm's law are given; that is to say, E gives the fall of potential across the resistance, and C (reading on the Ammeter) is the current that is flowing through the resistance, hence $R = \frac{E}{C}$. This method is exceedingly convenient when it is necessary to measure very small resistances, and when one has a Milli-Voltmeter capable of measuring very small differences of potential. A good plan to be adopted is shown in Figure 8.

The example here given is that showing the resistance of the copper rod R. The source of electricity, E, is attached to one end of the rod, next the Ammeter, A, is placed and lead carried to the other end; then the Milli-Voltmeter is connected between the two points on the rod whose resistance is desired, and the reading of the Ammeter and the Milli-Voltmeter gives two of the quantities in Ohm's law and the resistance may be immediately found as above.

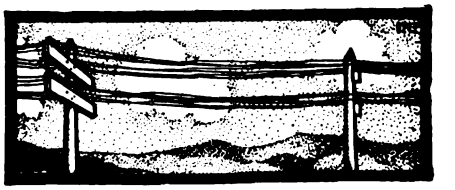
QUERIES

Questions on any subject relating to telephony will be answered on this page.



EXTENSION CIRCUIT.—(456.)

Will you please suggest a circuit for two extension instruments so that all calls can be received at the main instrument but that the extension instruments cannot call the exchange without first notifying the main instrument. G. R.

A circuit which will meet the requirements you outline is illustrated in Fig. 456. The switching key is placed at the main instrument and the signal bell, *a*, is bridged to the main line. By following the circuit through the key it will be seen that the main instrument is normally in circuit. When a call is received for Extension No. 1, the key is so thrown as to move the roller in the direction of *X 1*, opening the circuit of the main instrument and connecting the line to the extension. If for No. 2 Extension, the key is moved in the opposite direction, bridging that instrument on to the main line. Besides this circuit arrangement a call bell circuit should be run to each station to signal them when wanted. Should the key be left in either position besides normal and a call come in, the signal will only be received at the main instrument because the extension instruments have no bells. This circuit is primarily intended for magneto operation.

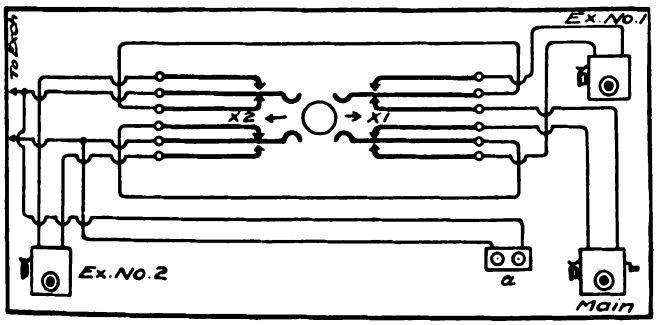


Fig. 456.

BACK BRACE.—(457.)

Can you tell me what a back brace is and what are its uses? N. L. G.

Back braces are put on in addition to the regular ones to offset the strain on the cross arm occasioned by the pull of the lever on curves and corners. Its relation to the regular brace is shown in the drawing, Fig. 457.

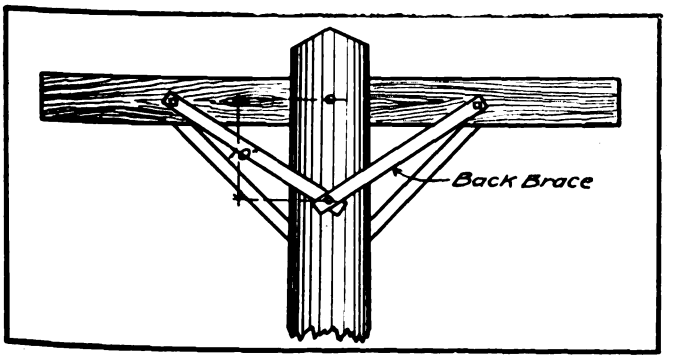

Fig. 457.

CONDENSERS.—(458.)

We have about 400 or more subscribers and common ground return. We use the Stromberg-Carlson S. B. and the condenser, and clearing out drop one bridged one to the other, but in series with the plug and some of the condensers are short circuited. The clearing-out drop being about 350 ohms resistance, which of course will not work when the condenser is short circuited. If I cut the condenser off it increases the cross talk too much. Is there any remedy for it? Can these condensers be fixed or will they have to be replaced with new ones. Please advise. S. McQ.

Whether such repairs as you suggest are or are not practical will depend upon the injury to the condenser. This, of course, it is impossible for us to ascertain here. In many cases it is cheaper to throw the old condensers away and obtain new ones. We believe that the best way for you to do, is to send the damaged condensers to the manufacturers and obtain their advice in the matter. If in any event it is likely that the repairs would require the use of the same originals as used in the manufacture of the condensers, the manufacturers would be in a much better position to make the repairs and do so much more cheaply than anyone else. We believe that the only way to make this circuit work satisfactorily is to see that it is correctly wired with all of the apparatus for which it was originally designed in the perfect condition.

BELL SUBSCRIBER'S CICRCUIT.—(459.)

Will you please illustrate the commony battery line circuit as used by the Bell companies and explain its operation? A. C.

The circuit illustrated in Fig. 459 is the one most commonly used by the Bell companies. As will be seen from the illustration the top side of the line which goes to the top of the jack is normally connected to ground through a spring contact of the cut-off relay, and the line side passes through the line relay to the other spring contact of the cut-off relay to battery. When a subscriber takes his receiver off the hook a shunt is thrown across the line circuit, which causes enough current to flow to operate the line relay. This relay then closes its armature circuit, which permits current to flow from battery through the line lamp to ground, thus illuminating it. When the operator plugs in, battery on the sleeve of her cord flows through the cut-off relay to ground, thereby energizing it and causing its armature to separate the line contacts from battery and ground.

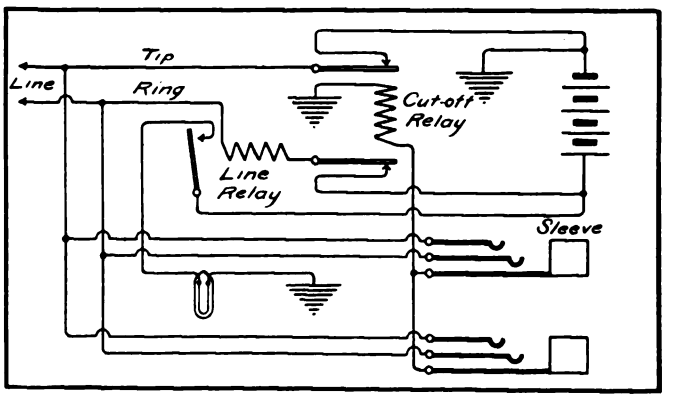

Fig. 458.

The line relay circuit now being opened, the relay is de-energized, allowing its armature to fall back, opening the line signal circuit and thus extinguishing the line lamp.

Battery is supplied to the subscriber's instrument through two windings of a repeating coil over the tip and ring conductors of the cord to the respective springs of the jack.

CELL VOLTAGE.—(460.)

If one battery gives an E. M. F. of 1.5 volts, how can you secure 10 or more volts? Is this possible by taking as many batteries as 10÷1.5 or about 7 batteries? If not, how can it be done? W. H. E.

The only way to secure a greater voltage than is given by the one-cell battery, is the plan which you outlined, namely, by adding successive cells until the required voltage is secured. Inasmuch as there is always some loss in each cell, it is always necessary to add one or two more cells than is shown theoretically by dividing the desired voltage by that of a single cell.

Digitized by Google

A POLE AN APPLIANCE, NOT A PLACE.

A CASE at law was recently decided which embodied some points of interest of far-reaching importance and at the same time determined the legal character of a pole. A lineman in the service of a telephone company was injured by the breaking of a decaped telephone pole which he had climbed in the ordinary course of his duty. The pole which fell was decayed below the ground and was apparently sound above the ground. Before climbing it, the lineman tested its strength by shaking and then climbed it some five or six feet and then shaking it. No weakness being thus discovered, he climbed to the top and while engaged in working with the wires the pole fell. The lineman was one of a gang of men engaged in transposing wires for the company from an old line of poles to a line of new poles on the opposite side of the same country road.

The old line of poles was being abandoned because the poles were old and needed replacement, and this the lineman knew. The gang was under the charge of a foreman, but he was not personally present when the lineman was hurt, gave no direction to the lineman about climbing the pole and made no inspection of that or any of the other poles. The lineman sued the telephone company and the court instructed the jury to return a verdict for the defendant.

It was insisted that the instruction to find for the defendant was erroneous because the defendant owed the duty to provide the plaintiff with a safe place to work. The court held, however, that the pole was more of an appliance than a place. It was next urged that it was the duty of the defendant to inspect and test the poles before requiring the plaintiff to climb them. The court considered that the evidence showed that the defendant had "not assumed the duty of having any inspection of the poles before they were climbed by the lineman." Said the court: "The principle applicable in such cases is that by continuing in the service with the knowledge of the manner in which the business is conducted the servant agrees that the dangers obviously incident to the discharge of his duties when he is able to determine for himself the safety of a particular pole before climbing shall constitute a term to a contract of the employment. It was also urged that plaintiff was an inexperienced lineman and that the company knew this and did not instruct him as to the method of testing the pole before climbing and had not furnished him with the tools adapted to making such tests. The court held that the trial judge erred in taking this question from the jury and reversed the judgment.

IMPORTANCE OF DETAILS IN RURAL CONSTRUCTION.

IN the previous issue of the JOURNAL we started a series of articles upon Rural Line Construction, which we believe will go a long way toward solving a problem which is, quite often, a sticker to the man who has this work in view. To merely put up poles and string wire is a comparatively simple matter, but to do the work in the right way and to lay out a system which, while covering a territory in a thorough manner, yet does so with economy, requires a good knowledge of the principles which underlie telephone engineering. Many a rural line has been put up where only a short while afterwards defects in its construction and operation have begun to crop up, which have necessitated an expenditure to remedy that, added to the original cost, far exceeds the amount which would have been required at the outset had a thorough investigation of the requirements of construction been undertaken. A chain is no stronger than its weakest link, and similarly a telephone system whic hhas one defect is made no better by the excellence of the rest of its construction.

SOME REMARKS ABOUT COUNTRY LINES.

The question of the construction of pole lines is one which, too frequently, meets too little consideration. Poles which are not capable of holding more than a pair of wires are employed, and when it is necessary to add more circuits, poles are overloaded and at the first hard blow or sleet storm they go down. Again, the correct spacing of poles often causes trouble which necessitates a large expenditure for replacement.

Service distribution is another feature of line construction which, if not carefully handled, will frequently bring disrepute upon a system which otherwise has been constructed upon the right principles.

These are but a few illustrations of the desirability of a thorough insight into the construction of a proper rural system, and while the pitfalls for the unwary manager are many, these will serve their purpose in drawing attention to the oft-repeated fact that work is not worth doing unless done well.

TRANSACTIONS OF THE INTERNATIONAL ELECTRICAL CONGRESS.

WE are informed that the transactions of the International Electrical Congress are now being prepared for the press and will contain 153 specially invited papers, together with the discussions thereon at St. Louis, and a report of the proceedings of the Chamber of Delegates. They will form three large octavo volumes, each of which will contain about 900 pages, and a frontispiece engraving, two frontispieces being group photographic views and a third a view of the Electricity Building at the Exposition. The membership roll of the Congress closed on the last day of the meeting, September 17, but anyone desiring to obtain a copy of the Transactions can do so by subscription. Subscriptions will be received until December 1. The subscription price is $10.00, which includes the cost of delivery to the subscriber. As it is not intended to print a reserve stock, and only those for the Congress membership, or on order, are being at present printed, orders should be sent in promptly to the treasurer, Mr. W. D. Weaver, 114 Liberty street, New York City. The volumes will constitute a valuable landmark in the literature of electrical science and engineering.

REGULATION MUST BE GENERAL.

HEARING has been had at St. Paul, Minn., on the application of the Twin City Telephone Company for an injunction restraining the city from interfering with the poles and wires of the company on Hague avenue. The company tried to show that the resolution of the council, ordering the removal of the poles was unreasonable, because sufficient time was not allowed in which to do the work. The company also contended that the resolution was invalid on the ground that it discriminated against the Twin City Company, and took the position that the council had no authority to pass regulations for the telegraph and telephone lines, unless such regulations applied to all lines within the same territory. The city, on the other hand, contended that plenty of time had been given the company to remove these poles, and that a representative of the company was present at the council when the resolution was adopted and made no objection to it. The court took the matter under advisement.

Digitized by Google

The Telephone in the Courts

Conducted by A. H. McMillan.

Readers are invited to submit questions on any point of Telephone Law. They will be answered and explained on this page.

CONVERSION OF WIRES.

The wires of an electric light company were attached to our poles without permission or authority from us. The Board of Electrical Control of the city ordered us to remove all our wires from the poles and we did so, cutting away both our wires and those belonging to the electric lighting company. The electrical lighting company is now suing us for converting their wires and we deny all liability. We gave no orders as to what should be done with the wires and have not got them in our possession. The other company claims that our linemen took them away, but if they did so it was without any orders whatever from us and we have never had anything to do with the wires. Please cite such cases as show we are not liable. A. K. Telephone Company.

WE cannot cite any such authorities as you request, because it seems to us that you are liable for the conversion of the wires, because the act of conversion was so closely and intimately related to and connected with the employment of your linemen that you would be held responsible for their acts. See Electrical Power Company vs. Metropolitan Telephone & Telegraph Company, 148 N. Y. 746, 43 N. E. 986.

REMOVAL OF WIRES.

A few of our wires are strung across a certain street, being attached to poles erected on private land and suspended 30 feet above the street so that they do not interfere in any manner with the use of the street. Can the city council order us to take the wires down, there being no good reason for doing so? Capital Telephone Company.

IT has been held in a case somewhat like yours that the authorities had no right to remove wires which did not interfere with the use of the streets. We could answer your question better if you would make a fuller statement of the facts. See American Un. Telegraph Company vs. Harrison, 31 N. J. Eq. 627, 1 Am. El. Cases, 291.

BREAKING OF POLES.

A heavy wind storm snapped off one of our poles. It fell on a barn and the timbers breaking fell on a horse inside the barn and killed him. The owner is making a claim for damages against our company. Should we settle with him? V. Telephone Company. (Kan.)

THE question of whether you should settle with him is one merely of policy, as there is no liability whatever upon your company. Although a telephone company is bound to exercise reasonable care in the construction and maintenance of its lines, yet it is not an insurer of the absolute safety of its poles. It is not required to erect and maintain poles so strong that no storm can break them, but only to erect and maintain poles of sufficient strength and in such manner as to withstand such violent storms as may reasonably be expected. Ward vs. Atlantic Teleg. Company, 71 N. Y. 81, 1 Am. Elec. Cases, 259; 27 Am. Report 10. Under this state of the law you seem to have a good defence, and unless you can make a very cheap settlement we do not advise one.

LOCATION OF SUBWAYS.

Is the action of the Board of Public Works in locating a subway conclusive, where it appears that the location indicated by it is not the best for all parties? G. N. T.

IT was held in a New York case that the action of the Commissioner of Public Works was not conclusive under a state of facts as follows: The location designated by the commissioner was directly over another subway, and if so constructed it would interfere with access thereto, but there was ample room for a proper construction of the subway on either side of the existing one. The franchise of the earlier company was granted in consideration of the use by the city of one of the ducts in said subway for the city wires. The court held that the action of the commissioner was not conclusive and granted an injunction restraining the construction as prescribed by him. In the absence of a possible interference with the subways of other companies, or a similar situation, the determination of the board of public works would be conclusive. Western Union Teleg. Company vs. Syracuse. 53 N. Y. S. 690.

EMINENT DOMAIN IN PENNSYLVANIA.

THE laws of Pennsylvania provide by clause 1, section 33, of the Act of April 29, 1874, P. L. 92, that the telegraph company should have authority "to construct lines of telegraph along and upon any of the public roads, streets, lands or highways, or across any of the waters within the limits of this State." In a recent case a question arose whether a telephone company in that State possessed the right of eminent domain, it being considered that the telephone company did not possess the right unless it was possessed by the telegraph company. The telephone company contended that the statute quoted should be construed to read as if the qualifying word "public" applies to the words "streets, roads and highways"; but not to the word "lands." The court held that this situation was not reasonable and would not uphold it. It was also contended that a denial of the right of the appellant to enter upon private lands would defeat the grant of the franchise to construct and maintain a telephone line, and that, as the right arose from absolute necessity, the legislature intended to confer it.

The court said upon this point that the telephone lines were generally constructed in the public streets, and when they were built upon public lands it was for the advantage of the company and not because the efficiency of its service would be diminished by keeping on public roads. Said the court: "That the appellant must try to persuade us that we ought, by reading the act with it, discover that it possesses the right to take private property, instead of being able to at once point directly to the words clearly conferring such right, is conclusive that the same does not exist. There must be no effort to prove the existence of such high corporate right, else it is in doubt, and if so, the State has not granted it." The court distinguished the present case by the recent one of Woods vs. Greensboro Gas Company, 204 Penn. 606, 54 Atl., 470, saying: "All that was said was that if the exigencies of the business of the gas company should require the use of a telephone line, the company could obtain authority to construct one by securing in its interest a charter for that purpose, but such line could be constructed and maintained only within the corporate powers and privileges of the telephone company." Penn. Teleph. Company vs. Hoover, 58 Atl. 922.

INJUNCTION AGAINST RAILROAD COMMISSION.

THE attorneys for the Cumberland Telephone and Telegraph Company, at New Orleans, La., have consented to take no action in the matter of the injunction suit recently filed against the Railroad Commission of Louisiana, in which it is sought to restrain the commission from putting into effect orders which seek to protect special contracts claimed by subscribers to the company's service in various parts of the State until the commission's rights in the premises can be thoroughly investigated by the Attorney General. The exchanges to be affected by the proposed new orders are at Donaldsonville, Napoleonville, Thibodaux, Morgan City, Patterson, Whitecastle, Plaquemine and Bayou Sara or St. Francisville. The service which these parties are now enjoying will, therefore, be continued under the present plan until the investigation by the Attorney General shall have been made.

IN THE OPERATING FIELD.

A NEW WESTERN PENNSYLVANIA COMPANY.

THE construction of the new line by the Bruceton and Fairchance Telephone Company will add another link to the extension telephone system of Western Pennsylvania and Virginia. This line will run from Bruceton, in West Virginia, to Fairchance, in Pennsylvania, and will connect with the system of the Tri-State Company.

The new company will operate under an option secured from the Tri-State Telephone Company of Uniontown, which gives it the right to build the line and operate it conjunctively with the latter company, although the right to purchase the line by the Tri-State Telephone Company is reserved, if at any future time it desires to acquire it for the cost of construction. About 2,000 telephones will be added to the field of the local service and a new route will also be afforded to Cumberland.

A number of well-known Uniontown men are interested in the new company. J. H. Walls, of Rockville, W. Va., is the president; George B. Irwin, of Fairchance, vice-president; James Dougherty, F. M. Beeson, Fairchance, and C. C. Frankhouser, W. J. Bowermaster, William M. Wolf and Perry Metheny, of West Virginia, directors.

IMPROVEMENTS TO PLANT OF HOME COMPANY OF SOUTH BEND, IND.

THE South Bend Home Telephone Company recently completed the installation of 56,720 feet of aerial cable to relieve congested lines as a result of the building up of several new additions in the outlying districts this season and the heavy demand for telephone service in various parts of the city. The company also installed 20,000 of underground cable to give service in several down-town districts where there were more subscribers than cable capacity, and also to connect the aerial cable with the exchange.

The company has experienced a wonderful growth during this season and will issue a new directory on January 1 that will list 3,500 subscribers in St. Joseph County.

Elaborate preparations are being made for the annual reception which will be held on Saturday, December 31, owing to the fact that the New Year comes on Sunday. The exchange will be opened for public inspection from 9 in the morning until 9 at night to allow the people of St. Joseph County to make a thorough examination of a modern telephone plant.

HOME COMPANY OF SAN DIEGO NEARLY DOUBLES EXPENDITURE REQUIRED BY FRANCHISE.

FROM a report recently issued by Secretary Godfrey, of the Home Telephone Company of San Diego, California, it is learned that the Home company has spent $52,398.88 as against $30,000 which it guaranteed to spend when granted its franchise. This expenditure is divided as follows: For labor $15,534.84, and material $36,864.04.

According to the franchise $30,000 was to be spent in the second period of the grant which was from the eighth to the twelfth month.

THE ERIE TO BUILD A LONG DISTANCE SYSTEM.

THE Erie Railroad Company will spend about $125,000 in the construction of a long distance telephone line from Cleveland to Jersey City. The poles already in use for the telegraph system will be utilized, thus reducing the cost considerably. At present the Erie has a private telephone system in use between Cleveland and Galion, Ohio, with connections at Leavittsburg, Kent, Akron, and Mansfield. The policy of the large trunk lines in utilizing their right of way for the construction of private telephone systems makes possible a great saving in the cost of construction. At present, besides the Erie railroad, the Lake Shore, New York Central, Delaware Lackawanna and Western, New York, New Haven and Hartford, Pennsylvania, Illinois Central and the Burlington railroads have either long distance systems constructed or else contemplated and in almost all instances these railroads operate local systems at various points along their lines.

THE OTTUMWA TELEPHONE COMPANY REORGANIZED.

THE Ottumwa, Iowa, Telephone Company has recently been reorganized under the title of the Ottumwa Telephone and Electric Company with S. W. Crosby, of Ashtabula, Ohio, president, and H. W. Stecher, of Cleveland, secretary.

Howard Herr will be retained as manager, and will have full charge of the company's interests in this city. Under Mr. Herr's direction the business of the company in this city has continuously grown from a small beginning until now it has nearly 1,400 telephones in the city and 700 in the country immediately surrounding Ottumwa. These, with the connections that can be reached through the exchanges in the smaller towns, Mr. Herr states, gives the subscriber access to about 15,000 telephones in Wapello and adjoining counties. In addition to these arrangements, the line has been entirely rebuilt under Mr. Herr's management. He is an incessant worker and has been the largest factor in bringing the business to its present standing.

In speaking of the new organization, one of the officers said: "The business is now in splendid shape, the details of the transfer have all been finished, and we are now going to still further increase the facilities of the plant and give the best service possible."

NEW PLANT OF PITTSBURGH AND ALLEGHANY TELEPHONE COMPANY.

FOLLOWING out its aggressive policy which has been its best asset since it started, the Pittsburgh and Alleghany Telephone Company has arranged to enlarge its scope of operations by the erection of an exchange building in Knoxville, a suburb of Pittsburg, which will be equal to any similar structure in western Pennsylvania. Last week the company's architects, McClure and Spahr, awarded the contract for the building which will cost at least $20,000. It will stand at the corner of Orchard street and Georgia avenue, a point that commands a magnificent view of nearly the entire city. The excavations have already been started and the building will be finished in about 90 days.

In its design and arrangement the Knoxville exchange building will be very similar to the one recently completed by the P. and A. company in McKeesport. The part to be erected now will be 35 x 75 feet in dimensions. To provide room for future growth the company has wisely bought 40 feet in the rear of this on which the new building can be extended at any time desired. The building will have walls of pressed brick with white terra cotta trimmings and will be strictly fireproof. A well finished basement will extend under the whole structure. The architects have adopted a special design for the building to imitate by appearance the purpose for which it was intended.

The exchange is intended primarily for long distance service,

Digitized by Google

22 positions being provided on the long distance switchboard. In addition to the long distance switchboard space is also allotted for a 3,000 line multiple common battery switchboard for serving the P. and A. patrons in the territory immediately surrounding the office. It is proposed to equip this office in the most modern manner for handling both long distance telephone and telegraph service. All calls from points west of Pittsburgh and those destined to points east of Pittsburgh will be switched through this office over lines which skirt around Pittsburgh. In fact all the long distance service will be kept out of the city lines entirely except when a call is made for a subscriber in the city when the connection will be put up over special long distance trunks. When this exchange is in full operation it will not only greatly relieve the present strain on the P. and A. service due to its marvelously rapid growth but will afford to Pittsburghers and their outside friends by far the best means of long distance communication that they have ever enjoyed.

The interior of the exchange building will surpass any similar building in the city. The offices will be handsomely finished in hard wood and will have tile vestibules. Special provision has been made for the comfort and health of the operators. Dainty lunch rooms, a retiring room and a large reading room will be supplied. The latest and most improved system of heating and ventilation is to be installed and the lighting will be secured by an adequate distribution of skylights and windows.

NEW IOWA CORPORATION.

THE Blakeville Farmers' Mutual Telephone Company, of Dunkerton, Black Hawk County, Iowa, has been incorporated with a capital stock of $5,000. Board of Directors: Albert Holdiman, Ed. Liebert and Herman Katz. Officers: President, C. W. Smith, vice-president, Martin Rinderknecht; secretary, William Rodgers; treasurer, Sidney Weick.

SELECTIVE SYSTEM FOR HOME COMPANY OF OWENSBORO, KY.

THE Home Telephone Company, of Owensboro, Kentucky, will introduce four party selective signaling to its system in the near future. This company has made a number of improvements in the past and under the able management of H. K. Cole has developed a system that will bear comparison with any in the country. Extensive construction of the aerial plant has been under way all the summer.

THE LIFE WORK OF JUDGE THOMAS

JUDGE JAMES M. THOMAS, whose death was announced in THE AMERICAN TELEPHONE JOURNAL last week, was in many respects the most conspicuous figure in the Independent telephone movement. He was an indefatigable worker and almost from the date of his birth in 1858 he was demonstrating to his friends and relatives an ability to achieve results in excess of that quality in the average man. His early life was spent on a farm in Ross County, Ohio, where the elements of his education were received. After a course of study at The Ohio Wesleyean University at Delaware, Ohio, he took up the calling of teaching and held the position as school master for quite some time. Looking round for a better opportunity by which to use his talents, he took up the study of law and shortly afterwards engaged in practice at Chillicothe, Ohio. Honors soon came to the young lawyer, the nomination for probate judge of Ross County being offered to him. To this office he was elected by a large majority, and so well did he carry out the duties of the Court that he was re-elected for a second time. About this time The Home Telephone Company, of Chillicothe, was organized, and Judge Thomas became a stockholder, shortly afterwards being elected president.

The Late Judge Thomas.

His identification with the Independent movement dated from that time, and when the Independent Telephone Association of the United States was organized at Detroit in 1897, Judge Thomas was elected president, which office he held for six successive terms, till 1903. In an address which he made before the National Convention at Chicage on June 24, 1903, he summed up the desires of everyone associated with this enterprise in his final remarks, saying: "What we all want, and what everyone should work to accomplish, is to bring the business up to a commercial level with other public utilities, so that the investor will feel that with greater development comes the more stable investment."

Recent evidence tends to prove the truth of this statement. In another part of this same address, Judge Thomas drew the attention of the Independent operator to the remarkable development made in this particular field. Saying in part:

"Our right having been established, we find as a proof that we were right in our contention, the fact that the investors in this country have placed in use more telephones than are operated by the Bell Telephone Company." That statement was made but a little over a year ago, and yet to-day the insignia of Independent telephony is found in almost every hamlet of this country.

Among the many patent suits which Judge Thomas fought against the Bell, none were of more importance than those relative to the famous Berliner patents which he successfully contested.

Besides holding the office of president of the National Association, Judge Thomas took charge of the United States Telephone Company as general manager in 1899, and later became president of the Telephone, Telegraph and Cable Company of America, which was formed to install an Independent telephone system in New York City. As president and general manager he made a gallant fight to put the company into service, but he did not receive proper support and finally withdrew from the company. The matter of an Independent system was allowed to drop. Shortly afterwards Judge Thomas entered the insurance business in New York City and took up his residence at Irvington-on-the-Hudson, where he was living at the time of his last illness, which ended so unfortunately

If for no other reason, Judge Thomas will always be remembered by his associates and colleagues as a man who believed that he was right, and who in believing fought hard for the purpose in view. To those who knew him personally his loss will be a great blow. He was one of those rare combinations in the business world, a man who could combine lovable traits of character with an earnest endeavor to act squarely with the world at large.

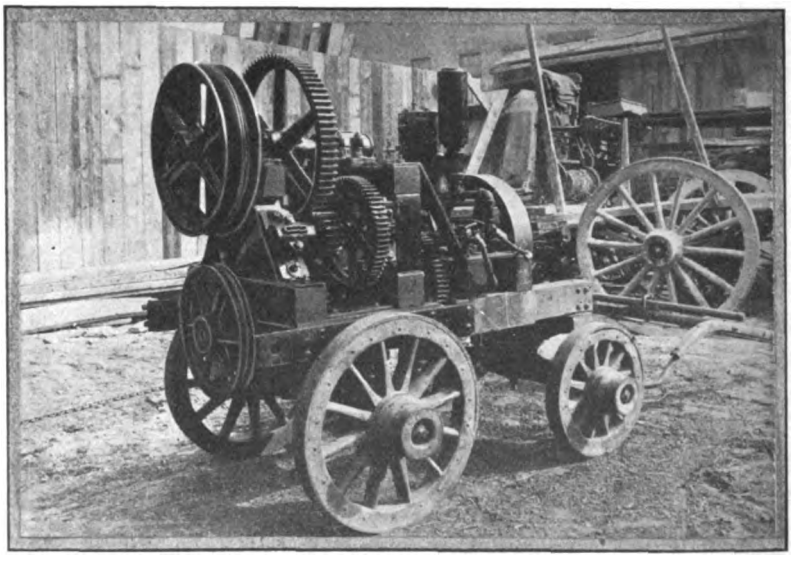
IN THE MANUFACTURING FIELD

"SUCCESS LIES IN THE KNOWLEDGE OF OUR TOOLS"

THE GUNNELL CABLE HAULING ENGINE.

A DEVICE which has attracted widespread attention whenever used is at present being employed by the Lewiston Auburn Telephone Company, at Lewiston, Me., to draw in the underground cables. This machine, a photograph of which is herewith presented, bids fair to revolutionize methods to install cable whether underground or aerial. By its use it is possible to draw in 5,000 feet of cable daily, a task which formerly required the services of nine men for three days to accomplish. It essentially consists of a specially constructed wagon on which is mounted a gasoline engine of seven horse power. By means of friction clutches and gearing this engine drives a winding drum which pulls the cable. Its weight is about two tons, but this is so distributed over the carriage as to not interfere in the least with its mobility.



Gunnell Cable Hauling Engine.

This device is known as the Gunnell cable hauling machine and is employed by the Knickerbocker Construction Company of New York, which has charge of cable work under the supervision of Mr. E. B. Baker, the company's superintendent.

Besides this unique contribution to the field of telephone engineering Mr. Gunnell has devised a shoe which when put in position precludes all possibility of kinking a cable when it is drawn out. Heretofore when cable has been taken out by hand quite frequently the damage by kinking has been such as to render large sections useless for further operation, but by means of this shoe this unnecessary damage has been made impossible so that a cable can be used indefinitely without any danger of its being damaged in installing.

THE FRANKEL DISPLAY FIXTURE COMPANY, 718 Broadway, New York City, was granted a patent on its wire testing clip on November 15, 1904. This clip, which was illustrated and described in this department of a recent issue, is used for making test or temporary connections. It is used extensively by many of the largest telephone companies, and seems destined to soon become universally used.

THE BAIRD MANUFACTURING CO., 4 Michigan street, Chicago, has just received an order for 200 pay-stations from an old customer. This instance only bears out the statement that "once a Baird pay-station user, always a Baird pay-station user." Their catalogue and net price list will be sent to anyone interested in pay-stations and measured service equipment.

THE AMERICAN ELECTRIC TELEPHONE COMPANY, of Chicago, reports among other recent shipments, switchboard equipments sent to the following points: Hinton, W. Va., 25-line switchboard; Haviland, Kans., 100-line switchboard; Rock Valley, Iowa, 200-line switchboard; Grayson, Mo., 50-line switchboard; Auburn, Iowa, 100-line switchboard; Lenox, Iowa, 100-line switchboard.

"AN ANALOGY IN GAS."

UNDER this title THE CONTROLLER COMPANY OF AMERICA, 1061 Monadnock Block, Chicago, Ill., has brought out an interesting booklet, which is somewhat of a novelty in telephone literature. The point is, of course, measured telephone service. The booklet draws a comparison between a gas plant run on an unlimited service basis under which the owner lost money, and his "subscribers" had poor gas, and on a measured service basis under which he made money and his subscribers had good gas and were consequently very happy thereafter.

The story of the gas man as told in the booklet is as follows: He put in a plant large enough to give light to 500 families, with an average of six lights to each family. Charges were based on the assumption that one or two of the six jets would be used at a time. The charge being the same to the consumer whether one or none or six jets were used, needless to say the customers kept them all going full blaze. This reduced the pressure, and complaints of the poor quality of gas were rife.

The gas man then did some reasoning. He discovered he was giving each consumer about three times the amount of gas he had figured on. He recalled that grocers do not ask you to pay one, two or three dollars per so often for the privilege of lugging away all the sugar or coffee or salt you can carry, but weigh it; in other words, measure it. Why not then measure gas? He did. He got more customers and more money from each customer.

THE CONTROLLER COMPANY OF AMERICA, 1061 Monadnock Block, Chicago, entertained the representatives of a number of the World's Fair electrical exhibiting firms on a trolley-car ride, November 10. A fast ride was given them over one of the suburban lines west of St. Louis. Mr. A. H. Stroud was in charge of the private car Mabel, owned by Mr. E. G. Lewis, secretary of the Controller Company.

THE INTERNATIONAL TELEPHONE MANUFACTURING CO., Chicago, it is said, has devised a system which enables it to build its regular self-restoring drop magneto switchboard in such a manner that the system may be used originally as a generator-call local battery plant and changed at any time into a strictly central energy system by simply adding the necessary central office battery or power plant.

Changing from generator-call to central energy does not require discarding any part of the central office apparatus. This enables telephone companies, when rebuilding small generator-

call plants, to first put in the necessary switchboard and later, at any time, install the power plant and make the necessary changes in the telephones and ultimately have a complete central energy system.

A NOVEL WALL BRACKET PIN.

THE wire chief is constantly encountering a problem in the endeavor to run drop wires from the subscriber's premises to the nearest pole line. In the past all sorts of devices have been offered to provide attachments for the insulators so that they may be secured to high walls. Where buildings are of wood, this is not a difficult matter, but in the case of brick and stone it is almost impossible to make a neat and

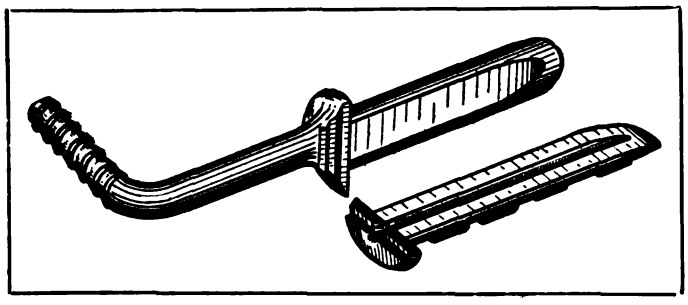

Fig. 2. Parts of Expansion Bracket Pin.

sightly job, and one which is with all sufficiently strong to be permanent.

The Star Expansion Bolt Company, 149 Cedar street, New York, have recently placed a device upon the market which will be greatly appreciated by the wire chief and is illustrated in Figs. 1 and 2. Fig. 1 is a sectional view from which it appears that an l-shaped expansion bolt is provided which is secured by drilling a hole into the masonry of the building wall and inserting therein the shank of the bolt. This is secured in place by driving. The shank is split in two parts which are wedge shaped with reference to each other, as is indicated both in Figs. 1 and 2. The shank carries a collar which bears against the side of the wall, and on the under side of this collar is corrugated. The wedged portion has similar indentations, and consequently when the wedge is driven into the hole in the masonry, it secures the shank firmly in position and the corrugation on the wedge automatically locks it into position by falling into corresponding corrugations in the shank. The insulator may be of any improved type and is secured to the bolt by means of a threaded wooden plug cut so that the interior thread secures the plug upon the bolt while the exterior thread forms an attachment for the insulator. By this means opportunity for expansion is provided so that the insulator is not exposed to the danger of splitting due to changes of temperature.

MR A. B. KRATZ, formerly Cleveland representative of the Kellogg Switchboard & Supply Company, has accepted a position as traveling salesman with the North Electric Company, of Cleveland.

THE SUMTER TELEPHONE MANUFACTURING COMPANY, manufacturers of telephones, switchboards and telephone appliances, with factory and general offices at Sumter, South Carolina, reports that it is enjoying a splendid business. The company is now increasing its capacity about 100 per cent. by the addition of more buildings, machinery, etc.

NEW MANUFACTURING COMPANY INCORPORATED.

PAPERS incorporating the L. M. Ericsson Telephone Manufacturing Co., under the laws of the State of New York have been filed in the office of the County Clerk of Erie County, N. Y.

The capital stock of the company is to be $200,000, divided into 2,000 shares of $100 each. The incorporators and directors for the first three years are Axel Bostroem, of Stockholm, Sweden; Fenton M. Parke, a real estate man of Buffalo, N. Y., and Attorney Carl H. Smith, whose offices are in Ellicott Square, Buffalo. Another man who is active in the organization of the company is Klas Weman, of New York City.

The papers state that the principal offices will be in the town of Tonawanda, Erie County, New York. Tonawanda is a suburb of the city of Buffalo.

According to the Buffalo *News*, the company intends to build a plant for the manufacture of telephone transmitters, receivers and other telephone apparatus under the Ericsson Company's patents. This company's main plant is in Stockholm, Sweden.

FRANK B. COOK, West Lake street, Chicago, has been making several additions to his line, and is now carrying a full line of construction material, on which he is quoting some attractive prices. He is getting up a new catalogue, which will include, among other things, Marlin cable hangers, anchors, messenger

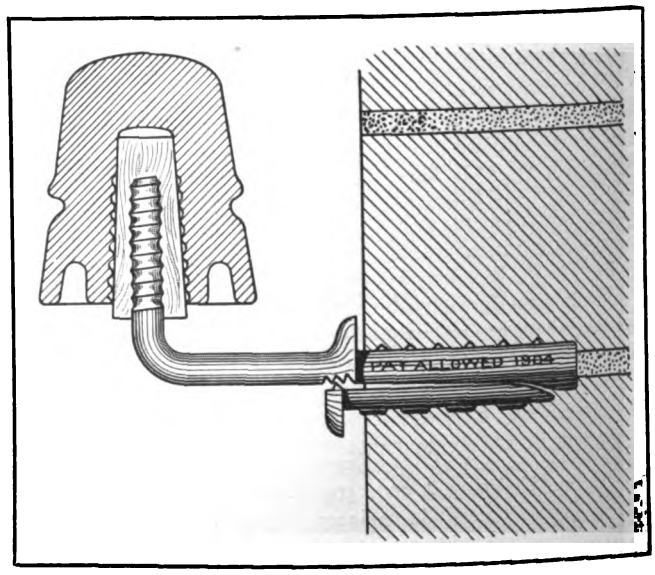

Fig. 1. Section of Expansion Bracket Pin.

hangers, pole steps, insulators, cross arm braces, insulator brackets, brackets, and wooden pins. Cook's name is so well known that it is a guarantee of the quality of the material that will be furnished on orders sent him. A great many companies appreciate the desirability of ordering all their supplies through one house, and will unquestionably take advantage of the opportunity Cook offers.

The sale of Cook's 444 protector still goes merrily on. The principal feature of this protector is the self-soldering, self-restoring,

self-contained heat coil, and it appears to be a very satisfactory feature. The Home Telephone Co., of Los Angeles, Cal., has just put in a great many pairs of the No. 444 protector—1,300 in the East Exchange, 600 in Highland Avenue Exchange, 1,020 in Boyles' Heights Exchange, 600 in Central Avenue Exchange, and 200 in Prospect Park Exchange. The Lake Shore Telephone Co. has put in 100 pairs at their Pentwater (Mich.) Exchange. The Union Telephone Co., of Girard, Pa., have ordered a Cook's Type L board, with 100 pair of No. 444. Other orders recently received are as follows: Home Telephone and Telegraph Co., Riverside, Cal., 1,000 pairs; Lynn Local Telephone Co., Lynn, Ind., 260 pairs; the Illinois Telephone Con. Co., Chicago, a 300 pair addition; Brooklyn Tel. Assn., Brooklyn, Iowa, type L 3-frame, with 70 pairs mounted; People's Telephone Co., Chillicothe, Ill., 400 pairs; Hawkeye Telephone Co., Winterset, Iowa, 360 pairs.

A NEW CABLE HANGER.

THE firm of W. H. Anderson & Sons, Detroit, Michigan, have just placed upon the market a decidedly improved cable messenger hanger, cuts of which are shown below, Fig. 1 representing the hanger as it holds the strand clamped under strain. Fig. 2 shows the hanger before or after clamping, with cap plate turned backward for reception or removal of the messenger strand.

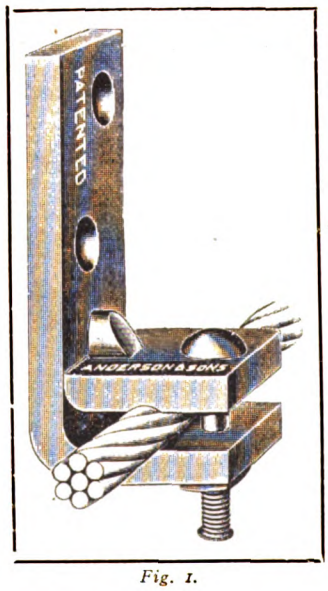

Fig. 1.

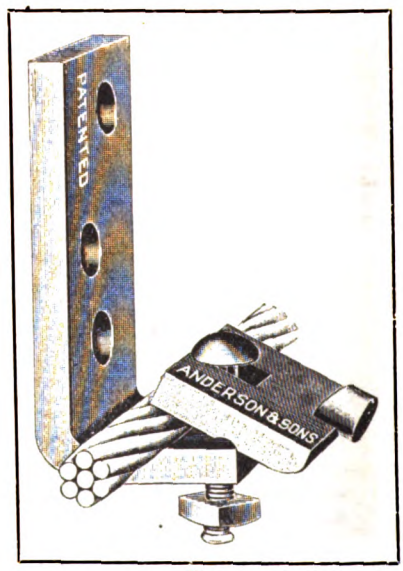

Fig. 2.

The strong points of advantage in this device over the old form of brackets are accessibility, greater tensile strength with less weight of material, lack of the necessity for more than one bolt, and no chance to lost parts, as the nut cannot come off. The cable is nearer to the pole, due to fact that the second bolt is not present.

To unlock the clamp all that is required is to slacken the one nut and slip back the clamp plate until the extension is disengaged from the "L" or frame of the bracket, then the clamp may be thrown into position No. 2 for removal of the strand.

The idea of the whole thing being inseparable must commend it highly to people who are buying construction material of this nature. The matter of messenger hangers is a detail of construction work, but it is the small things that in the aggregate may make or defeat the success of the plant.

You may string a good cable in such a way as to have at the end of a short period a lot of junk. It is analogous to the man building a house on the sand. Don't do it, especially when it costs no more to do it right.

The device shown is the invention of H. D. Stroud, and can be supplied either by W. H. Anderson & Sons, Detroit, Michigan, or the Controller Company of America, 1061 Monadnock Block, Chicago. Samples and prices will gladly be sent to responsible companies or constructors, and the manufacturers will be only too willing to give any further information desired.

THE CONNECTICUT TELEPHONE AND ELECTRIC CO., INC., of Meriden, Conn., report large sales on their low-price toll line switchboards for country lines. These boards are equipped with the highest grade working parts throughout. The hustling efforts of this concern is appreciated by the trade, who desire thoroughly well manufactured articles. The company is now distributing their large No. 8 catalogue describing its many new and up-to-date features, which will be sent upon request.

THE CONTROLLER COMPANY OF AMERICA, at the World's Fair, were honored by a visit from Vice-President-elect Fairbanks and President Francis, of the Louisiana Purchase Exposition, on Tuesday, the 15th.

FRANK B. COOK recently received from two of the large Pacific Coast companies some orders for his type "M" pole-top cable terminals, one of the orders being for 200. Those Pacific States people in the matter of lightning protection are like the baldheaded man parting his hair—he doesn't have to. Lucky dogs!

VOLT-AMMETERS FOR TESTING.

AS important a piece of apparatus as any in an exchange is the voltmeter. By its means almost any trouble can be located and its nature determined. Louis M. Pignolet, 78 Cortlandt street, New York, has on the market an instrument of this character which embodies all the best points in design and yet is moderate in price. To those managers who prefer the use of ammeters in conjunction with voltmeters for testing, and also where storage cells are used, the combined volt and ammeter made by this manufacturer will be found to meet all requirements. Among the many uses to which this instrument can be put might be mentioned tests for insulation on long lines. As every telephone man knows, the high insulation of long-distance circuits is very important for their successful working, especially when their operation depends upon sensitive relays. Louis M. Pignolet has taken especial care to design these instruments for the most practical operations in tests, and will be pleased to communicate with any person interested desiring further information.

THE CONNECTICUT TELEPHONE AND ELECTRIC CO., INC., of Meriden, Conn., are specializing on a very light lineman's test telephone. These sets are appreciated everywhere by the up-to-date exchange man. One style is practically an exact duplicate of the Bell test sets, while the other style has batteries, solid back transmitter, etc. The company has issued a bulletin describing these sets, which will be sent on request. These sets are about 30 per cent. lighter than anything upon the market and are very strongly built.

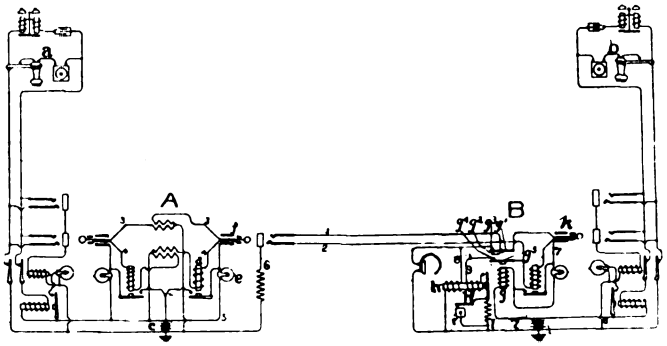
TELEPHONE PATENTS

BUSY SIGNAL FOR TRUNK LINES.

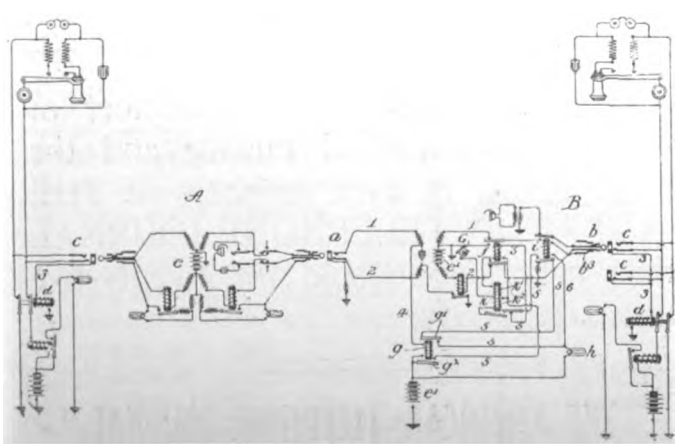
Frank R. McBerty, of Evanston, Ill., patents (No. 772,897) an improved busy signal for trunk lines, and assigns to the Western Electric Company. The object of this patent is to provide a busy signal for trunk lines so that the labor that the operators expend in testing may be avoided. The circuit is shown in the accompanying diagram, the operation of which is as follows: When the A operator receives a call for a distant office, she requests the B operator in the office desired to nominate a trunk line in the usual manner. This the B operator does over an order wire and then proceeds to test the line of the desired subscriber in the ordinary method. If the line is in use, the test current flowing through the tip of the B operator's plug *k* through conductor *8*



excites the test indicating magnet *h* and closes its armature, completing a circuit from the central battery at the *A* office through *2* of the trunk line and wire *9* which maintains the magnetization of the magnet *h* and brings the supervisory relay *d* under the control of the circuit controller *i*. Relay *d* when excited closes a shunt about the supervisory lamp *d*. This lamp was lighted by placing the plug *f* in the terminal jack of the trunk line and remained burning with a constant brilliancy. The circuit controller *i* is a kind of a commutator which is revolved at proper speed and through its action the supervisory lamp *e* is caused to pulsate in brilliancy, thus constituting a visual busy signal to the A operator and indicating to her that the line of the subscriber desired is engaged.

TELEPHONE TRUNK CIRCUIT.

C. A. Crapo, of Denver, Colo., patents (No. 772,871) an improved telephone trunk circuit. The object of this invention is

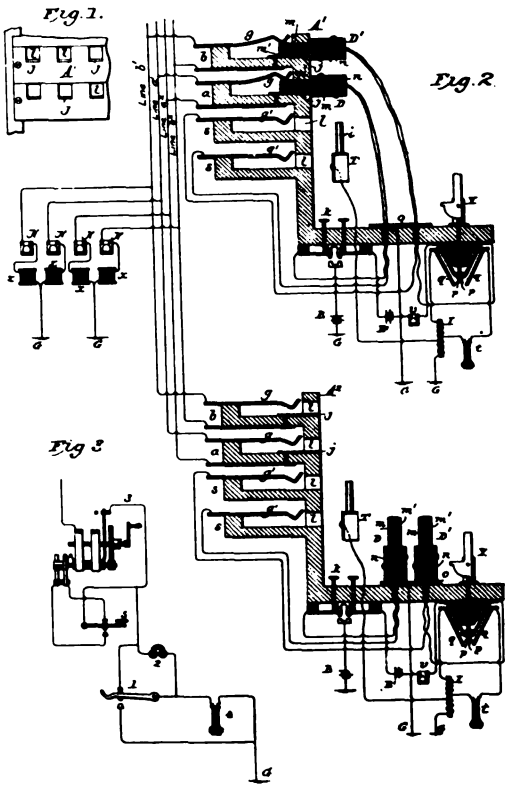


to provide an automatic ringing key to be used upon the trunk line positions upon common battery switchboards so that the subscriber may be called from the A operator's board. The circuit is illustrated in the accompanying diagram. After the A operator has instructed the proper B operator to put up a certain connection, she inserts a plug into the trunk jack designated. Then the relay *g* is excited by current from the battery *e*¹ in branch 4, through line conductor 1 and thence to earth. *g* being excited will draw up its armatures *g' g2* lighting signal lamp *h*. The B operator being thus notified that the A operator has plugged into the right jack, she will insert the trunk *b* into the jack of the desired line, then her work is finished. The insertion of the plug *b* completes local circuit *6 3* and excites relay *i*, completing the shunt circuit *5*, including winding *f* of automatic ringing key. Current from generator *G* then flows through winding *k'* of the disconnected relay *k* to the called line. But this is insufficient to energize the relay until the subscriber answers. When the receiver is removed increased current passes through *k'*, excites relay *k*, through winding of magnet *f* and substituting locking winding *k2*. The ringing key magnet being de-energized will re-establish the talking circuit.

MULTIPLE CIRCUIT.

M. G. Kellogg, Chicago, Ill., patents an improved multiple switchboard, and assigns to the Kellogg Switchboard and Supply Co. This invention relates to the Kellogg divided switchboard and has been in the patent office nearly thirteen years. The accompanying illustration shows the essential features from which it appears from Fig. 2 that the switchboard is divided into two parts A^1 and A^2. The substation is shown in Fig. 3. The ringing

Fig. 1.



generator has a commutator, so that it may supply either positive or negative current, depending upon key 5 being raised or depressed. Thus the subscriber can send whichever form of current to the exchange which he desires. Hence the signals either calling or clearing out may be polarized and thus controlled by the subscriber. The rest of the circuit is so easily traced from the drawing as to render further description unnecessary.

THE WEEK'S MESSAGES

FINANCIAL.

STEWART, GA.—Stewart Telephone Co. has declared a dividend of 20 per cent.

MARSHALL, MICH.—The name of the Marshall Telephone Company has been changed to the Citizens' Telephone Company, and it is reported that its capital stock will be increased to $50,000 from $15,000.

DULUTH, MINN.—The Zenith Telephone Co. will spend one million dollars in enlarging its system.

OXFORD, N. Y.—The Oxford Valley Telephone Co. has increased its capital stock from $1,000 to $5,000.

BROWNSVILLE, OHIO.—The Gratiot & Brownsville Telephone Company has increased its capital stock from $5,000 to $10,000.

FRANCHISES.

HOPEDALE, ILL.—The Farmers Mutual Telephone Company of this city has been granted a franchise in the town of Mackinaw.

JERSEYVILLE, ILL.—The City Council has granted a franchise to the Kinloch Long Distance Telephone Co. of Missouri.

PORT DEPOSIT, MD.—The Town Council has granted a street franchise to the Martland Telephone Co.

ST. PAUL, MINN.—The Twin City Telephone Company has applied for an additional franchise to erect poles and overhead wires in certain streets and alleys in the city.

ELECTIONS.

COIN, IOWA.—At the annual meeting of the Coin-Northboro Telephone Company the following officers were elected: President, J. R. Harris, Northboro; vice-president, Chas. Hart, Coin; secretary and treasurer, P. A. C. Jonasson, Northboro. Directors—J. F. Whitmore, Coin; J. M. Dalby, Northboro, and A. T. Griffin, Hamburg.

HAMMONDSPORT, N. Y.—The Tyrone Telephone Company has elected the following directors: Philander La Fever, Monroe Sutton, Dundee, E. V. Biglow, Chas. Losey, Altay.

ROCHESTER, N. Y.—At a meeting of the Independent Securities Telephone Co. held in Rochester recently, the following officers were elected: President, Thomas W. Finucane; vice-president, Charles H. Poole; treasurer, Frederick W. Zoller; secretary, T. Harvey Ferris. An organization of the new company was perfected and by-laws were adopted.

WESTFORD, PA.—At the annual meeting of the Westford Independent Telephone Company the following officers were elected: President, W. S. McConahey; vice-president, J. E. Coline; secretary, H. D. Bennett; treasurer, G. H. Hurlbert. Directors, T. C. White, Geo. F. Marti and R. Fleming Blair. Manager, Geo. F. Martin.

NEW COMPANY NOTES.

ELKHART, IND.—The Pullman Telephone Company of Elkhart, Indiana, and of Edwardsburg, Michigan, has been incorporated with a capital stock of $10,000.

FLORA, IND.—The Flora Telephone Company has been incorporated with a capital stock of $25,000. Directors: W. E. Callane, H. A. Thomas, W. F. Wagoner and others. They have purchased the system of the Flora & Bringhurst Co-operative Company, and the Miller system.

BLAKEVILLE, IA.—The Blakeville Farmers Mutual Telephone Co. has been incorporated with a capital of $5,000. C. W. Smith is president.

COUNCIL BLUFFS, IA.—The Independent Telephone Co. of Council Bluffs has filed its articles of incorporation, and its application for a franchise.

NORWALK, IA.—The Middle Branch Telephone Co. has been incorporated with a capital stock of $1,200 by W. A. Cotinam and others.

HILL CITY, KAN.—The Mutual Telephone Co. has been incorporated with a capital stock of $11,000.

NEW MARKET, MINN.—The Star Telephone Co. has been incorporated with a capital stock of $10,000.

ARCHER, NEB.—The Archer Independent Telephone Co. has been incorporated with a capital of $50,000 by A. J. Harshberger, J. B. Templin and others.

OSHKOSH, NEB.—The Antelope Valley Independent Telephone Co. has been incorporated with a capital stock of $800 by W. J. McIntosh, J. Pile, W. W. Fought and M. Weatherby.

NEW HAMPTON, N. H.—The Winona Telephone Company has been incorporated with a capital stock of $2,500.

BARTON, N. Y.—The Ross Hill & Barton Independent Telephone Co. has been incorporated with a capital stock of $2,000. Dr. A. J. Terwilliger, president, and F. C. Dailey, secretary.

MARIETTA, OHIO.—The Caldwell Marietta Telephone Company has been incorporated with a capital stock of $25,000 by J. Kaiser, A. L. Gracey, C. B. Barry and others.

GEORGETOWN, S. C.—The Georgetown and Camp Field Telephone Co. has been incorporated by M. W. Pyatt and O. B. Skinner.

LEXINGTON, S. C.—The Citizens' Telephone Co. has been chartered here by J. E. Coughman and A. J. Fox.

MILTON, W. VA.—The Upland Telephone Co. has been chartered here to build a line from Milton to Upland, Glenwood and the Milton oil fields. The officers are: D. L. Irwin, president; J. H. Harshberger, secretary, and S. J. Troop, treasurer.

COMBINATIONS.

CULLMAN, ALA.—The Cullman Telephone Company's stock to the extent of a half interest has been purchased by S. L. Sherrill, of Hartse, from Walter Cable.

WEST FRANKFORT, ILL.—The Stamper Union Telephone Company has purchased the exchange of the Tri-County Telephone Company at Thompsonville.

MORGANTOWN, KY.—The Southern Electrical Construction Company has purchased the local exchange and will entirely reconstruct the system, after which, it is reported, it will turn it over to the Home Telephone Company at Bowling Green.

BALTIMORE, MD.—Articles of merger and consolidation have been filed by the Winchester Telephone Company of Virginia and the Cumberland Valley Telephone Company of Baltimore.

LAKE CRYSTAL, MINN.—Henry Graif has sold his interest in the Blue Earth County Telephone Co. for $6,000.

ARGYLE, WIS.—A. G. Hawley has purchased an interest in the Argyle Telephone Co.

MISCELLANEOUS.

STUTTGART, ARK.—The Stuttgart Telephone Company will be reorganized on January 2d, 1905.

LOS ANGELES, CAL.—The Home Telephone Company is busily engaged in installing new telephones.

RIVERSIDE, CAL.—The building of the Home Telephone Company is being rushed to completion as past as possible.

LEWES, DEL.—The Diamond State Telephone Company has received orders for 27 additional telephones in this city.

INMAN, KAN.—D. F. Penner is securing subscriptions to a farmers' telephone line.

OWENSBORO, KY.—The lines of the Home Telephone Company were damaged by fire due to being crossed with a heavy current.

GRAND RAPIDS, MICH.—The State Traffic Association of Independent Telephone Companies held a meeting in this city recently and discussed methods of business in securing and routing messages.

WOODSTOWN, N. J.—The People's Rural Telephone Company has over one hundred subscribers to start its system with.

COHOES, N. Y.—The Cohoes and Waterford Telephone Company has recently made many additions to its system and now has 750 telephones to install.

BERLIN, ONT.—A rural telephone company is being talked about which will build farmers lines in Waterloo County.

FREDERICKSBURG, VA.—The Toluca and Fredericksburg telephone line, extending from Toluca, in Stafford County, by Stafford Courthouse, Brooke Station and Boscobel to this city, has just been completed and will be in operation in a few days.

PERSONAL.

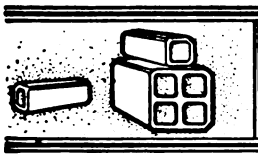
WALTER HARDINGER has been appointed manager of the Ithaca Telephone Company's system at Ithaca.

W. H. LINCOLN has been appointed assistant State superintendent for the Michigan Telephone Company, with headquarters at Grand Rapids.

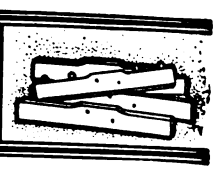
C. L. HOUK has resigned the position as manager of the Local Telephone Company at Norwalk, Ohio.

J. M. FLANAGAN has been appointed manager for the Michigan Telephone Company in Albion.

L. O. WILLIAMS has been appointed manager for the Buffum and Kinloch telephone exchange at Fulton, Mo.



New Construction in the Field



DES MOINES, IA.—The Mutual Telephone Co. is making extensive improvements to its system in this city.

EAST MOLINE, IA.—The Union Electric Telephone Company will connect their system in this town with the lines of the Interstate Telephone Company.

HILLSIDE, IA.—The Union Electric Telephone Company will build a line from this village to Rose Hill.

AUGUSTA, ME.—H. E. Emery is building a private telephone line.

KINGMAN, ME.—Mr. McFarland is constructing a telephone line.

MILLBURY, MASS.—The Millbury telephone exchange was recently increased in size to take care of 100 new subscribers. Extension will be made in the farmers' lines at Sutton and Millbury.

YPSILANTI, MICH.—The Washtenaw Home Telephone Company will construct a system in this city.

ALBERT LEA, MINN.—The 250 new instruments and switchboard ordered by the Albert Lea Telephone Company have arrived and will be installed at once.

ALDEN, MINN.—The Alden Telephone Co. is making another extension to its system.

BELVIEW, MINN.—The Redwood County Rural Telephone Company will establish an exchange in this city and will build an extension from Wabasso to Seaforth and thence to this point.

CAMBRIDGE, MINN.—The Twin City Telephone Company are making extensive additions to their service here.

CLARKFIELD, MINN.—The Clarkfield Telephone Co. has decided to build a new line this winter.

CLIMAX, MINN.—Good progress is being made on the Farmers' Rural telephone line which will be completed as far as Neby this fall.

COTTONWOOD, MINN.—The Home Telephone Co. will build three rural telephone lines.

DELANO, MINN.—The farmers of Lac-Qui-Parle County have organized a telephone company and will build a system and connect with the exchange at Madison.

GREY EAGLE, MINN.—R. H. Sliter will commence the construction of a telephone line, having been granted a franchise.

HARRISON, MINN.—The Harrison Union Telephone Company will extend its line from Peter Berglund's north into Irving.

HUNTLEY, MINN.—The Blue Earth Valley Telephone Co. will build a line to connect this town with Winnebago.

DASSEL, MINN.—The Dassel & Collinwood Telephone Exchange Company have their new exchange in running order. Long distance connections are made with toll lines of the Tri-State Telephone Company and two circuits are used.

LERDAL, MINN.—The Lerdal Telephone Co. is building its system.

LE SUEUR, MINN.—The Farmers' & Merchants' Mutual Telephone Company are building their tenth farmers' line along the old road to Le Sueur Center.

LONG PRAIRIE, MINN.—R. H. Sliter has made arrangements to install a telephone exchange at Grey Eagle.

NORTHFIELD, MINN.—The Northfield Telephone Co. will make numerous extensions in the near future.

PARKER, MINN.—The Steniger Telephone Company was recently incorporated with a capital of $50,000 to build a net work of the rural lines that will center at this place.

RAPIDAN, MINN.—The Citizens' Telephone Co. is building a line to Good Thunder.

RICHVILLE, MINN.—The telephone line has been completed between here and Perham.

SILVER LAKE, MINN.—J. J. Greaves is establishing a local telephone exchange at this place.

WASECA, MINN.—H. Jaehning is considering building a telephone line in this vicinity.

COLUMBUS, MISS.—The Citizens' Long Distance Telephone & Telegraph Company will erect a new building and construct aerial cable lines and other improvements. J. A. Richmond, manager.

ST. LOUIS, MO.—The Kinloch Telephone Company will construct a line from Alton to Jerseyville to connect with the Springfield system.

SEWARD, NEB.—The Seward County Telephone Co. will commence the construction of a local system at once.

TABLE ROCK, NEB.—W. A. Conklin is having an upper story put on his business house to use for a telephone central office.

CHESTER, N. J.—The Chester Local Telephone Company is making preparations to extend its system into suburban territory. A. P. Green is president and G. E. Conover, secretary and treasurer.

HIGH BRIDGE, N. J.—The Farmers' & Merchants' Telephone Company is arranging to extend its line from Annandale to Cokesburg.

BUFFALO, N. Y.—The Frontier Telephone Co. is changing the routes of its underground conduits in Niagara Square.

CANASERAGA, N. Y.—The Livingstone Rural telephone line has been extended to this city.

HAMBURG, N. Y.—The Inter-Ocean Telephone Company is building a line in this village.

HARTWICK, N. Y.—The Hartwick Telephone Co. will extend its system at once.

FINLEY, N. D.—The Union telephone line is to be extended.

GRAND FORKS, N. D.—The new Tri-State Telephone building on Fifth street is fast nearing completion and presents a very substantial building.

MOOREHEAD, N. D.—The Tri-State Telephone Company has constructed a line from Fargo to this place.

CINCINNATI, OHIO.—Sol. P. Kinion has completed a line from this city to Butler, Ky., where it will connect with Independent lines to Louisville.

WAUSEON, OHIO.—The N. W. Ohio Telephone Company is extending its system and will install a switchboard with a capacity of 600 drops.

EUGENE, ORE.—The Eugene-Florence Elmira Telephone Company is constructing a line from this city to the mouth of the Suislaw river, 80 miles distant.

ALLENTOWN, PA.—The Lehigh Telephone Company will install a private branch exchange in the new Allentown Bank.

CONNELLSVILLE, PA.—Work has been commenced on the line of the Tri-State Company, which will connect with Baltimore.

DOYLESTOWN, PA.—The Philadelphia & Easton Traction Company will construct a telephone line along its entire system.

LOVER, PA.—The local telephone company will connect with the Centreville Company in the near future.

WEST CHESTER, PA.—The West Chester St. Railway Company will install a telephone system along its lines and place telephones in all cars.

MARION, S. D.—A telephone line will be built from this town to Freeman.

BRIDGEPORT, W. VA.—The Belmont Telephone Company will run a line to the Lansing and Wheeling Creek mines.

MIDDLEBURY, VT.—The Addison County Telephone Company is extending its system in this city.

KENOSHA, WIS.—The Citizens' Telephone Company will complete its connection between Corliss and Elkhorn, connecting with the Badger State Telephone Company, thus giving Kenosha and Racine long distance connection with Madison, Gainesville, Veloit and Elkhorn.

LARAMIE, WYO.—The J. T. Jones Electrical Company will construct a telephone line from Elk Mountain to Hanna.

BROOKSIDE, W. VA.—The Belmont Telephone Company will complete its telephone cable system to this city within a short while.

MORGANTOWN, W. VA.—The Tri-State Telephone Company has completed its line from Uniontown, Pa., to Pt. Marion, Pa.

SPRING VALLEY, WIS.—During the next year a new rural telephone line will be built by the farmers in this vicinity from this place to Menominee, and another line to Glenwood.

ELLSWORTH, WIS.—The Pierce County Telephone Company will extend its lines.

LA CROSSE, WIS.—The line of the Tri-State Telephone Company has been extended to La Crosse.

THE AMERICAN TELEPHONE JOURNAL

"Work With All Our Strength."

"We are very much pleased with the Journal, and really cannot see how you can continue to give such value for so little money.

"To a company desiring to be up-to-date and to post and educate its employees, THE AMERICAN TELEPHONE JOURNAL is worth ten times the price you charge for it.

"Relative to the man who thought your editorials were narrow and biased: If we claim to be working for some one, then let us work with all our strength. From our standpoint your editorials are correct."

STROMBERG-CARLSON
TELEPHONE RECEIVERS

No. 3.

are made in two styles as illustrated.

We give the purchaser his choice of either type at the same price. We have been building the No. 3 type ever since we began doing business. The many thousands in use are a fitting testimonial to

Stromberg-Carlson Quality.

The No. 6 is just as good as the No. 3. That's all the recommendation it needs. Practically the same adjustment feature is embodied in both receivers, and both

No. 6.

ARE STANDARD.

Consider This Fact. We manufacture receivers by the thousands, every month, and use the most modern labor-saving machinery.

Is It Reasonable

to suppose any manufacturer can sell you a receiver *just as good as ours* at a price from 25 to 50% cheaper?

The argument just as good as a Stromberg-Carlson has helped to sell many receivers. Thousands of users have proven to their entire satisfaction that there are none *just as good.*

We are always glad to mail printed matter.

Ericsson Four Party Line System

For simplicity, satisfactory service and good results, this system takes the lead. The line is perfectly balanced. Each subscriber is called without a chance of disturbing the others. One party can call central without disturbing the others on the line. Absolutely non-interfering. Extremely simple to install, to maintain and to operate. Few changes or additions necessary at the switchboards. Ask for particulars with prices, etc.

We supply party line telephones for common return or metallic circuits, either two or four on a line.

We manufacture a large line of telephones, switchboards and specialties.

Our wall or desk, sets, as illustrated, are growing in popular favor because they are so convenient. Price reasonable

Will you ever again buy cables as cheap as now?

Not unless copper takes a long drop, and none of us look for that. On the present copper market we are selling cables way below what we should. That is plain to any man that figures it. Advances are certain, and coming quick.

Big orders are coming in, and more in sight. Everyone needs cable, mostly big lots. Deliveries will be choked as badly as in 1902 and '03. (Remember them?)

Business is already heavier than most buyers think. Those now under cover are wise, because they will get *their* cables on time, and at present prices.

Profitable contracts for future delivery may be made now if you send us your specifications. Buy enough for all of 1905. It will be good property.

TOLEDO, O. THE F. BISSELL COMPANY

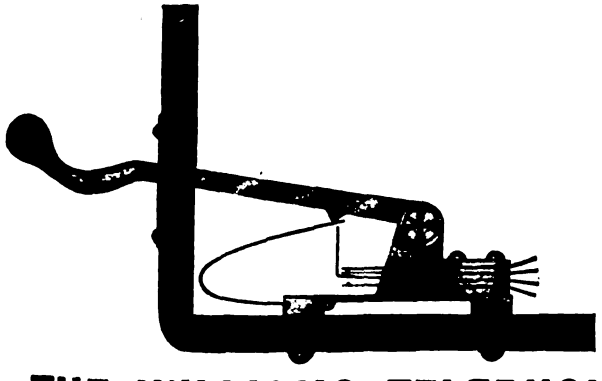
MORGAN & WRIGHT TAPE IS GOOD TAPE

Possesses exceptional adhesive qualities.
Will not dry out.
Unrolls smoothly and easily.
Has uniform insulation.
Is peculiarly free from pinholes.
Has high insulation resistance.
Is capable of withstanding extreme heat much longer than is required by the most severe tests.
Possesses an uncommonly high percentage of insulation composition.

Samples and prices furnished on request.

MORGAN & WRIGHT CHICAGO

NEW YORK SAN FRANCISCO



We call attention to our new style

SWITCH HOOK

which has been pronounced by experts as **ELECTRICALLY PERFECT.** Has four genuine platinum contacts and no pivot connections. Is perfectly **BALANCED** and **ENTIRELY SELF-CONTAINED.** In fact, it is right in line with the entire output of this Company, whose aim it is to keep their apparatus up to the highest standard of excellence.

THE USE OF SURPLUS FACILITIES

By Arthur Vaughan Abbott.

THERE are certain portions of every telephone plant which, from the nature of the business, must always be but partially employed. Such is notably the case with the wire plant. Take the pole line, for example; the expense of providing the poles, erecting and painting them will be approximately the same whether they carry one wire or many. Of course, there may be a slight variation in the cost, depending upon whether large and heavy lines are constructed or whether small or light ones. Similarly in the building of underground lines. The cost of tearing up the pavement and of excavating the trench is very nearly the same whether one duct be installed or a large number.

In order to provide for increases in business from time to time, telephone companies are apt to build wire plant facilities considerably in excess of the immediate needs. In many cases it becomes impracticable to accurately foresee the demands of the future, or the telephonic population may change in such a manner as to cause a surplus of facilities to exist in some districts. In a general way, statistics show that from 20 to 30 per cent. of the cost of the telephone plants is absorbed in such facilities which are not fully employed; and. could some way be devised for utilizing them, the plant would become correspondingly more remunerative. From time to time suggestions have arisen looking towards the employment of these facilities in some other direction. It has been suggested that the telephone company should adopt some sort of fire alarm system, which could be used either in connection with the existing wire plant, or could be made to absorb some of the surplus facilities. The same idea has arisen in connection with electric light plants.

In the past there has been the strongest endeavor to keep electric light and telephone circuits as far apart as was practicable. So long as telephones were operated upon grounded circuits this was absolutely essential, for if the telephone lines and the electric light leads approached each other the telephone lines were rendered so noisy that conversation became impracticable. The rapid extension of electric light facilities, and the increasing use of electricity for other purposes, such as street railways, has now proved that the only salvation for the telephone was to have recourse to completely metallic circuits, and that it was impossible to give satisfactory service over grounded lines. For years the American Bell Company fought for the maintenance of grounded lines, by all of the legal artifices to which it was possible to resort; but in every instance it has been so signally defeated, and the inexpediency of the grounded line has been so clearly demonstrated, that at present it is only employed by small users in remote country districts, where the quality of service is not of marked importance.

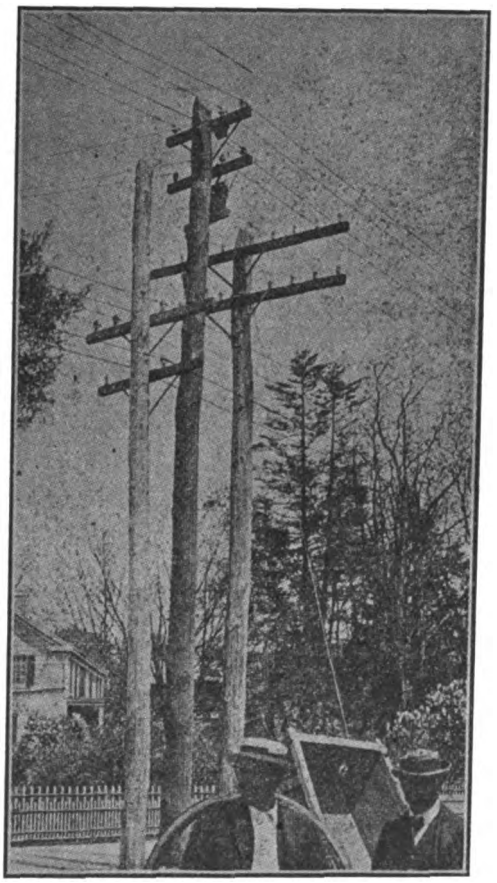

Fig. 1.
Fig. 1. Showing Three Lines of Poles on Same Side of street.

With the banishment of the grounded lines, the chief obstacle to operating electric light and telephone lines in proximity to each other has disappeared. Owing to natural conservatism, there has always been and still exists a great prejudice to allowing the two classes of electric conductors to occupy the same routes; but recently a number of instances have arisen which go to prove conclusively that, with proper precautions, it is perfectly feasible to operate electrical currents of all description heterogeneously mingled along the same routes. Take, for example, the open conduit pole line: Many circumstances often arise that require two or more companies to use the same right of way. It may happen that two electric light companies, two telephone companies or two telegraph companies are all seeking franchises in the same town. Naturally each desires to secure the route which will enable it to distribute its facilities in the best manner and at the least expense. As the streets and highways are only built with two sides, it is a physical impossibility for each of the six hypothecated companies to have one side of the road all to itself, and either some mutual compromise must be reached, or some of the companies must abandon the field, or some must consolidate.

Now, it is obvious that, if some mutually satisfactory, fair agreement be reached, the solution of the right of way problem is accomplished; and there is a further economy secured by so designing the circuits as to enable two or more of the companies to occupy the same poles. There is also now a strong tendency for municipalities to compel all circuits to be strung upon one side of the street, and in many cases ordinances are so drawn as to compel the companies to a mutual occupancy of the same set of poles. Even when franchise restrictions do not exist, it is often difficult to secure the consent of the property owners to the use of both sides of the highway, and frequently much dissatisfaction is expressed when more than one pole is reset.

For example: Figure 1 is an illustration where, owing to franchise restrictions, three companies were compelled to place poles upon the same side of the street, and as there was no hindrance to each one erecting a pole for its own circuits, the disfigurement which resulted is too obvious to need comment. Contrast Figure 1 with the situation shown in Figure 2, which represents the top of a pole occupied jointly by a telephone company and an electric

Digitized by Google

light company, on which the lowest cross arm carried two single phase circuits. For some years this condition existed, and, so far as the telephone subscribers were concerned, no complaints were offered. Consider the economy which would result provided an amicable living arrangement could be arrived at, whereby both companies could mutually occupy the same right of way; or the alternative of the telephone company going into the electric light business, at least so far as might be necessary to build and supply the necessary circuits, that could in many cases be profitably rented to a company desiring to supply electric light and power. There is no doubt that there are good and valid objections to the joint occupancy of poles; but it is a very grave question as to whether the saving and the greater remuneration to be expected upon capital investment does not more than counterbalance all of the objections which have been advanced.

From an operating standpoint it is argued that it is more expensive and difficult to work upon a pole line which carries two sets of wires. This contention is no doubt true, but very few telephone companies use lines carrying but one cross arm; and, so far as the lineman is concerned, it makes no difference whether he is climbing through the wires of one company or another, the difficulty of access to the upper cross arms being precisely the same in either case. Nor is the expense of maintenance increased, for it is no more expensive to repair the upper set of wires when the lower belongs to another company than when it belongs to the one whose wires are in need of attention. It is, however, well to exercise great judgment in designing the arrangement of the circuits. The electric light and power wires are notably larger, stronger and less numerous than the telephone wires, and consequently it is desirable to place these wires on the upper cross arms, and string the telephone wires on the lower ones. Then the greater number of circuits can be reached with much less exposure to the repair man than is the case when he is compelled to crawl through the high tension circuits.

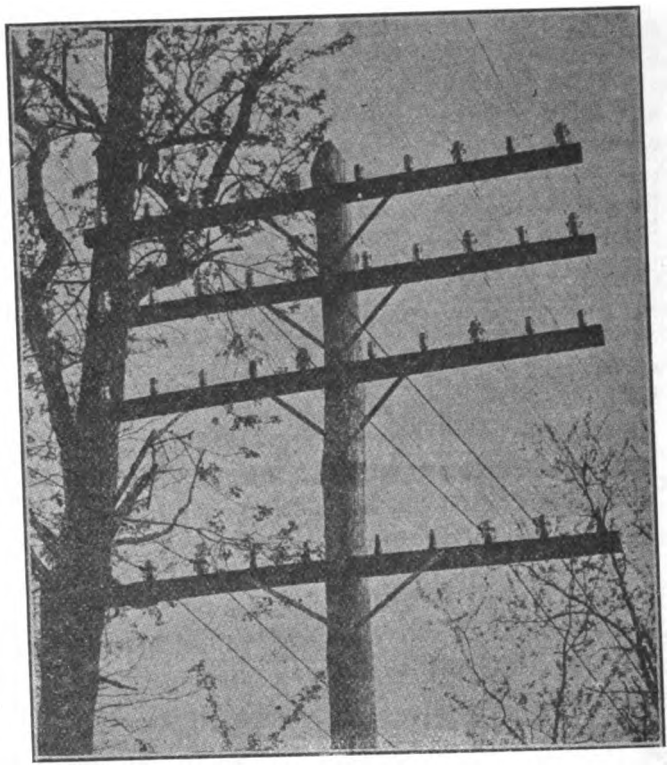

Fig. 2.

Again, the probability of rupture of the wire is much greater in the case of the telephone circuits than with the electric light or power wires, on account of the greater strength of the latter. If a telephone wire ruptures and drops upon a telephone circuit underneath no harm results, whereas if the telephone wires are placed above the high tension circuits, a broken telephone wire may fall upon and cross an electric light line and thus lead a dangerous current to the exchange or the premises of some of the subscribers. So, for these reasons, it is desirable always to place the high tension wires on the upper arms.

In the past the telephone companies have assumed that the presence of high tension wires upon the same pole will interfere by leakage with the low tension circuits, and prevent satisfactory operation. With the improvements in insulation which now exist, no electric circuit should be built with insulation so defective that even a sensitive receiver can be injured by actual leakage. Finally the telephone companies have in the past scored a strong point in advancing as an insuperable objection to the operation of joint pole lines that it was impracticable to obviate such an amount of electrostatic or electromagnetic induction as would impair the operation of two lines. No doubt this is the most serious obstacle, but it is by no means an insuperable one. On the contrary, the instances already cited show that such operation has already been put into practice successfully, and it would be easy to cite hundreds of other cases. Provided the telephone lines are arranged symmetrically with respect to the high potential circuits, and provided the latter are reasonably well balanced and sufficiently transposed, little difficulty will be experienced. Passing now to underground lines, similar conditions exist.

In the conduit line both the telephone circuits and the power wires are enveloped in lead-covered cables, encased with the best insulation, and so arranged that all probability of actual leakage or crosses between the two sets of circuits is reduced to the smallest conceivable minimum. Again, each set of circuits occupies a duct by itself, and is entirely separated from all of its neighbors; and finally both telephone lines and power wires are transposed so frequently as to prevent inductive disturbance. Take, for example, the more recently constructed subways in New York, St. Louis and Chicago. Many instances could be cited where two sets of companies mutually occupy many hundred feet of conduits and are living together in the most amicable manner. Rochester furnishes a pertinent example. Some months ago the Bell Company endeavored to restrain an electric light company from placing its mains in proximity to the telephone lines, but it was shown by photographic evidence that along a number of the principal streets the electric light companies and the Independent telephone company were mutually occuping the same conduits without the slightest interference. To cite further instances is superfluous. And so the shrewd telephone manager immediately goes about and easily finds many methods whereby his surplus facilities may be profitably employed.

At the present time some of the largest Independent companies are considering the addition of electric light and power business to the telephone industry, one instance being the Maryland Telephone Company, of Baltimore. The Keystone Telephone Company, of Philadelphia, recently entered into negotiations for the sale of its subways to an electric lighting company and the parties interested in the Pittsburg & Allegheny Telephone Company have entered the electric lighting field.

THE TELEPHONE IN AUSTRALIA.

AN INTERVIEW WITH JOHN HESKETH.

Electrical Engineer for the State of Queensland, Postmaster-General's Department, Commonwealth of Australia.

ONE of the most interesting visitors to the late International Electrical Congress was Mr. John Hesketh, telephone engineer for the State of Queensland, Postmaster-General's Department, Commonwealth of Australia, who made a tour to the World's Fair with a view to securing ideas upon the most up-to-date construction and operation of telephone systems.

THE AMERICAN TELEPHONE JOURNAL was fortunate in securing an interview with Mr. Hesketh, and we herewith furnish the substance of the matter discussed:

"Any one wishing to join the telephone service must be appointed by the public service commissioners, and is required to pass an examination. The examination of the telephone officers would be of a two-fold nature: first, technical; secondly, the public service, or literary examination, which is the ordinary qualifying examination for the public service. It would depend altogether on the position the officer was to fill, as to what scope the technical examination would cover. In the case of a lineman it is made much simpler than in the case of a technical officer. Female operators are employed wherever possible. Their hours of duty are approximately eight working hours a day, from which may be taken the rest periods in the morning and afternoon, and the luncheon period, but the average time actually worked per fortnight is about eighty-eight hours. They commence at about the age of sixteen, at a salary, speaking from memory, of £26 per annum, and there is a sliding scale by which they advance until they reach the age of twenty-one years, when if they have had three years of service, they must receive £110 a year. The advances are made on a certificate of the officers immediately in charge of the person concerned, as to good behaviour, etc.

"When you ask, what are the rates charged in Australia, it is well to remember that the purchasing value of money is widely different from what it is in the States. Further than that, it is not the function of a government to make any of its departments a profit-making concern. That is to say, if a government provides the best possible service and pays all proper charges, then it has done all that it is reasonably called upon to do, even if it makes no profit. The rates in Australia, therefore, have been designed to this end, and are low when compared with the rates in the States. For instance, the rates in Melbourne and Sidney on direct lines are $45 a year (£9). The population, roughly, is between 400,000 and 500,000. We have very few long distance lines, the longest being about one hundred and sixty-five miles.

"We have not as yet developed party line service. So far our development in that direction has been restricted to extension sets, that is to say, two sets working on one line, the distant station being switched on by the first.

"The Commonwealth of Australia includes New South Wales, Victoria, South Australia, Western Australia and Queensland, on the main land, and Tasmania, a southern island.

"The people of Australia do appreciate telephone communication when they can get it, and there is at the present time a very strong movement in favor of fuller development, particularly of farmer lines.

"We have as yet no common battery exchanges, and the magneto exchanges are many of them out-of-date, therefore, it is because the Postmaster-General wished to know what was the present best modern practice in the States that he sent me over here to investigate such matters, so that on my return I shall be able to advise him what is best to do.

"Speaking generally, we have not nearly so large a development of telephones per 100 population as we might hope to have. In the largest centers we have only a development of between two and one-half and three per cent. So there is plenty of room for expansion.

"A little apparatus is made in Australia, but not very much, not nearly sufficient to meet our requirements. As yet no cable or wire has been manufactured. For details of cost I am compelled to refer you to the published accepted prices in the *Government Gazette*. In this regard, it is just as well to say that we publish all accepted prices, and there is no difficulty in any manufacturer getting to know exactly the price paid for any article.

"Tenders for equipment are called by advertisement in the *Government Gazette*, and in the leading journals of the State capitols,

and also in the case of local requirements in the journals circulating in the area for which the requirements are advertised. We have no system of direct communication with manufacturers.

"The opening for manufacturers depends altogether upon the extent to which the treasurer has funds available for telephone work. This is the only limiting factor. The Postmaster-General controls the posts, telegraphs and telephones of the whole Commonwealth of Australia.

"It seems to me that the most reasonable way for the American manufacturers to get in touch with our market would be for them to obtain copies of the *Government Gazette* to see what lines

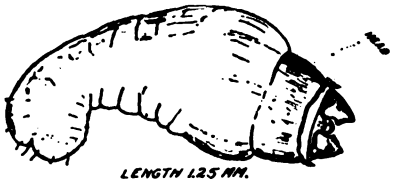

FIG. 3.—ECELONERUS BEETLE.

we are calling tenders for, and submit their standard apparatus designed to most nearly meet our requirements. On the extent of the requirements, as seen by the demands in the *Gazette*, the manufacturers should be able to have a very fair idea as to whether it would pay them to send a representative to Australia as you suggest.

We use just whatever apparatus meets our requirements at the best price. We call tenders for our requirements to fill specifications, and we carefully adjudicate on the tenders received, and give the order altogether on the price, the qualities being equal. In New South Wales, we use Ericsson instruments largely. In South Australia, we have a considerable portion of English manufactured articles, etc. Each place decides its orders on the most favorable tenders.

It is practically impossible to give any details of the scope of our different systems without entering into too long a description of our methods. We have various systems of underground and aerial construction, depending, of course, on the district. In an area so vast as the Commonwealth of Australia, approximating three million square miles in extent, we have such a variety of conditions that the construction and methods must be modified to meet the local requirements of each case. It would be too lengthy a matter to here describe all the different methods, but speaking generally we adopt what may be called standard methods of both underground and aerial construction.

When the inhabitants of any particular town require telephone facilities, they petition the Postmaster, laying their requirements before him. He causes an inquiry to be made as to the probable business resulting from the establishing of a telephone exchange system. On the result of this inquiry action is taken. Speaking generally, the Postmaster-General will establish telephone exchanges in any town where a guaranty is given of twenty-five subscribers."

Besides conducting a very thorough investigation of telephone conditions from every point of view, Mr. Hesketh found time to deliver a paper before the International Electrical Congress which dealt with a new danger to lead-covered cables to which his attention was drawn in 1896, saying in part:

The cables in which the defects were found were of various kinds, the following being the chief types:

(1) Copper conductors, fibrous insulation, anti-induction lead-foil serving, lead-sheathed, and served with tarred tape.

(2) The same, but served with lead-painted tape.

(3) The same as in (1) but with the sheath composed of two layers of lead, a serving of Stockholm tar being placed between them.

(4) Paper-insulated conductors, plain lead-covered.

These cables were all suspended in approximately similar manner from metal hangers on steel bearing-wires; the bearing-wires and sheath of the cables being connected with earth at each pole.

The holes found in the cable sheathing were of various sizes from 1 mm up to 6 mm diameter. They did not uniformly penetrate the lead, in some instances only entering to a depth of 1 or 2

FIG. 6.—ORTHORRHINUS CYLINDRIROSTRIS. FABR.
A lead-gnawing beetle; males and females. Lead-covered conductors, illustrating its gnawing habits. Lead sheathing with perforations probably made by it. *Belus Sp.* (2) Found to gnaw in confinement.

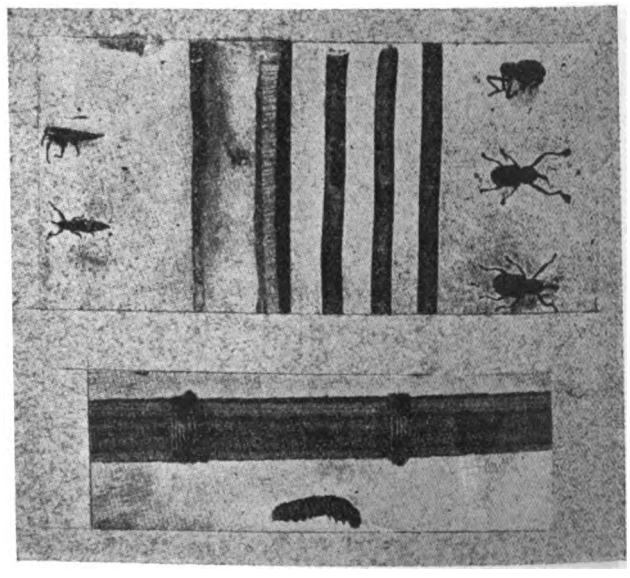

FIG. 7.—XYLEUTES BOISDUVALI. ROTSCH. (ORDER LEPIDOPTERA.)
Partially grown caterpillar, and hole through conjoined lead-covered conductors made by it in effecting exit from telegraph pole.

mm while in others the perforations were complete. There did not appear to be any general damage to the adjoining portions of the cable; that is to say, the damage was confined to well-defined holes either partly or completely piercing the sheathing. A general gnawing of the cable was obtained only when the beetles were in confinement. Fig. 6 shows clearly the difference between the general damage to the small lead-coverd conductors by the beetle in confinement and the clear-cut hole in the larger lead sheath of the cable.

The first direct evidence that insects were the cause of the

Digitized by Google

trouble was found at Townsville in 1903, when the black Jesuit beetle was found in holes in the cable there. Very shortly afterward, very complete investigations carried out by Mr. F. Rosender, telephone officer at Charters Towers, produced the evidence which is embodied herein.

The remedy usually applied when a fault developed in any cable was to have the cable dried out, either naturally or artificially, when the rain ceased, and then close the holes with solder. A remedy for the trouble as a whole has not yet been found.

As the question became one of importance it was referred to the Entomologist for the Queensland Department of Agriculture, Mr. H. Tryon, who wrote a most exhaustive supplementary paper upon it. This supplementary paper being deemed, however, too specially entomological for inclusion as a whole in these transactions, I have extracted fully from it and desire here to acknowledge my indebtedness to Mr. Tryon for his most valuable assistance in so special a subject.

Figs. 1 and 2 show the beetle Ecelonerous (order *Coleoptera*, family *Anthribidæ*) which had been provisionally associated with the beetle larva that undoubtedly traverse lead by gnawing a passage as it proceeds.

Fig. 3 is a drawing made by Mr. H. Tryon from completely dried-up samples of larvæ submitted to him.

The lead-boring habit of this larvæ was brought to light by Mr. F. Rosender, Charters Towers, the original discoverer of the above-mentioned objects and of the grubs or larvæe associated with them. Mr. Rosender not only found these grubs in the perforations while still in process of being made, but he transferred the grubs and their dwellings still attached to the tarred tape, to sections of lead sheathing which he could keep under observation, and he had the good fortune to witness in one instance the act of perforation being pursued by the grub and the method in lead tunneling that it adopted. The specimen so obtained is shown in the center of Fig. 1, where the "mullock-heap" of lead made by the grub can be clearly seen. The specimen from which the photos were taken is also exhibited.

Fig. 4 shows the beetle Xylopertha (order *Coleoptera*, family *Bostychidæ*), of which four dead specimens were, in October, 1903, found in as many perforations met with among numerous others that occurred in a lead-sheathed aerial telephone cable at Townsville. Mr. E. A. Towell, telephone officer at Townsville, collected these specimens and also observed a living specimen emerge from one such hole, proceed along the cable for about a foot and then return on its course. Forty such holes were found in one cable at Townsville.

Fig. 5 shows the beetle Bostrichus Jesuita, Fabr. (order *Coleoptera*, family *Bostrychidæ*) or Jesuit beetle, which is very common in Queensland.

Fig. 6 shows the Elephant beetle (*Orthorrhinus Cylindrirostris* Fabr; order *Coleoptera*, family *Curculionidæ*) and the damage caused by it. When in confinement this beetle has gnawed the lead from covered wires, as shown in the illustration. Mr. Roseneder has also remarked clear-cut holes in the lead sheathing of the telephone cables not corresponding to those made by any other insect that at Charters Towers similarly attacks this substance.

Fig. 7 represents the only instance of the damage to lead-covered wires by this caterpillar (*Xyleutes, Boisduvali*, Rotsch; order *Lepidoptera*, family, *Cassidæ*) that has so far come under notice.

THE CUMBERLAND AGAIN SEEKS A FRANCHISE IN EVANSVILLE

By L. B. Sisson, Special Correspondent.

THE city of Evansville is once more in difficulties with the Cumberland Telephone Company Four months ago the company submitted a proposition to the city council along the following lines: In return for an exclusive franchise for forty-five years the Cumberland Company would pay the city $2,250 a year, or a total of $100,125. No limit was placed upon the maximum rates, which left the city at the mercy of the Cumberland.

Although the mayor was apparently in favor of granting the franchise, public opinion was too strongly formed against it, and the Cumberland withdrew. Now, however, it has resubmitted an almost identical proposition. Just where it hopes to gain its point is not apparent, since the newspapers, notably the Evansville *Courier*, which took up the fight in August, have again pointed out to the people where the danger lies. In a recent article the *Courier* says:

"The Cumberland Company has submitted to the city the same franchise presented three months ago, or in the early part of August. Why the company thinks its chances are better now than then we do not know. The situation has not changed. The same objections prevail now as then, to letting such a franchise or any franchise at the present time. It appears to be the last throw of the dice by the Cumberland Company, hoping to win a franchise on favorable terms before the decision of the United States Court of Appeals is handed down, putting it on the same footing as other companies offering to furnish the local telephone service of the city of Evansville."

This suit above referred to was brought to determine the Cumberland's standing in Evansville. It claims to have a perpetual franchise, which it acquired as one of the assets of the old Evansville Citizens' Company, which it bought out. This the city denies.

Attorney Cranbury for the Cumberland Company stated before the council at a recent meeting that he had strong hopes of winning the case, yet in the same breath he declared that the Cumberland Company would give $100,125 to be sure that they had a forty-five-year franchise. As the franchise that is being fought for is perpetual, how strongly he believes that the Cumberland will win its case against the city is evident without further comment.

In introducing the franchise Attorney Cranbury put up the customary intimidating argument that if the franchise was not accepted the Cumberland Company would abandon Evansville, a city of 70,000 people, the center of its system for 100 miles around, rather than pay one cent more than $2,250 a year for forty-five years. He claimed that if concessions were made in the shape of the fixing of maximum rates that the action would establish a precedent that would jeopardize the Cumberland's business in every large city in which it did business, and claimed that he had had great trouble in getting the directors to agree to even giving so much as $2,250 a year in return for a franchise. If the franchise were granted he again put forth the customary proposal to have the suit against the city dismissed at the cost of the plaintiff. The costs are about $4,500 for each side.

In discussing the franchise the council objected that no maximum rate was fixed, stating that the term of life was too long and the compensation was inadequate. Mayor Covert, who four months ago at the previous presentation of the franchise was an open Cumberland man, was noncommittal as to his position. The mayor, though, is still apparently friendly to the Cumberland interests, for the first broaching of the new proposition was entrusted by the company to him in a star chamber session of the council. That he was unsuccessful in his efforts was proved by the objections raised by a majority of the members of the council in the open meeting. No action was taken by the council on the matter, and it will be discussed again in the next meeting.

PRACTICAL MECHANICS IN TELEPHONY

By Edward Schwartz.

TO exchange managers as well as manufacturers the construction of the various pieces of apparatus is very desirable. A thorough knowledge of the mechanical design is most important, since the successful operation of any part of the apparatus depends entirely upon the design and materials used in its construction. In considering this important detail let us first take, as an example, relays.

The construction of a relay embodies many points of particular value which must be thoroughly understood to ensure its successful operation. The frame, armature and core must be thoroughly annealed. To best secure this result the following method is suggested: All parts should be machined into their final state, that

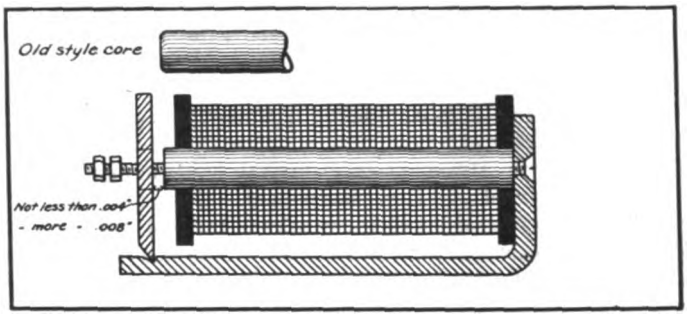

Fig. 1.

is, all holes should be drilled and tapped, all filing, turning and shaping should be done so that there will be no necessity for any machine work being done upon them after they are annealed. Place the parts in an iron pot and thoroughly pack with dust iron chips or borings, being careful that parts do not touch each other. The chips which are used for this purpose must be of cast iron and thoroughly clean. The only way to secure this is to burn them out. If this is not done the smoke and dirt from the heat will cause them to turn off color and the parts will not be annealed.

The pot should then be made perfectly airtight after the cover has been placed in position by means of a layer of clay at all seams. Place the pot in a furnace in such a manner that an equal amount of heat will be available on all sides. This is important, for if the heat is centralized at one point it will be impossible to anneal all the parts the same, consequently some will be harder than others. The best results are obtained from a charcoal fire. This is on account of the uniformity of the heat. Gas should not be used because there is a liability of the blast forcing the gas into the pot, which will discolor the parts, showing that a carbonizing effect has taken place. This causes the iron to become hard, and consequently the effect of softness which was sought will be lost. The pot should be brought to a cherry red and then allowed to cool off in the ashes of the furnace. Do not open the pot until it is thoroughly cooled or the same trouble will be caused as was mentioned in the use of gas.

The question will in all probability arise, Why is it necessary to drill and tap and do all the machine work previous to the annealing process? The answer is this: If the parts are machined after annealing the contact of the tool with the iron surface causes carbonization, which in turn causes hardness. Should the iron possess the slightest degree of hardness it will be possible to magnetize it, and this is the very result that is sought to be offset by the annealing process.

If the iron can be magnetized in any manner it shows that the annealing process has not been thoroughly carried out. A good test is to plunge the part to be tested after it has been subjected to magnetization into a heap of fine iron filings. If any are picked up it is evident the iron is useless for the purpose intended. Another trial method is if the part comes out of the furnace in as finely a polished state as it went in it is thoroughly annealed, but if it shows scale or has turned a dull or blue color it is not. Great care should be taken after the annealing process has been completed that the parts are not roughly handled.

Cores for relays when machined should not have the edge chamfered off which is to be nearest in contact with the armature. The reason for that is this: The area of the pole presented to the armature should be as large as possible. Now, if the edge is rounded off so much iron is lost, and consequently the area presented to the armature is smaller and will not have as great an attractive power as it would were the edges squared. This is illustrated in Fig. 1. In assembling relays the distance between armature and core should not be over eight-thousandths of an inch and not less than four-thousandths of an inch between the core and the armature at the closest point that is illustrated in Fig. 1, where the arrow indicates the points between which this distance should be maintained.

The use of the brass pin to prevent contact between the armature and core should be maintained. An important point in this is that if the armature knocks against the pole piece it is liable to stick or freeze if not properly annealed. Another point is that the pounding of the armature against the core will cause it to harden. Its use is illustrated at *a* in Fig. 2.

The quality of the iron used should be of the lowest-grade carbon obtainable. For this purpose Norway or Swedish iron is the best. A lot of iron is being placed on the market as Norway, or low-grade carbon iron, but they are not as represented.

In many cases cold-rolled steel can be used if thoroughly annealed when the relays do not have to work on high resistance. Insulation for mounting springs should always be of high-grade hard rubber or mica, never fiber, and where terminals lead out of shell the same used. This is especially true where high resistance relays are used, because a slight leakage of current will cause the relay under some conditions to freeze or stick.

Fiber is porous to an extent and will allow moisture to creep into it. It is possible to use fiber in magneto switchboards, such as drops, but in common battery operations it is impossible to

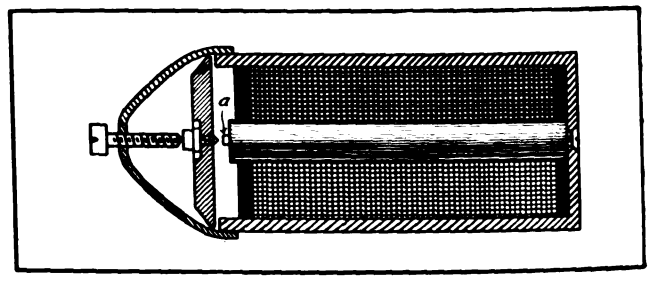

Fig. 2.

secure the high degree of insulation necessary to its successful operation.

Many people place a large amount of faith upon fiber insulation, but it is only necessary to make some tests to demonstrate its impracticability. Fiber can be dipped in hot beeswax and thoroughly boiled out—must be red fiber, not black. Black fiber is dyed, and in consequence is not as good an insulator as natural red color.

Drilling and finishing should be done before loading. It is immaterial whether it is done after mounting or before.

Beeswax is a better insulator than paraffine. Shellac is liable to crack off, besides being hard to handle and to get even results all around.

ELECTION RETURNS ON STREET CARS.

AN innovation in furnishing election returns was given a trial by the electric interurban railway companies entering Indianapolis during the evening following the recent election. The returns were telephoned by the officials of the companies to the conductors of the cars. They in turn read the bulletins to the passengers. As many of the lines are very long the through passengers appreciated the information, as otherwise it might have been hours before they could have learned the results of the election.

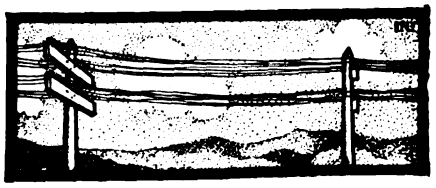
QUERIES

Questions on any subject relating to telephony will be answered on this page.



SELECTIVE SIGNALING.—(461.)

In the so-called Bell selective ringing system wired as shown. How can signal for *A* ring over and ring *X*? *a* and *b* are Jumper wires inside bell box. Is it not necessary to readjust the biasing springs of bells with every change in condition of ground where a rod is used; that is, if ground is frozen or otherwise good or bad? W. Y. O.

In reply to the first part of your query: This trouble may be caused through a high resistance path of ground return to the central office from *A*, the current flowing through the ground to *X* and back over that line. Suppose positive pulsations are sent out over line 2 to ring *A*, then line 1 is connected to ground

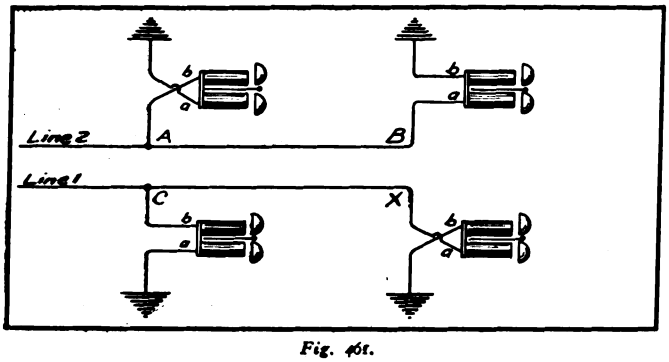


Fig. 461.

through the ringing key, then a condition as above suggested could occur. The same holds true for negative pulsations; in fact, for any combination for ringing any of the bells. The adjustment of the biasing spring is very important and requires a good deal of practice to secure the best results. As to readjustment of springs in cases where ground is liable to vary on account of weather conditions, it may be a slight help, but would require constant attention to give good results. Much the better way would be to sink the ground rod to a point below the ordinary level of frost or preferably to use a copper coil wire buried in coke and set as deep as possible in the ground.

PARTY LINE RINGING.—(462.)

We have a subscribers' line with ten stations on it. As it is we are able to ring fairly well all the parties. We have an opportunity to get six more subscribers further out than the line runs. Do you think we could extend the line to include them and ring the parties O. K., or shall we have to build a new line? Ringers of bells are 1600 ohms. T. & N. T.

Our suggestion would be to build a line which would be long enough to take in about eight of the present subscribers and then extend the old line to take care of the new subscribers and two of the old ones. In this way you may be able to save some wire. By this method you are able to reduce the number of parties on the present line, and in this way the signalling should be improved. On long party lines it is customary to use bells having a resistance of 2,500 ohms.

LOW-RESISTANCE DROPS.—(463.)

We have a number of country lines full metallic No. 12 B. B. iron wire from four to nine miles long and from one to nine telephones on a line. The instruments have 1600 ohm bells and four bar generators all bridging. The lines enter the board through 400 ohm bridging drops. The office has no trouble ringing subscribers and subscribers have no trouble ringing each other on the same line; but all have trouble to throw the drops of their respective lines. Can you suggest a remedy? O. C. S.

In all probability the trouble is caused by the drops being of low resistance and therefore have not enough ampere turns to energize the cores sufficiently to attract the armatures. The drops should have the same resistance as the bells, which in this case is 1,600 ohms, to afford the most efficient operation. It would be as well to look over all the connections to see that none are corroded or loose, as these troubles will cause high resistance, in which case not enough current would flow to sufficiently energize tne magnets.

TESTING WITH MIL-AMMETER.—(464.)

Will you please furnish diagram and information for measuring resistance with mil-ammeter. B. W. H.

It is impossible to measure resistances with mil-ammeter coil alone. A circuit for using mil-ammeter and voltmeter combined will be found in the previous issue of the JOURNAL, to which we refer you.

REWINDING GENERATOR ARMATURE.—(465.)

Will it make my generator stronger to put more wire on the armature, and if so, how shall it be put on? Must I take the wire off on one side and then put on what is necessary and then do the same with the other, or can I connect to the end of the coils now on and add sufficient to both sides? I need a stronger generator for country lines. G. J. R.

The size and amount of wire needed depends entirely upon the style of generator used, whether for series or bridging circuits. In either case it would be preferable to entirely rewind the armature, as it is doubtful whether you could add sufficient wire to help you. If you will let us know the type of generator you contemplate changing we may offer some suggestions.

ARRESTER GROUND.—(466.)

In a telephone plant where a common return is used and the return grounded at eight different placers throughout the system; is it all right to connect the ground wires of the lightning arrester on the telephones to the return wire instead of the ground? J. T. M.

The ground wire of a lightning arrester should be run in the shortest and most direct manner possible. It is obvious therefore that to connect it to the return ground is undesirable. Where it is impossible to secure a ground connection it might be permissible, but only as a last resort.

SIGNAL CIRCUIT.—(467.)

Please illustrate and describe a method of connecting up a drop to a jack so that when a plug is inserted in the jack the drop is disconnected from the line. P. T. S.

A circuit to fit your requirements necessitates the use of a jack which has spring contacts so arranged that the insertion of a plug will separate them. Fig. 467 illustrates such an arrangement. *B* and *C* are the tip and sleeve contacts respectively and

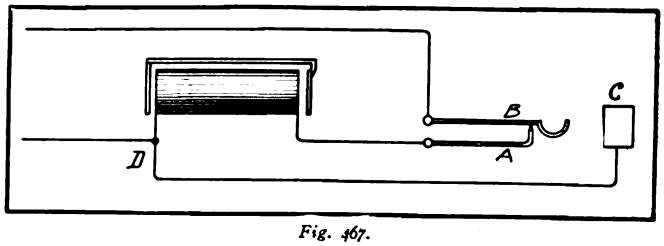

Fig. 467.

correspond to those parts of a plug. The normal circuit of the drop is from the subscriber's instrument to *D* through the drop to *A* and *B* and back over the other line. When a plug is inserted in the jack, the contacts *A* and *B* separate, leaving the drop circuit open; then the line is continued through to the cord circuit.

VOLTMETER TESTING.—(468.)

When a voltmeter is used for testing resistances what advantage is there by reducing the V. M. effective resistances with a shunt? If a voltmeter with a 30 volt range and 10,000 ohm resistance is shunted with a 200 resistance, what formula can be used for testing resistances and line faults? Are voltmeters reliable for capacity tests? B. H.

In the previous issue of the JOURNAL an article was printed which dealt exclusively with testing by means of a voltmeter, and to which we would refer you for reply to this query.

A NEW FIELD FOR THE TELEPHONE.

IT is veraciously reported that a quarter of a century ago, when the telephone was first invented, an astute financier, when invited to participate in the securities of the new discovery, curtly replied that the telephone was unnecessary, as the district messenger boy was amply sufficient for the purpose. Such a prophecy would be now regarded with a smile, for the telephone has permeated almost every department of both business and social intercourse. In the factory it has displaced the speaking tube; in the hotel and department house it has replaced the annunciator and the hall boy, so that one has now to search for a new field of usefulness.

However, a few still remain, notably among them is the possibility of the use of the telephone on shipboard, and particularly on war vessels. Only little consideration is needed to show that here it would find a field of great importance. A large steamship of any description is an exceedingly intricate and complex piece of machinery, and it is at all times operated under circumstances which require the utmost vigilance from its officers, and the most prompt execution of orders to avert impending catastrophe. The tell-tales and telegraphs which are now in use as means of communication between the engine room and the bridge, or other parts of the vessel, are limited in scope, and are only adapted to transmit very restricted messages, and it almost goes without saying that if the captain and all officers were always within instant communication with each other, and that of an instructed nature, many accidents could be averted.

Heretofore telephonic installations upon shipboard have not realized the advantages that would seem to be inherent. Partly this has been due to the fact that it was necessary to use the telephone in a comparatively quiet location, as it was impossible to talk sufficiently loud to overcome the din in the engine room or the roar of battle; and partly because of an ultra conservative fear on the part of the steamship officers that the apparatus was likely to get out of order, and so fail upon perhaps a most momentous occasion.

Certain German manufacturers have recently devoted particular attention to such improvements of telephonic apparatus as will enable it to become serviceable under the most trying circumstances, even those of a naval engagement. In our last issue we described certain of these improvements, whose object is chiefly to provide such telephone circuits as will enable all stations upon the ship to simultaneously connect with all others, and to so install the necessary conductors that they, so far as human foresight can provide, shall be entirely immune from disarrangement, even under the most extreme conditions. Furthermore, particular pains are given to so designing the transmitters and receivers that the parties talking may be supplied with instruments that shall convey messages in a tone sufficiently loud to overcome any amount of extraneous noise, and finally to construct the apparatus in such a manner that it cannot be disarranged or thrown out of commission even by the concussion caused by the explosion of the largest guns.

To what extent these results have been achieved by the apparatus described can only be determined by experience; but we believe that sufficient progress has been made so that even a naval commander is amply warranted in installing a telephone system upon a war vessel, and, at least, applying it to the practical test of experience of a sham battle. If the apparatus now available, together with such refinements as the experience of the future will inevitably suggest, shall prove to be what is expected, a facility of almost incalculable value is placed in the hands of steamship officers, of which they will do well to avail themselves.

RECENT DEVELOPMENT IN MARINE INSTRUMENTS.

A LESSON OUT OF THE STORM.

THE recent storm which swept across the Atlantic seaboard demonstrated in a most graphic way the necessity of suitable line construction. Up through the New England States the damage done to telephone poles and wires was something enormous. In one locality along the line of the Canadian Pacific Railway, near Vanceborough, Me., for twenty miles every telephone and telegraph pole was blown down by the furious gale, and for almost a week telephonic and telegraphic communication was cut off from a large number of towns and villages throughout the State of Maine. A rough estimate of the damage done would not be far short of $250,000, but this does not account for the loss of business to the telephone and telegraph companies.

The development of the telephone and telegraph has been such that a single pair of conductors is being used to convey anywhere from two to six different messages simultaneously. The working of composite lines composed of telephone and telegraph circuits brings in a large revenue to telephone companies, and when for any reason this service is cut off a great financial loss occurs.

From this it is clear that the attention paid to an aerial plant should be greater than to any other part of the system, since it alone has to withstand the elements.

The very best solution of the problems incident to the operation and maintenance of line plants is the substitution of underground distribution for aerial wherever possible. The construction of underground systems may involve a greater outlay at the start, and in the case of long distance circuits it is generally impracticable, yet the time is not far distant when the aerial wire line will be a thing of the past. In European countries underground long-distance circuits are quite common. In England the general post-office department has built a subway from London to Manchester, and is extending it to towns much farther north. While the present consideration of underground construction for long-distance lines is out of the question it is well to consider the engineering details which should be carried out in the construction of an aerial plant that is going to withstand the ravages of wind, rain, snow and time. Many long-distance companies employ for this branch of the business poles which are stout enough to carry 100 wires and which are not more than 25 feet high. By using such solid construction the maintenance upon a long-distance trunk line is very materially reduced, and although the initial cost of such heavy poles may be considerably greater than the ordinary pole of a similar height, yet it would be more economical in long lines to use timber which is of a substantial character. When a pole line goes down it does so nearly always at an inopportune moment, when it is difficult to be replaced, and then the delay in closing the circuits causes a great financial loss. It is therefore evident that the operation of long-distance lines necessitates a thorough understanding of the principles which underly outside construction.

The Telephone in the Courts

Conducted by A. H. McMillan.

Readers are invited to submit questions on any point of Telephone Law. They will be answered and

RENTAL OF TELEPHONES.

Several years ago we made an agreement with one of our subscribers by which we were to lease him the use of a telephone wire for two years at a rent payable quarterly. After the expiration of the two years we continued the arrangement by mutual consent. Telephone rates afterwards went up and on the last day of the quarter we gave him a notice ending the agreement at once, stating our intention to discontinue the wire and remove the apparatus and at the same time demanded the rent up to the 1st of the month. This was really a mistake on our part because the quarter ended on the 30th of the month. He paid the rent. Now he brings an injunction to restrain us from taking out the apparatus. Has he a good case?

N. C. T.

WE think his chance of getting an injunction is good. The relation between a telephone company and its subscriber is that of landlord and tenant. His tenancy was from year to year, and the acceptance by you of the rent beyond the end of the year, even though it was only a day's rent, renewed the agreement for another year. It also nullified the effect of the notice that you had previously given. See Joyce on Electric Law, Section 1027.

DELIVERY OF TELEPHONE MESSAGES.

Is a telephone company under the same duty to deliver messages intrusted to it as a telegraph company is? Please explain the law on this point.

G. L.

TELEPHONE companies, so far as this feature of their business is concerned, are held to the same degree of diligence and are as strictly liable for the non-performance of their duty as are telegraph companies. If the telephone message shows its importance and is to be sent to an addressee in care of another, the company is negligent if, without inquiry when sendee is there, it delivers it to a person of the same surname but a different Christian name from the one in whose care the message is in, when the latter is shown by the directory to be within two blocks of the company's office, and in said directory said name is connected with that of the sendee. Martin vs. Sunset Telephone Company, 18 Wash. 260, 51 Pac. 376. This case shows that it is the duty of a telephone company as well as of a telegraph company to make due inquiry and to exercise reasonable diligence at least to find the person to whom the message is intended to be delivered and to deliver it to him.

EXCLUSIVE RIGHT TO SUBWAYS.

IT is a general rule that the individual cannot maintain a suit in equity to restrain the violation of a statute enacted for the protection of the public, unless he shows that he has been or will be injured in person or property by the violation of the statute. It must be shown that the plaintiff has sustained or will sustain special damage. This rule is applicable to private corporations as well as to individuals.

This was the ruling in an action by an electrical subway company to enjoin a cable railroad company from maintaining electrical wires in the cable conduit, or using any electric conductors not placed in plaintiff's subways. The right of constructing subways in certain streets and of leasing space therein to persons operating electric conductors had been granted to the Electric Company. The court would not permit the Subway Company to enpoin the maintenance of electrical wires in such street, not placed in its subways in violation of the laws relative to electric conductors, unless complainant company had an exclusive right to have all electrical conductors placed in its subways either by contract or by statute.

Taking up this question the court held that the contract between the city and the Subway Company by which the city granted to the company the right to construct subways in the streets, and providing that the contract should be without prejudice to the rights of the city to enter into other similar contracts and that nothing in the contract should be construed as granting any exclusive right. The application for an injunction was therefore overruled.

Empire City Subway Company vs. Broadway and S. A. R. Company, 33 N. Y. S. 1055.

AGENT'S ADMISSION BINDING ON PRINCIPAL.

A SUIT for damages was brought by one Prince against the Texas and Pacific Telephone Company, the damages being alleged to have been sustained by him as a result of a fall occasioned by becoming entangled in a wire negligently left in the streets of the town by the defendant. Plaintiff alleged that while endeavoring to break the force of the fall he cut his thumb, causing the joint to become stiff, which thereby permanently incapacitated him from pursuing his occupation as a saddle and harness maker. Defendant demurred generally and specially, and in addition to the general denial pleaded contributory negligence. A trial resulted in a verdict in favor of the plaintiff for $450. The company alleged that the wire was left in the streets by some other person and that the negligence, if any existed, was attributable to the town and not to the telephone company. Evidence showed, however, that the local manager of the telephone company, when shown the wire, said: "That is our wire." The court overruled the assignment of error based upon this defense.

Another matter of defense was that agent of the telephone company had no authority to bind the company by his admission. It was shown in evidence, however, that he presented and collected bills of account for the company, had charge of the construction and repair of its lines and acted for the company in regard to the action. The court held that the evidence showed that the local manager was clothed with such power and authority as rendered his declaration admissible.

Another assignment of error was the failure of the court to submit to the jury the question of plaintiff's contributory negligence. The court concluded that there was no evidence of contributory negligence and said in relation thereto: "It certainly cannot be affirmed that the party is guilty of negligence because of the mere failure to closely scrutinize the sidewalks of the city." Texas Pacific Telephone Company vs. Prince, 82 S. W. 327.

BACK-TAX PETITION.

SUIT against the American Bell Telephone Company for back taxes for five years, aggregating $250,000, has been filed by the State Revenue Agent at Lexington, Ky.

The petition alleges that the company, which was created under the laws of the State of Massachusetts, was the owner at the time stated in the petition of certain personal property in Fayette county, Kentucky, consisting of telephone lines, leases and telephone instruments valued at $50,000. It further alleges that this amount was omitted from assessment and taxation for the years of 1899, 1900, 1901, 102 and 1903, and is still omitted, the defendant company failing and refusing to list this property for taxation for all of these years. The plaintiff prays that the property be now assessed as above mentioned and 20 per cent. still be added as penalty. The taxes claimed to be due on the property will amount to $3,000.

IN THE OPERATING FIELD.

INDEPENDENT ASSOCIATION OF WISCONSIN TO HOLD MEETING.

THE next annual convention of the Independent Telephone Association of Wisconsin will be held at Milwaukee on January 25 and 26. Owing to the importance of telephone matters that are to be considered the meeting has been called a month earlier than usual. The headquarters and meetings will be at the Pfister Hotel. A large attendance is expected.

BELL RATES IN SALT LAKE CITY TOO HIGH.

THE Business Men's Association of Salt Lake City, Utah, is making an effort to relieve its members and the public generally from the extortionately high rates charged by the Bell Company. At a recent meeting a commitee was appointed to investigate the matter and to conduct a campaign with a view to securing all the business and professional men of the city to join the association. The committee is as follows:

H. S. Joseph, chairman; A. Hudson, E. E. Rich, J. L. Franken, Samuel Weitz, Jacob Moritz, C. N. Strevell, C. J. Crabtree, G. F. Strickley, Eber W. Hall, Maurice J. Friedman, N. B. Roberts, A. H. Kelly, B. F. Redman, N. B. Campbell, Dr. S. C. Baldwin and Steven H. Love.

Several sub-committee were also appointed to secure information as to rates charged in other cities, and to confer with the management of the telephone company.

CONSOLIDATION OF ILLINOIS COMPANIES.

THE Farm and City Telephone Company, of Clinton, Ill., has sold its entire system to the National Telephone and Electric Company. This company has also bought the Farmers' Interstate Telephone System, and has consolidated these two companies into one with B. F. Wasson, of Clinton, Ill., president, and S. H. Martin, of Waynesville, Ill., secretary and treasurer. The new company has increased the capital stock from $50,000 to $100,000, all of which has been sold. It will put up 16,000 feet of cable this fall and add such other improvements as the business necessitates.

Besides reaching into six counties of the corn belt in Illinois it has connections with all the towns in the center of the State, and will soon be connected with the Interstate Telephone Company, which will give it toll service to all the principal cities from Chicago to St. Louis and Kansas City.

PORT ARTHUR'S RESERVE INCREASING.

THE municipal telephone plant established several years ago by the town of Port Arthur, Ont., for public service in opposition to the Bell plant at that point, is continually adding to its number of subscribers, and also rapidly increasing its reserve or surplus fund, as will be seen from their statement, as appeared in the November issue of the *Railway and Shipping World*, of Toronto, Can., which is as follows: "The Port Arthur, Ont., municipal telephone plant earned as gross income for the half year ended June 30, $2,679; the operating expenses were $1,783, and the interest charges $450, leaving a surplus of $446. For the year 1903 the total earnings were $3,774 and the surplus $419. The amount of telephone debentures outstanding is $21,000, bearing 5 per cent. interest, and of this amount $12,000 is being offered by the Dominion Securities Corporation, Toronto, at 101 and accrued interest. The telephone plant was installed November, 1902, and in September there were 433 subscribers, of whom 199 were for business telephones and 284 for instruments in private houses. The system is a central energy one, and free connection is given to Fort William. The rates are $12 for instruments in private houses and $24 for business places."

The municipality, when starting the service, aimed to arrange their charge of rentals so as to place the plant upon a purely maintenance basis. This was done that subscribers to the service would not be required to contribute into the city treasury to the benefit of the tax-payers of the town who were not subscribers, and vice versa. From the statement given above, showing that the surplus for the first six months of the present year was more than for the entire year previous, it can be seen that their estimates have included sufficient for almost any emergency. The outside construction of the system having most of its heavy leads in lead-covered cables and the equipment being of the "International" central energy lamp signal type, which is considered one of the most economical and durable telephone systems to maintain, the plants will require the setting aside of a very small percentage for depreciation.

LONG DISTANCE CONNECTION FOR HULL COMPANY OF NEODESHA, KAS.

THE Hull Telephone Company, of Neodesha, Kansas, has recently completed a long distance traffic agreement with the Western Independent Telephone Company, which is building a line from Kansas City to Cherryvale. When this line is completed the subscribers to the Hull system will have long distance connections with Iowa, Indiana, Illinois, Ohio and Missouri.

In Kansas City the connection will be made with the Home Telephone Co., which has 22,000 telephones in that city against 15,000 on the Bell system.

FIRST INDEPENDENT LINE INTO CINCINNATI.

THE first message over an Independent telephone line from Cincinnati was sent to Kentucky recently over the Kineon lines, after much litigation. The message was sent from the Kineon offices on East Fourth street to Butler, Ky., to which point the Independent telephone lines of Kentucky extend, connecting with the Homer Telephone Company, of Louisville. The circuit extends from the Kineon offices over the Central Bridge to Newport, thence over housetops to Covington, where the Merchants' Police franchise is owned by Kineon, thence southward through Visalia, Kenton, Morning View and the Government rifle range. About the time the messages were being sent to and from Cincinnati and Kentucky towns, Judge Shaw issued an order directing the Merchants' Police and District Telegraph Company to show cause why it should not be punished for contempt.

THE UNION COMPANY, OF DAVENPORT, TO CONNECT WITH THE INTERSTATE.

WITHIN a few weeks the Union Electric Telephone Company will connect at East Moline, Iowa, with the Interstate Company, which is at present constructing a line from Galesburg to Sterling. A spur will be run from the main line to East Moline, which will give the Interstate Company connection with the tri-cities.

At present a large gang of workmen is being employed between Watertown and Rose Hill, and the poles are all in place between Hillsdale and these points. It is understood that an-

Digitized by Google

other gang is working east from Hillsdale and that the line will soon be completed to Sterling.

The Interstate Company has exchanges at Peoria, Galesburg and in nearly every town and city in the eastern part of the State.

The Union Electric Company, of Davenport, Iowa, has made an agreement with the Crescent Telephone Company of the east end of the county for free exchange. Under this arrangement nearly 500 subscribers in the eastern end of this county and from various points in Whiteside county will have free exchange with the telephone patrons in the tri-cities.

OPEN WIRELESS IN DES MOINES.

THE reconstruction of the Des Moines Mutual Telephone Company's plant on the "open wireless," or all cable, system is progressing rapidly under the engineering supervision of Mr. C. H. Judson. The company has erected a fine fireproof building for its central office and a new lamp-signal central-energy switchboard of 9,600 lines capacity is about completed. All open wires throughout the entire city will be taken down and everything put into cable, something like 300,000 feet of cable being used, 5,000 pairs of conductors entering the two exchanges.

The Mutual Telephone Company is in a very prosperous condition and is taking between 200 and 300 contracts a month for installation as soon as the new plant is completed. Its toll-line connections are exceptionally good, some thirty-six circuits at present radiating in all directions and connecting with the entire Independent system of the State.

LONG-DISTANCE LINE FROM PITTSBURG TO WHEELING.

THE long-distance line of the Pittsburg and Allegheny Telephone Co. to Wheeling is being pushed rapidly to completion. This line will connect the P. & A. system with Independent telephones in Northern Pennsylvania, reaching the principal towns, such as Warren, Girard, and Titusville. This line, together with the one to Johnstown, will give unequaled telephone facilities to the towns of Western Pennsylvania, and will besides afford long distance connection to towns and cities in Ohio, Indiana, Virgina and Maryland.

HOME COMPANY OF KANSAS CITY BUYS STOCK OF WESTERN INDEPENDENT COMPANY.

THE Kansas City Home Telephone Company has purchased all of the stock of the Western Independent Telephone Company, which company owned the long-distance toll line out of Kansas City. The deal has been consummated and the Kansas City Home Telephone Company now owns and controls both the Home plant and the long-distance lines. The Kansas City Home Telephone Company now has over 10,000 telephones in operation, and is increasing its list rapidly. At the present time the traffic reports show an average of 2,000 calls each twenty-four hours.

ELYRIA PLANT MAKES IMPROVEMENT.

THE Elyria (Ohio) Telephone Company is just completing its new multiple tap cable system of distribution. Several thousand feet of underground cable has been drawn into the conduits, and over one hundred thousand feet of aerial cable put up, and a new common battery multiple switchboard has been installed. It is the company's intention to furnish all classes of service, such as individual and party lines and measured service, so as to meet all requirements of office and residence subscribers. The engineering and management of the plant is under the supervision of Leroy W. Stanton, consulting and constructing engineer, of Cleveland and Chicago. Mr. Stanton is rebuilding a number of plants and taking up the management and engineering details with a view to increasing the earning capacities of the plants. By reorganization of the various departments and a thorough system of records and reports he is able to keep a close check upon the cost of maintenance and operation.

The system of accounting is one devised by F. H. McPherson, chartered accountant under the Canadian Government, and McSanton. By means of a thorough analysis of the various systems of bookkeeping employed by Independent companies they have been enabled to devise a system which gives clear and concise information. By an agreement with the owners of the plants the managers under Mr. Stanton's supervision are promoted as they prove themselves capable. In this way the owners as well as the men are benefited and opportunities are opened for advancement to the industrious men.

TELEPHONE PROGRESS IN NEW ZEALAND.

A RECENT report of the Postmaster General and Electric Telegraph Commissioner for New Zealand gives some interesting facts of the development of the telephone systems in the two islands.

In 1903 there were 1,161 kilometers of telephone lines, consisting of 15,823 kilometers of wire. There were 2,103 subscribers in Wellington; 1,707 in Auckland; 1,579 in Dunedin; 1,479 in Christchurch; 425 in Wanganui; 334 in Napier; 335 in Invercargill; and 320 in New Plymouth. Besides these there are about four other places with between 200 and 300 subscribers; nine with 100-200; six with 50-100; and 53 with less than 50.

Up to April 1, 1904, £1,053,692 was paid by the Treasury for the construction of telegraph and telephone lines, and the following figures show the progress of the telephone service:

	Capital expenditure.	Receipts.	Expenses.	Balance.
1900.....	£162,333	43,303	46,567	— 3,264
1901.....	£176,349	49,117	45,348	+ 3,769
1902.....	£193,512	55,542	50,772	+ 4,770
1903.....	£213,966	62,151	56,277	+ 5,874
1904.....	£241,903	72,028	60,948	+ 10,080

The construction of rural lines for farming communities is being investigated, and in all probability the development in the next year will greatly exceed any that has occurred in the past.

THE COHOES AND WATERFORD HOME COMPANY PROSPEROUS.

THE Cohoes and Waterford Home Telephone Company is meeting with much success in those cities, a large number of subscribers having been added to the list within the past several months. The line plant consists of underground conduit and cable work in the business district, large enough to accommodate a capacity of 3,600 telephones with an overhead construction for aerial cables.

The company has now under contract in Cohoes and Waterford 750 telephones and is placing new instruments daily.

LETTER FROM C. H. JUDSON.

THE following letter has been received from Mr. C. H. Judson in reference to a notice given him in a recent issue:

"*Editor of* THE AMERICAN TELEPHONE JOURNAL:

"In your issue of November 19th, under the head, "The Mutual Telephone Company of Des Moines Extends Its System," you state that I have been secured to look after the business of the company. Permit me to make the correction that I have been secured simply to construct the plant for the company in the capacity of engineer. You also state that the immense subscription list of the Kansas City Home Company was the result of my efforts; in justice to the gentlemen who have made the Kansas City Home Company what it is, permit me to say that during my brief connection with this company my work was altogether in other lines and had nothing whatever to do with the subscription list."

"C. H. JUDSON."

It appears we were in error and take this opportunity of correcting the statement.

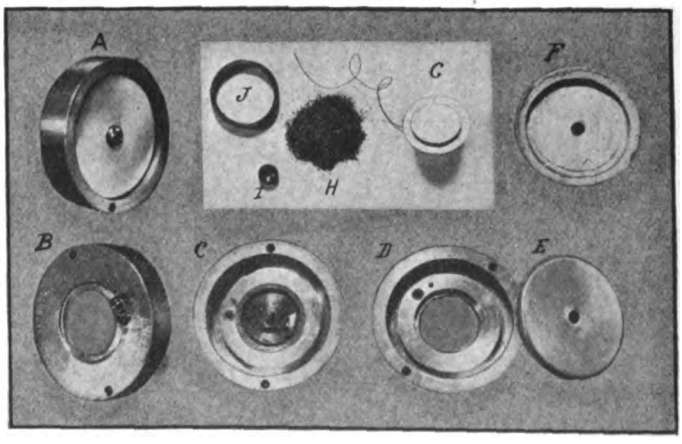
IN THE MANUFACTURING FIELD

"SUCCESS LIES IN THE KNOWLEDGE OF OUR TOOLS"

A NOVEL TRANSMITTER.

THE Fahnestock Transmitter Company is placing upon the market a form of transmitter which, in its mechanical details and execution, is a decided novelty. The original White Transmitter received the appellation of "The Solid-Back," in contradistinction to the old Blake instrument; because in the White one carbon electrode was mounted immovably against a metal bar or bridge, and, compared to the spring contact of the Blake transmitter the White was indeed a "solid-back." But the present design of the Fahnestock instrument might be called the "solid-back of solid-backs," for the instrument is built in the form of an exceedingly heavy and rigid metallic capsule. The entire transmitter is shown at *A*, and seemingly consists of a round disc of metal about two inches in diameter and half an inch thick. Upon one side appears an aluminum diaphragm secured to a central stud. The back of the metal block contains, as is shown at *B* in our illustration, a screw, to which one electrode may be attached, while the other is secured to any part of the case. If the aluminum diaphragm be removed, as is shown at *C*, the interior mechanism is displayed. The metal block is composed of a peculiar composition, which can be cast closely to shape, needing but the slightest amount of trimming in the lathe. As is indicated at *C*, the face of the disc is surfaced and a deep groove cut near the circumference, while the center is hollowed for the purpose of receiving the granular carbon. At the bottom of the central cavity a carbon electrode is placed, as is shown at *D*, then the granular carbon *H* is introduced, and the front electrode, which is clamped to a mica diaphragm by means of a brass nut, is placed on top of the carbon, retaining it in position. The mica diaphragm is then secured in place by the brass ring *J*, which is pressed into the cavity and holds the diaphragm firmly against a ledge, which may be seen at *D*. Then the aluminum diaphragm, shown at *E* and *F* is placed over the central stud, which projects through the mica diaphragm and is held in place by the brass nut *I*. From this construction it will be seen that the instrument is exceedingly substantial, the rear electrode being solidly supported by the entire disc that forms the frame work.



Parts of Fahnestock Transmitter.

The aluminum diaphragm is made as light and as thin as possible, and as, as will be seen, is supported simply upon the stud through its center; consequently this diaphragm is freerer to move than is possible with any form of transmitter holding the diaphragm by its circumference, with the electrode attached to its center. Thus it seems probable that the vibration of this diaphragm will more faithfully represent sound waves than would be the case in other types. As the metallic capsule contains the entire transmitter mechanism, it is a complete unit of itself and may be placed in any kind of a case, with or without a mouthpiece, according to the fancy of the user; in fact, all that is necessary is to attach one of the capsules to a bit of flexible cord, and one may talk over any telephone line.

THE FARR TELEPHONE AND CONSTRUCTION SUPPLY COMPANY, of 118 and 120 W. Jackson boulevard, Chicago, has issued a new catalogue, No. 17, which it aptly styles a book of information. Descriptions are given of almost every article necessary in the construction and operation of a system, each article being illustrated and thoroughly described. All types of instruments for magneto systems are portrayed and indexed in such a manner as to be readily located for future reference. Among the pieces of apparatus described are magnetos, ringers, transmitters, receivers, switchboards for exchanges, toll and rural lines, backboards, drops, annunciators, hooks, induction coils, plugs, jacks, terminals for aerial lines, fuses, arresters, switches and batteries. In construction material almost every appliance known to the trade is listed, including tools, insulators, pins, brackets, bolts, braces, cables, wire, etc. Diagrams are furnished for connecting up various types of instruments, also for making transpositions and connecting up repeating coils. The volume concludes with some tables and some instructions for building farmers' lines.

THE MONARCH TELEPHONE MANUFACTURING COMPANY, 14 So. Clinton street, Chicago, reports a large and increasing business in its compact type telephones. This class of instrument embodies many admirable features in construction and is so designed as to allow all of the parts being readily removed without disturbing the permanent wiring. Especial attention has been given to the design of bells and generators for heavily loaded lines, and the transmitters and receivers are the equal of any on the market. To those managers looking for the right article at the right price the company recommends this instrument. Descriptive matter and prices will be mailed upon request. This company also manufactures a number of different telephone and construction specialties which it would be well for exchange managers and operators to know about. It has unequalled facilities for filling orders promptly and will be pleased to hear from all parties interested.

THE BAIRD MANUFACTURING CO., 4 Michigan street, Chicago, Ill., have received a letter from a customer in the Southwest which illustrates in very strong language one of the features of Baird pay stations. They lost the combination card of the pay station, and therefore, of course, could not open it. Part of the letter is herewith reprinted:

"We are unable to open this pay station, and have had no advice from your company as to the combination. If this is the manner in which you wish to impress upon your customers that your machines are burglar proof, I will say that we are convinced. Nothing short of an axe, sledge hammer or the combination to the lock would, in our judgment, open it. Therefore please send us the full directions at once to open it up."

Telephone companies who are using pay stations which they do not feel will withstand the wiles of a thief might take the above as a good hint as to where they can get pay stations which will turn over to them all the money that is put into them. The company will furnish full particulars on request.

FOR SALE

Advertisements under this head, $1.00 for 25 words or less for each insertion. Prepaid.

FOR SALE.—I have a telephone proposition which will interest any one of means who cares to investigate. This property is in fine condition; located in excellent field and paying. Write me at once. Box 270, care of AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 270

EXCEPTIONAL offer—I have a three-fourths interest in a telephone stock company owning four good exchanges and 1,000 miles of toll and farmer lines. About 1,000 telephones in operation and sufficient territory for that many more. Stock outstanding amounts to $50,000. Has earned over 30 per cent. in past two years. No competition; $25,000 cash and balance long time; low rate. Address Box 291, AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 291

FOR SALE—10,000 chestnut telephone poles in lengths from 25 ft. to 75 ft. Address E. F. Collins, 603 Ann street, Parkersburg, W. Va. 292

WANTED

Advertisements under this head, 25 cents for 25 words or less for each insertion. Prepaid.

WANTED—A good man for instrument work, who can also run wiring for electric lights. Address Box 287, care of THE AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 287

WANTED—First-class wire chief; magneto and central energy. Must fully understand installing multiple switchboards, etc. Address Box 288, care of THE AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 288

WANTED—Position with telephone company. I am an expert lineman and repair man; three years' experience; best of references furnished. Address P. O. Box 591, Toledo, Tama County, Iowa. 278

WANTED—Position as manager or superintendent of Independent exchange. Am temperate, married, and have had four years' practical experience. Address Box 273, AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 273

WANTED—To meet an investor with capital with a view to developing an automatic telephone which can be made at one-third cost of present automatic systems, also other telephonic devices. Exceptional opportunity. No agents or promoters need apply. Apply Box 272, care AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 272

WANTED—Position as superintendent of a large exchange or manager of a plant, 1,000 telephones or less. Have had ten years' experience in all branches of the business. At present am superintendent of an exchange in a city of 175,000 population. Open January 1st to any company that wants a hustler. Address Box 286, AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 286

WANTED—Position as manager with a first-class company looking for a hustler. Experienced particularly in toll and long distance work, including clearing house methods, and line construction. Familiar with every detail of telephone work. Executive ability; excellent references. Address Box 285, care THE AMERICAN TELEPHONE JOURNAL, New York. 285

Cyclopedia of Applied Electricity

Five volumes, 2,500 pages, 8 x 10 inches in size. ¼ Morocco Binding. 2,000 illustrations. Fully indexed. Regular price, $30.00.

Last chance at reduced price

We are printing an edition for our own use. By increasing the edition we can make a great saving in cost of manufacture. We are willing to share this saving with those who will place advance orders **immediately.** The regular price is $30.00. We will distribute 1,000 extra sets at the reduced cost of manufacture **while they last.**

$2.50 Paid Now secures this $30.00 Cyclopedia for less than half-price—$ 2.50—delivered, express prepaid. The full set of five volumes will be delivered to you as soon as it is off the press. Cut out the coupon below and mail to us. No further payments need be made until February 1st, when payment of balance at the rate of $2.00 per month must begin. **Order immediately.**

Books will be sent by express, prepaid, and may be returned at our expense if not entirely satisfactory.

Some of the Writers:

PROF. F. B. CROCKER, head of Department of Electrical Engineering, Columbia University.
PROF. WILLIAM ESTY, head of the Department of Electrical Engineering, Lehigh University.
H. C. CUSHING, Jr., Wiring Expert and Consulting Engineer, New York.
PROF. GEORGE C. SHAAD, University of Wisconsin.
J. R. CRAVATH, Western Editor of the Street Railway Journal.
CHAS. THOM, Chief of Quadruplex Department, W. U. Tel Co.
WILLIAM BOYRER, Telephone Expert and Consulting Engineer.
PROF. LOUIS DERR, Massachusetts Institute of Technology.

Partial Table of Contents:

VOL. I.—Electric Current; Measurements; Wiring; Telegraphy; Wireless Telegraphy.

VOL. II.—Theory of Dynamo-Electric Machinery; Direct Current Dynamos; Direct Current Motors; Storage Batteries.

VOL. III.—Electric Lighting; Railways; Management of Dynamo-Electric Machinery; Power Stations.

VOL. IV.—Alternating Current Machinery; Power Transmission.

VOL. V.—Telephony; Distribution; Construction; Cables; Cross Talk; Telephone Exchanges; Switchboards; Exchange Wiring; Operation; Maintenance; Common **Battery** System; Automatic **Telephony;** Systems; Faults; **Testing.**

COUPON--Cut out and mail

Enclosed find $2.50 for first payment on special sale of Cyclopedia of Applied Electricity. The balance ($10) I will pay in monthly payments of $2.00 each beginning February 1st.

It is understood that I may return the set at your expense within five days and that you will refund the amount paid. Also that you will return the $2.50 if my order is received too late.

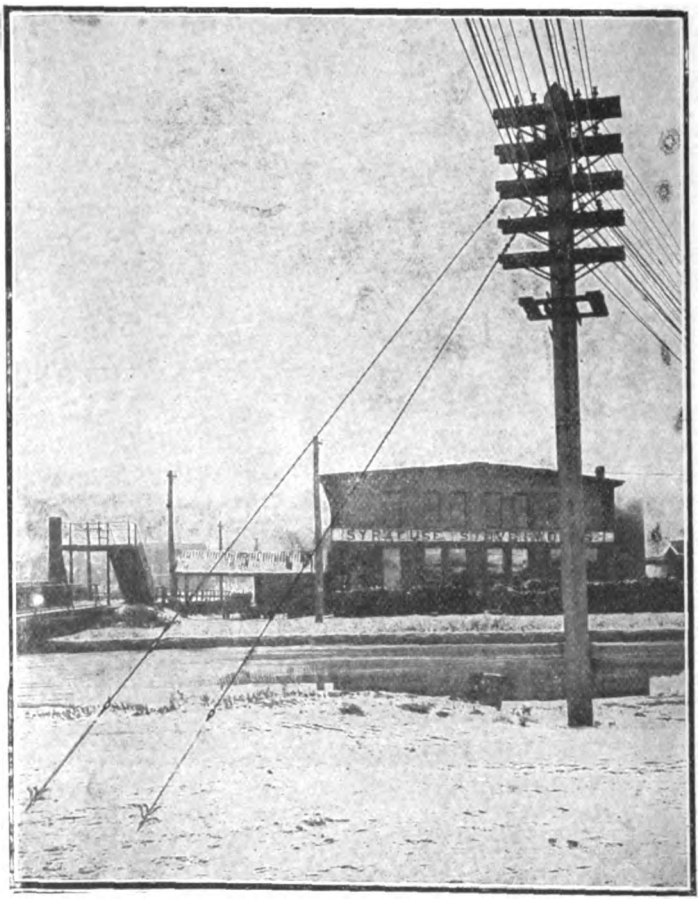
IN THE MANUFACTURING FIELD

"SUCCESS LIES IN THE KNOWLEDGE OF OUR TOOLS."

HARPOON GUY ANCHOR.

AN Anchor for guying telephone, telegraph and electric light and trolley wire poles, recently put upon the market, is that made by the Crouse-Hinds Company, of Syracuse, N. Y.

This Anchor is designed to take the place of the so-called "dead man" or "slug" and also to get rid of the trouble and expense met with in installing other kinds of Anchors. The method of installing is simple, as will be seen by the accompanying illustration. While the lineman is tieing the guy wire to the pole, the ground man makes a hole about 2½" deep by 4" in diameter with a digging bar, at the same angle that the guy will run. Placing the Anchor in the hole, he drives full length with an ordinary 12-pound sledge. The Anchor is then pulled out, by attaching it to the guy, until the wings spread, or about 6". The installation is now complete and the Anchor is ready for the guy.



Illustrating Use of Harpoon Guy Anchor.

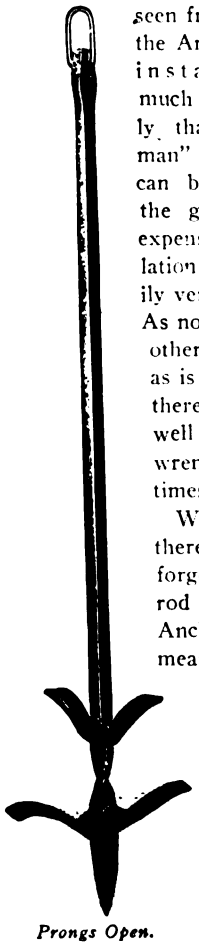
It can be readily seen from this that the Anchor can be installed very much more quickly than a "dead man" or "slug" can be placed in the ground. The expense of installation is necessarily very much less. As no wrenches or other special tools are required to install this Anchor, as is the case with every other Anchor on the market, there are none to be broken or replaced. It is a fact well known by those who have used augers and wrenches that they readily break and that oftentimes it is impossible to dig a hole with an auger.

With the Crouse-Hinds Harpoon Guy Anchor there are no tools to break. The Anchor is made of forged steel and is practically indestructible. The rod is 5 feet long and 1 inch square and the complete Anchor weighs 22 pounds. As the wings closed measure but 4" at the widest point, they do not prevent the Anchor being readily driven into the ground, and as they have a spread of 13" when open it would consequently be a matter of considerable difficulty to get the Anchor out of the ground after the wings are once spread.

In ordinary ground from 10 to 40 blows of the sledge are sufficient to install the Anchor. It will, however, go into any kind of wet, dry or frozen soil. It can be installed in many places where it is not possible to dig up the ground to bury a "dead man" or "slug," such as in a private lawn.

Before this Anchor was put upon the market, the manufacturers did considerable experimenting with very favorable results. Since then a number of telephone and electric light companies have tried it and report that it is in every way an entire success.

The Crouse-Hinds Company, Syracuse, N. Y., will gladly send specifications and prices to anyone interested.



Prongs Open.

Prongs Closed.

THE INTERNATIONAL TELEPHONE MANUFACTURING COMPANY, Chicago, it is said, is having a heavy demand for its new self-restoring drop switchboard, with the "never-failing" restoring device, and for its long-distance telephones. Among its recent shipments were switchboard equipments for Urbana Telephone Co., Urbana, Ind.; Mankato Citizens' Telephone Co., Mankato, Minn.; Wilmot Mutual Telephone Co., Cromwell, Ind.; Hackeman & Schroder, Jacksonville, Fla.; Rush Hill Telephone Co., Rush Hill, Mo.; Union Telephone Co., Divernon, Ill.; South Wayne Telephone Co., South Wayne, Wis.; Summitville Telephone Co., Summitville, Ind., and Jefferson County Telephone Co., Fort Atkinson, Wis.

THE BAIRD MANUFACTURING CO., 4 Michigan street, Chicago, gets letters every week from distant parts of the earth telling of the successful working of its pay-stations, and what a financial surprise they are. It is so much easier for all concerned to let the subscriber pay for what he gets, and let the telephone company have cash in the box for the service. If you don't believe it let the Baird Company send you a pay-station on trial.

FRANK B. COOK, besides getting an order for 8,000 pairs of his No. 444 Protector for the Citizens' Telephone Co., of Columbus, Ohio, has received the following orders for this popular type of Self-Soldering Protectors: La Harpe Telephone Co., La Harpe, Ill., 200 pairs; United Telegraph and Telephone Co., for their exchange at Newport, Pa.; a type L-3 frame of 100 pairs capacity equipped with 50 pairs; for their Littletown, Pa., Exchange, type L-3 frame, 100 pairs capacity, equipped with 50 pairs; Mangum Telephone Co., Mangum, O. T., type L frame, 300 pairs capacity, equipped with 260 pairs; Suburban Telephone Co., Ferguson, Mo., an addition of 60 pairs;

E. Ritter, Marked Tree, Ark., 100 pairs; Kellogg Switchboard & Supply Co., for the Telephone Exchange at Freeburg, Ill., 100 pairs; Scott Co. Telephone System, Oran, Mo., type L-3 frame, 100 pairs capacity, equipped with 60 pairs; Northeastern Telephone Co., an addition to the Lewiston, Me., Exchange, 150 pairs. Cook has also received an order from the from the Eastern Telephone Mfg. Co. for the exchange it is installing at Union, N. Y., for the York State Telephone Co. This order was for a type L frame of 300 capacity, equipped with 60 pairs of No. 444.

ENGINEERS OF DEAN ELECTRIC COMPANY.

IN the formation of the Dean Electric Company, of Elyria, Ohio, Mr. Dean associated with himself for the direction of its engineering department three young men who have already made names for themselves in the field of telephone engineering and literature. Ray H. Manson is a graduate of the University of Maine, class of '98, receiving a degree of Electrical Engineer from that institution. In 1899 he accepted a position with the Western Electric Company of Chicago, which he held for about two years, during which time he worked in the factory, shop office and telephone laboratory. He next allied himself with the Kellogg Switchboard & Supply Company as assistant to W. W. Dean in its experimental laboratory, and later served in its engineering department and as sales engineer.

Ray H. Manson, of the Dean Electric Company.

When the Dean Electric Company was formed the position as assistant to Mr. W. W. Dean in engineering and experimental work was offered to him, which post he now holds. He is an Associate Member of the American Institute of Electrical Engineers.

Albion D. T. Libby, of the Dean Electric Company.

Albion D. T. Libby is a graduate of the University of Maine, class of '98, from which institution he later received a degree of electrical engineer. In 1899 he entered the employ of the Western Electric Company, of Chicago, and after about two years in the factory, telephone laboratory, installing department, and engineering department, accepted a position with the Kellogg Switchboard & Supply Company to take charge of power equipment engineering. He spent four years with the Kellogg Company, designing all its power equipment, which included much original work. With the formation of the Dean Electric Co. he accepted the position of Power Engineer and Chief Installer of the Dean Electric Company in October of this year. Mr. Libby is an Associate Member of the American Institute of Electrical Engineers.

Sidney A. Beyland is a graduate of the University of Tennessee, class of '95, in electrical and mechanical engineering. After graduating he for a time was associated with telephone interests in Knoxville, Tenn., and Bristol, Va., going to Chicago in 1899 to accept a position in the drafting room of the Western Electric Company. Within six months he was assigned to the post of "checker" for the telephone department and later given charge of the circuit and cabling work, subsequently being placed in charge of the entire telephone department of the drafting room. This post he held but a short time, resigning to accept a position with the Kellogg Switchboard & Supply Company in its engineering department in charge of circuit and cabling work, and was assigned as assistant to Mr. Dean on apparatus design.

When the Dean Electric Company was organized at the first of the year, he accepted an offer from Mr. Dean to take charge of the switchboard engineering work of that company.

THE AMERICAN ELECTRIC TELEPHONE COMPANY has purchased a tract of land comprising about twelve acres, located at Sixty-fourth and State streets, Chicago, upon which it will erect a modern telephone and switchboard factory for the manufacture of all kinds of electrical equipment. The building and power plant will be of the most modern and approved construction, and will embody all of the latest ideas that have developed in this line. The factory will be built of vitrified brick, having two-story and basement frontage on State street and extending east with one-story saw-tooth roof brick building. Messrs. Nimmons & Fellows are the architects, and the general contract has been given to Jacob Rhodatz, one of the most reliable contractors in the city. The work of excavation and building was commenced some time ago, and the factory will be ready for occupancy upon April 1, 1905.

S. A. Beyland, of the Dean Electric Company.

THE FAIRBANKS-MORSE COMPANY, of Chicago, is manufacturing various types of dynamos and motors that have some very interesting features. A combination set for lighting is made in various capacities from 20 to 120 lights. In this type a gasoline motor is belted to a semi-enclosed ironclad dynamo, thus combining inexpensive cost of maintenance with a maximum of protection. Other units are made for both belt and direct drive up to 125 horse-power. For use in charging a semi-enclosed type E motor is suggested as using a small floor space and offering a large amount of protection against dust and dirt.

The company will be pleased to answer all queries with relation to its apparatus and will mail Bulletin 30 upon request.

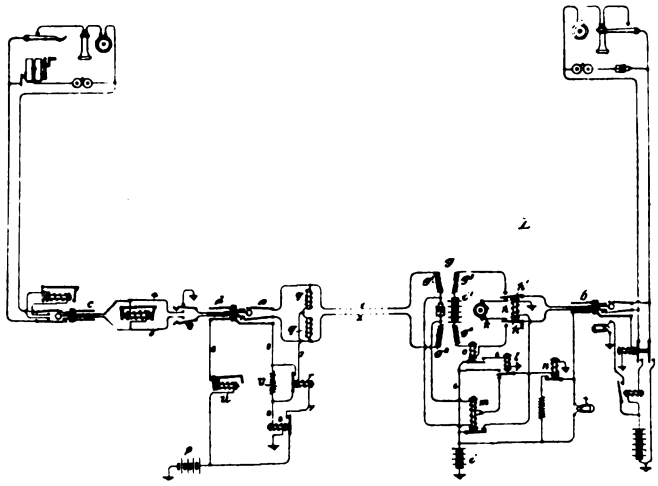
TELEPHONE PATENTS

RINGING CIRCUIT.

H. M. Crane, New York, N. Y., patents (No. 772,927). An improved ringing circuit for trunk lines, and assigns to the Western Electric Company.

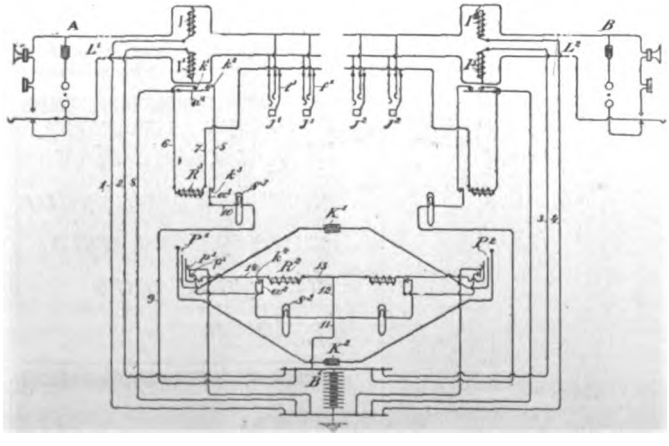
This invention is shown in the accompanying illustration and operates as follows: When the operator inserts plug *d* into jack *a* there is circuit from battery *p* through relay *s*, coils *q q* over both



sides of the trunk line through the differential windings of relay *m*; back contact of relay *l* relay *n* to ground, then relay *m* is not excited, but relay *n* is, and the supervisory *t* shunted out. When the *A* operator wishes to ring she presses key *e*, grounding limb *I*. Current from battery *q* divides at the coils *q q* on account of the ground on limb *I*. Hence relay *m* is excited, closes its contact, operates magnetic ringing key *h* and rings the subscriber.

CIRCUIT FOR COMMON BATTERY SWITCHBOARD.

H. T. Cedergren, of Stockholm, Sweden, patents (No. 772,782) an improved circuit for common battery switchboards. The object of this invention is to provide a circuit for a common battery switchboard, so arranged that the line relay controls the calling signal and the supervisory signals as well. This circuit is illus-



trated in the accompanying drawing. The armature a'' of the relay *l'* closes two contacts *k'* k^3 Wire *5* connects contact k^2 with receiving stud *k3* for armature of relay *R3*. The signal *S3* is thus connected with armature *a3* and with battery *B'* and control *k3* is joined to relay *r3* by wire *6* and wire *7* extends from relay to test springs *f'*. Armature *a* is connected with the other pole of battery *B'* by wire *8* and to earth. In the third conductor a relay *R3* is inserted, the conductor also running to battery. Armature *a2* of relay closes and breaks circuit through clearing out signal *S2* when plug *P'* is lifted and thus contact *p* controlled by plug is closed. Contact *p'* is hinged and has a spring tending to hold its lower end with contact *p2*, when plug *P'* is moved, connection with *p2* is broken.

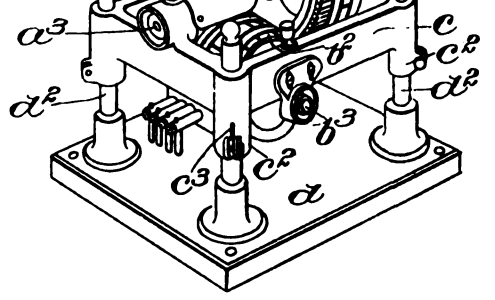
MOUTHPIECE PROTECTOR.

G. E. Grimm, Collingswood, N. J., patent (No. 772,286) and assigns one-half to J. J. Sleeper, Philadelphia, Pa.; an improved antiseptic attachment.

This is a device to protect the mouthpiece of transmitters. The inventor cuts out a circular disk of stiff paper, and punches a hole in the center, having thin paper ears, which clasp the transmitter mouthpiece and hold the disk in place. The hole in the paper disk is then covered with tissue paper soaked in any antiseptic. The disk may be thrown away and renewed as often as desired.

SIGNALING DEVICE.

D. M. Bliss, Brookline, Mass., patents (No. 773,187) and assigns to the Hottzer-Cabot Co., of Brookline, an improved signaling device. The object is to provide a self-contained apparatus to



operate one or more commutators, which may be attached to any source of signaling current, and transform said current in any way desirable for signaling. In the illustration *d* is a base plate supporting a frame *c* supporting the commutator aa^2, bb^2. A coupping a^5 is provided, whereby the machine may be attached to any motor that may be desired.

CUT-OUT.

J. R. Harris and C. A. Harris, Trenton, Mo., patent (No. 772,936) a telephone cut-out.

The object of this invention is to provide a cut-out for grounded lines to be used as a protection from lightning, and to enable two different lines to be switched together. The inventor provides a base plate, to which the line wires are attached by insulators, and on which there is a pivoted lever, to the center of which the telephone is attached. This lever is so arranged that it can connect the telephone to either line, or completely open the circuit. It is operated by a cord that extends from the base plate to the telephone.

THE WEEK'S MESSAGES

FINANCIAL.

HOT SPRINGS, ARK.—Barber and Brailey have sold out their interests in the local plant to Leo M. Flesh and his associates at Piqua, Ohio, who were interested with Barber and Brailey in the system.

STEWART, GA.—Stewart Telephone Co. has declared a dividend of 20 per cent.

KINGSLEY, IOWA.—The Kingsley Telephone Co. has increased its capital stock to $15,000.

MORRISTOWN, TENN.—The Citizens' Telephone Co. has increased its capital stock to $18,000.

McKINNEY, TEXAS.—The McKinney Telephone Co. will increase its capital stock from $10,000 to $20,000.

BRIDGEPORT, W. VA.—At a recent meeting of the Belmont Telephone Company, it was decided to call a special meeting for the 27th of December to discuss the increase in capital stock from $75.000 to $150,000.

FRANCHISES.

CRIPPLE CREEK, COLO.—M. H. Spear, general manager of the El Paso Telephone Company, has applied for a franchise in this city.

JERSEYVILLE, ILL.—The City Council has granted a franchise to the Kinloch Long Distance Telephone Co. of Missouri.

ESTHERVILLE, IA.—The City Council has granted a franchise to the Emmet County Telephone Co.

PORT DEPOSIT, MD.—The Town Council has granted a street franchise to the Martland Telephone Co.

NEW ULM, MINN.—Dr. J. H. Vogel, on behalf of the Blue Earth City Telephone Company, has applied for a franchise in this city.

ARGENTINE, MO.—The Home Telephone Co., of Kansas City, has been granted a franchise in this town for a period of twenty years.

MEXICO, MO.—The Mexico Ladonia Telephone Co. has applied for a franchise in this city.

BUTTE, MONT.—The Yellow Stone Park Tel. & Telephone Co. has applied for a franchise for a telephone system in this city.

MIDDLETOWN, OHIO.—The Middletown Home Telephone Co. has won its suit for a franchise to operate a telephone system in this city.

DALLAS, TEXAS.—S. A. Jones and F. B. McElroy have applied for a franchise to construct a long distance system to connect this city with outside points.

MADISONVILLE, TEXAS.—H. B. Huston has secured a telephone franchise for this city, and will build long distance line to connect with outside points.

LANDER, WYO.—D. G. Cahoon was granted a franchise for a telephone system in this city.

ELECTIONS.

WOODBURY, CONN.—The Waterbury Automatic Telephone Co. at a recent meeting elected the following officers: President, H. D. Curtiss; vice-president, A. D. Warner; treasurer and secretary, G. F. Harvey; superintendent and general manager, R. F. Harvey.

GARDNER, ME.—The officers of the recently incorporated Woodland Telephone Co. are: President, F. S. Collins, of West Gardner; treasurer, Jas. T. Collins, of Manchester; clerk, H. E. Emery, Manchester.

COUNCIL BLUFFS, IA.—The Council Bluffs Independent Telephone Co. has elected the following officers: President, E. H. Longee; vice-president, E. H. Merriam; secretary, F. J. Day; treasurer, E. G. Turner.

COMBINATIONS.

CLINTON, ILL.—The Farm & City Telephone Co. has sold its system to the National Telephone & Electric Company, which has bought the Farmers' Interstate Telephone system. B. F. Wasson, of Clinton, Ill., is president; S. H. Martin, of Waynesville, Ill., secretary and treasurer.

DIXON, ILL.—Dixon Home Telephone Co., recently incorporated with a capital stock of $125,000, has taken over the property and business of the Lee County Telephone Company.

LUTHER, MICH.—The Citizens' Telephone Co., of Grand Rapids, has purchased the exchange of the Luther Co. J. B. Prout will be retained as manager.

MARSHALL, MICH.—The Citizens' Telephone Co., of Grand Rapids, has purchased the telephone equipment of Dr. F. M. Foote.

FRED WAKEFIELD has been appointed manager of the telephone system at Lapeer, Mich.

SAMUEL STRONG has been elected secretary of the Home Telephone Company of Cohoes and Waterford, N. Y.

HARRY H. HART has been appointed manager for the United Telephone Company at Hanover, Pa.

MISCELLANEOUS.

SEDAN, KAN.—The Dosbaugh Telephone Company, with exchanges at Caney, Peru, Elger, Sedan and Cedar Vale, Kas., has finished cutting all its lines from ground to metallic circuits. This company has a territory seventy by seventy miles and about $85,000 invested in telephone property. It now has 1,000 subscribers.

LEWISTON, ME.—The loss to telephone companies due to the recent storm is estimated at about $150,000.

BAY CITY, MICH.—It is reported that the Valley Telephone Company, which operates exchanges in this city and Saginaw, will consummate a closer working agreement with the Citizens' Telephone Company of Grand Rapids.

DASSEL, MINN.—The Dassel and Collingwood Telephone Company has its new exchange in running order, long distance connections are made with toll lines of the Tri-State Telephone Company and two circuits are used.

LUVERNE, MINN.—The Beaver Creek telephone system has been connected with the Mead line which has its headquarters here.

MANKATO, MINN.—The Minnesota Valley Telephone Company now have their line open through to Herod Lake, Luverne, Brewster, Pipestone and Sioux City and Mitchell, S. D.

WATERVILLE, MINN.—The Cannon Valley Telephone Company now has five exchanges established at Elysian, Janesville, Montgomery, Le Sueur Center and Waterville.

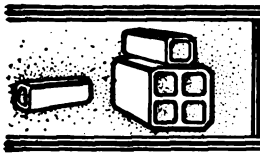
WINDOM, MINN.—The Windom Mutual Telephone Company is now in connection with Worthington, Luverne, Adrian, Sioux Falls and Pipestone. In a few days many other stations will be opened and during the month most of the towns of the Southwest can be reached over the Mutual connections.

GAINESVILLE, FLA.—The East Florida Telephone Company expects to extend its system to Tacoma, Wacahoota, Micanopy.

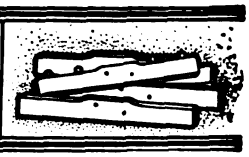
PEORIA, ILL.—The Interstate Telephone and Telegraph Company will install a new switchboard at once in this city.

CHARLESTON, ILL.—The Charleston Telephone Company will extend its lines to Salisbury.

STERLING, ILL.—The Interstate Telephone Company is building a long distance line to Rock Island from this city. A new line will also be built to Dixon which will give three circuits between the two cities.



New Construction in the Field



AMBOY, IND.—W. H. Meyers, manager of the Amboy Telephone Company, states that construction work will be done upon the system, and that an exchange will be placed at Converse next spring.

RUSHVILLE, IND.—Extensive improvements will be made to the line of the Rushville Co-Operative Telephone Company by J. F. Butterfield & Co., of Chicago.

FORT WAYNE, IND.—The Home Telephone Co. will extend its system into the rural districts.

DAVENPORT, IA.—A wire is being strung along the L. & I. R. R. for the installation of a telephone system.

DAVENPORT, IA.—The Union Electric Company will extend its toll system at once.

HARRIS, IA.—Dr. C. C. Cady and Otto F. Unz will construct a rural telephone line in this vicinity.

SIBLEY, IA.—A new rural telephone line is being constructed from Harris, Osceola county.

STEWART, IA.—The Mutual Telephone Company is considering a new exchange.

WEBSTER CITY, IA.—C. L. Briggs has been awarded the contract for the building of the Martin Telephone Company. J. R. White is architect.

LINCOLNVILLE, ME.—The Lincolnville Telephone Company will construct a four-mile extension to its system, and add several new subscribrs.

WILLIAMSBURG, MASS.—The Citizens Independent Telephone Company is erecting a pole line through the main street.

HOPKINS STATION, MICH.—The Citizens Telephone Company is improving the property which it purchased from the West Michigan Telephone Company.

OSTRANDER, MINN.—The Farmers Telephone Line will be extended from this village to Grand Meadow.

RICHWOOD, MINN.—A complete telephone line will be established during the coming year to Richwood, Callaway and the surrounding country.

SEAFORTH, MINN.—A telephone exchange is being installed here.

WALKER, MINN.—The Cass County Farmers Mutual Telephone Company will extend its telephone lines in the near future.

EMERSON, NEB.—A rural telephone line is being built west from here.

WESTBROOK, MINN.—The Southwestern Minnesota Telephone Co. contemplates installing an exchange in this city.

WATSON, MINN.—The Citizens' Telephone Company will extend its system in the near future.

KANSAS CITY, MO.—The Kansas Construction Company, which consists of the Home Telephone Company and the Barber and Brailey interests, will build additional long distance lines throughout the State to connect with the Home Telephone Company. Work has already been started.

BOZEMAN, MONT.—The Yellowstone Park Telephone and Telegraph Company has completed a line to this city, and will connect with Big Timber, Helena and Butte.

BLAIR, NEB.—The Blair Telephone Company has recently completed a new line west of this city.

DIXON, NEB.—John Mills and W. P. Truax are interested in a telephone company that will construct a system in this village.

SEWARD, NEB.—The Seward County Telephone Company will commence the construction of a local system at once.

HENNIKER, N. H.—The Henniker Telephone Company has extended its lines to Deering and Hillsborough.

CHESTER, N. J.—The Chester local telephone company will extend its system to suburban territory.

LEBANON, N. J.—The Lebanon Telephone Company is building a line to Flemington.

BUFFALO, N. Y.—The Inter-Ocean Telephone Company is installing a system in Geneseo.

PENN YAN, N. Y.—The Inter-Ocean Telephone Company is constructing a new line between this point and Watkins.

MT. VICTORY, O.—The Mt. Victory Telephone Company will construct several new lines this winter.

DOYBESTOWN, PA.—The Standard Telephone Company is constructing a through line from Quakertown to Philadelphia.

NEW ALBANY, PA.—The New Albany Telephone Company will construct lines from New Era, Bradford county, to Evergreen to New Albany and there connect with the New York & Pennsylvania Telegraph & Telephone Company; also from Overton, Bradford county, to Campbellsville, Eldredsville, Estrella and Forksville, Sullivan county. The directors are: Ray S. Wilcox, Rufus Decker and S. D. Sterigere, of New Albany; James J. Hannan and A. J. Bird, M. D., of Overton; Watson Fawcett, of Campbellsville; G. W. Heverly, of Sayre; G. A. Rogers, of Forksville, and George Horton, of New Era.

SHUKSHINNY, PA.—The People's Telephone Company will extend its line to Roosevelt.

WAYNESBURG, PA.—The Standard Telephone Company is making extensive improvements to its system.

WORCESTER, PA.—The Montgomery Telephone Company will extend its line to Norritonville.

CHAMBERLAIN, S. D.—Frank B. Roe has completed his line to Grand View and expects to extend it into Oklahoma.

EDGEMONT, S. D.—Hugh Houghton and five others have put in a telephone line from Hot Springs.

SHERMAN, TEX.—The Graystone County Telephone Company will build a line to Howe as soon as twenty subscribers are secured.

MONTPELIER, VT.—The Orange County Telephone Company will extend its lines to Berlin, Williamstown and Barre.

NORTHFIELD, VT.—The Northfield Telephone Company will make numerous extensions in the near future.

ST. JOHNSBURY, VT.—The Citizens' Telephone Company is extending its lines to West Danville and Danville.

THE AMERICAN TELEPHONE JOURNAL

Special Attention

The editor believes that every reader of this paper is vitally interested in the subject discussed this week on page 399.

As a special favor, therefore, he asks a careful reading of the matter.

He would like every reader of this paper to write him a letter expressing an opinion regarding this editorial.

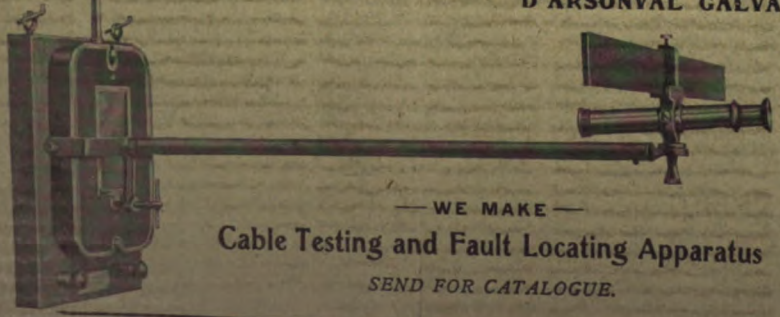
ELECTRICAL MEASURING INSTRUMENTS

D'ARSONVAL GALVANOMETER TYPE P.



Stimulated by the large demand for a good Galvanometer at a reasonable price, we have gotten out this instrument. It is well made, of finished workmanship, pleasing appearance and excellent working qualities. Its low price is due to good design, careful manufacture and production in quantity, and in no detail to poor material or slighted workmanship. It has the following desirable features: Simplicity of construction, attractive appearance, the moving system always entirely visible, a proportional scale, a damped system and quick working, strong suspensions that allow no zero shift, ample coil clearance and a sensibility that is ample for all ordinary electrical measurements and many precision measurements.

Do You Who Have Money Invested

in telephone systems realize that you are giving away about 25 per cent. of your service where you sell it on the privilege plan? One-fourth of the salaries of your operators, one-fourth of your maintenance expense, besides one-fourth of the many other expenses of your exchange, are donated to the deadheads, and your service is probably one-quarter less efficient. It's a vital question; treat it as such; and when you are ready to apply the remedy, don't forget that we can put up the prescription.

COOK'S SELF SOLDERING PROTECTOR

PATENTED NOVEMBER 29, 1904.

COOK'S NO. 444

I OWN OR CONTROL ABSOLUTELY THE ONLY PATENTS ON SELF-SOLDERING PROTECTORS WHICH HAVE ISSUED, AND UNDER WHICH APPARATUS IS BEING MANUFACTURED.

I invite a thorough investigation both of the patent situation and of the superiority of my devices. I am ready to furnish information or fill orders, guaranteeing not only satisfaction but protection, both legal and electrical.

Good business judgment demands that you use only protective apparatus on which broad patents HAVE BEEN GRANTED—not that on which an uncertain patent is pending.

Frank B. Cook. INVENTOR AND MANUFACTURER,

238 W. LAKE STREET, CHICAGO.

MARLIN CABLE HANGERS

The Reason Why

The buyer should buy our No. 3 Marlin Cable Hanger. Because it costs no more than makes that are shorter-lived and unreliable. We guarantee the material and the expected service of our Hangers—no one can do fairer—and our present big output is the result solely of the lasting reliability of our No. 3 Hangers. They never fall back on the guarantee back of them. We recommend the use of our best grade, the No. 3, as the truest economy. Guaranteed to be according to specifications of the A. T. & T. Co., made of three-strand Houselin, the best we can get, made of genuine selected American hemp, hand picked, hand laid, and specially well tarred. Hooks are No. 9 spring steel wire, **galvanized after being formed.** Practically rust-proof. Will stand a strain of 100 lbs. without opening. Write to-day for complete price-list of our three grades and various sizes.

A STUDY IN TRAFFIC.

By the Traffic Manager.

IT may perhaps seem forced to designate a telephone company as a transportation company, but in all essential points a telephone company is as much of a transportation company as one which operates railway or steamboat lines. A railway uses a track upon which trains of cars are drawn by means of a locomotive, that transfers from place to place loads of passengers and merchandise collected from various sources. A telephone company employs a track in the form of a wire, which extends from its central office to its various subscribers. Upon this track no physical locomotive actually runs; but, on the other hand, the telephone company collects loads of goods in the form of messages, which it transports over its track by means of the impalpable though no less real energy of the electric current.

For a railway manager to try and prosecute his business in ignorance of the number and size of his locomotives, and their capacity to haul loads, or the quantity of merchandise and passengers which the country through which his road extends can offer, would be the height of folly, and it is equally foolish for a telephone manager to attempt to operate an exchange in ignorance of the number and kind of subscribers which he serves, the quantity of traffic which they will daily originate, the capacity of his switchboard, the ability of his operators to handle the business delivered to them, and the loading to which his trunk lines will be subjected.

To secure the most successful operation of a telephone plant, the general manager must be thoroughly informed as to the following essentials:

First. The amount of traffic to be handled. Second. The possible capacity of the various pieces of apparatus whereby intelligence is transmitted. Third. The efficiency at which the plant from time to time actually performs it work. Fourth. The desirable efficiency, namely such a rate of loading as is on a whole found to be commercially the most advisable.

Evidently the answers to these questions can only be obtained from extensive experience. For, *à priori*, it is utterly impracticable to predict how many messages a subscriber will originate, or the number of calls that a trunk line may handle and still provide satisfactory service, or the load at which the various operators can work in a manner to win the subscriber's approval. So it is only by comparison of much experience, derived from many sources, that trustworthy information of this description can be obtained. Therefore, the traffic study is the most important problem presented to the general manager, and one which is never solved, for the progress of to-day is useful chiefly in indicating the improvement which may come to-morrow.

Fig. 1.

The actual originating business which the subscribers offer is the starting point of such investigation. It is essential to catalogue or index the various subscribers from all view-points, and determine the number of residence and business substations. The latter it is well to subdivide into various classes, such as newspapers, theaters, doctors, grocers, butchers, laundries, wholesale and retail houses of various kinds, lumber dealers and many other subdivisions which will naturally suggest themselves to the reader. Then the facilities which are supplied to each group should be registered, such as the relative proportion of party lines to single lines, and the various proportions of the different numbers of parties with which the party lines are loaded, also the relation between measured service substations and those upon a flat rate. Finally a description of the substation equipment is desirable, as indicating how many desk sets, extension sets, coin boxes, measured service meters, etc., are required to supply the demand of the various subscribers.

Where more than one central office exists in an exchange, such an inventory should be made for each one independently, and then these statistics may be tabulated as percentages of the whole, in order that, when complete, the manager may constantly have before his eyes a complete catalogue of the facilities with which the subscribers are working. Such information should be supplemented by a description of the central office and trunk line equipment, so arranged that constantly the relation between the subscribers and their facilities may at once be presented. It is often convenient to arrange such a description by plotting upon

Digitized by Google

a sheet of profile paper; this may conveniently be placed upon a pair of rollers contained in a glass case, in such a way that the sheet may be rapidly rolled to and fro so that the eye may traverse all of the curves, which indicate from time to time the relation between facilities and business. A system of colored inks and a combination of dotted and dashed lines may be used, which, when once memorized, convey at once to the eye the desired relationship. A record of this description soon becomes not only an invaluable history of the business in the past, but an unerring index of the probable growth which the future will demand.

The next operation is to ascertain the business which the subscribers offer, and concurrently the rate at which the various portions of the plant are working. Continued records of this kind soon reveal the desirable loadings to which the various parts of the exchange should be subjected in order to attain the best efficiency. Further, comparison of such information with similar data collected from traffic studies of other exchanges enables a manager to at once find out whether his apparatus is running under the most advantageous conditions, and if not, to point out a desirable remedy. It is highly improper to assume that the unit loads which studies of this kind reveal are final; they are not, they are simply statements of what the past has done, and indexes of what should be demanded in the future. They are useful in three ways.

First, to see whether from time to time the various parts of the exchange are working at such rates as experience has indicated advantageous, and if not, show what changes will produce an improvement.

Second, to determine whether the plant, as a whole, is working with harmonious co-operation; for the complexity of a telephone exchange is so great, and its organization so sensitive, that no one part can be seriously under or overworked without reacting upon all the other groups, and on the whole seriously reducing the efficiency.

Third. Telephony is constantly evolving new methods in both apparatus and in operating; and, unless these are tested in the inexorable mill of experience, it is impossible to tell whether such devices result in good or in evil.

In certain classes of transportation business records of traffic become automatic. Thus with railway and steamer lines, freight is prepaid by weight and distance, and a consultation of the waybills immediately indicates the business which is handled from day to day, and the profits which accrue. The passenger record is easily obtained by consulting the number of tickets which are sold, as this indicates at once the number of passengers carried and miles each is hauled, and the receipts derived therefrom.

In a telephone exchange, however, even when equipped with measured service, statistics of traffic do not automatically record themselves, so special investigations are from time to time essential in order to obtain the data required. The customary method requires a count to be made of the number of originating calls and trunk messages which are handled at every switchboard during a given twenty-four hours. The ordinary practice is to make a count of this kind monthly, and in addition upon such holidays and other special occasions as may seem to demand extra investigation. The earliest method adopted was to provide each operator with a wooden peg, similarly shaped to the ordinary plug, so that it might be placed in a jack. The plug is provided with a head which will prevent it from entering too far and becoming lost. The operators are taught to use the set of 100 multiple jacks nearest in front of them. The count is usually commenced at midnight of a given twenty-four hours, and all operators instructed to place the peg in the zero jack of the bank, and then move the peg along one jack, for every call that is received, the moment the subscriber's signal is actuated. At the end of each

hour a supervisor visits the board, and upon a proper blank makes record of the number of the jack in which the peg stands, and then replaces it to the zero hole, thus securing a record of the number of calls which have originated in each position during the hour which has preceded. Owing to the use of the wooden peg studies of this description have been termed "peg counts." Many methods of taking such records have been proposed as improvements on the peg.

The simplest is, perhaps, the substitution of some mechanical device, such as a street car register, bicycle cyclometer, or a revolution counter. Then it has been proposed to equip each cord with some sort of a mechanism which should automatically register every time that it was used. But as the operators are likely to hold the cords in their hands, no such device has as yet been successful.

For long distance and toll line switchboards, or in cases where the operators are required to make a ticket for each call, the traffic record becomes very largely automatic, and may be collected at any time by counting the number of tickets which have been used. When lines are supplied with measured service meters located at the exchange, an hourly inspection of such meters will at once reveal the desired statistics, but, if the toll counters are placed at the substations, it would be an impossible task to inspect each.

Experience has shown that it is essential that operators should not be aware of the number of calls which other operators have recorded, or otherwise those that are lazy and inefficient will compare notes with the more industrious, and stuff the record to such an extent as to make it unreliable and untrustworthy. It is often thought that the labor of making a record of this, kind would inflict such a burden upon the operators as to interfere with proper service. This is not the case, for presently the operators become so experienced that the subscribers never know that a peg count is in progress. And furthermore, the spirit of emulation is soon so cultivated that the operators become desirous of having peg counts taken, in order that from time to time their improvement may be noted, and brought to the attention of the company.

In any method of collecting statistics, the supervisor is supplied with a blank, a customary form being shown in Figure 1, and opposite each hour a record of the number of originating calls in each position is placed. When the count is finished these records are transmitted to the traffic department, and placed in the hands of employees equipped with tabulating machinery, such as slide rules, adding machines, book typewriters, etc., whereby the records from each office are quickly collected and tabulated in such a manner as to be useful in determining the loading to which each portion of the exchange is subjected. Many methods for arranging data have appeared from time to time, but the present tendency is towards a method of exhibiting the results of each position in each office in detail upon a sheet precisely the same as that shown in Figure 1. Then a summary sheet is made containing each item for all offices, so collected as to present a complete and comprehensive record of the whole. Finally the various detail sheets, headed by the summary sheet, are collected and bound in book form, making a complete traffic record.

A blank suitable for a summary sheet is shown in Fig. 2. Each item is prefixed by a given number indicated in the extreme left hand column, the next column shows the various items, which are subdivided into nine sections; the next column shows the arithmetical derivation of the items; that is to say, the arithmetical method whereby the various quantities in the other columns are obtained.

The rest of the table is made of sufficient size to devote two columns to each of the subsidiary offices, the first one of which shows the returns obtained from each office on the particular day of the peg count; the second shows the difference, whether greater or less, than the preceding count. The table may be either extended or contracted so as to give any desired number of offices, and any of the sections may be omitted or curtailed to such a degree as the business of the particular exchange under consideration shows to be most desirable. Lastly, at the extreme right a column is placed giving the totals for all offices, and the corresponding differences, giving a comparison with the preceding enumeration. To economize space the various items which are suggested for column two are shown below. By this means any manager may readily arrange the account to suit his convenience.

It is useful to complete the record by printing it with a book typewriter upon tracing muslin; then the cloth so prepared may be placed in a blue print frame, and as many copies quickly obtained as is desirable. It is advantageous to prepare so many copies of each peg count as may be necessary, so that each manager and all of the principal officers can be supplied with the information which it contains. Then from time to time a meeting of the managers and other officers is convened to discuss the results which the peg counts have shown. From such conventions the attention of the various officers is forcibly directed to the actual results which the service shows, and many highly valuable suggestions are elicited that look toward an improvement of the business.

Some exchanges have found it useful to plot the results of the peg count upon section paper; and, while this does not give so searching or so minute an analysis, it depicts in a manner that appeals more forcibly to the eye than any possible tabulation of figures.

Examples of this kind showing the results obtained in different exchanges will be illustrated in a future article, in which information gathered from companies operating in cities of various sizes will be given.

THE PRIVATE BRANCH EXCHANGE AS A BUSINESS BUILDER

ARTICLE V. CIRCUITS AND THEIR OPERATION.

BY A. DALLAM O'BRIEN.

THE connecting cord circuit is subject to considerable modifications in boards of the various manufacturers, and no particular circuit can be said to be a standard. With most methods of wiring the cord circuit, two supervisory signals are employed, in order that either the calling or called substation may be able to signal the operator. This, however, does not always hold, as in some cases, in operating private branch exchanges, the switchboard operator is governed entirely by the supervisory signal in the answering cord; or, in other words, the duration of the connection is wholly dependent upon the calling substation.

The circuit shown in Fig. 4 is adapted for use with common battery switchboards and differs from the circuit described in a previous article only in the fact that in the former case a repeating coil was employed in each cord circuit, while in this case the repeating coil is replaced by a retardation coil, the remaining portions of the circuit being identical in the two cases. The retardation coils, which are used for this work, consist of a closed iron core, which is usually made up of a bundle of small iron wires, upon which are wound two coils, each having a resistance of from 15 to 20 ohms. The number of turns in these coils is comparatively speaking, large, and their effect is to offer a high impedance to the currents caused by the varying potential at the buss-bars at the branch exchange and to prevent cross talk or interference when two or more connections are made through the board at the same time. Probably one of the most important considerations, in connection with a common battery branch exchange, is the means to be employed for furnishing the current to the switchboard.

This may be accomplished in a number of ways. In some of the earlier installations the battery was furnished to the buss-bars, which were mounted on the switchboard connecting rack

Digitized by Google

from a group of Fuller cells located at some convenient point within a few feet of the switchboard, and, to some extent, this method of supplying current is still employed. In recent installations it has been the common practice to replace the Fuller cells by a small storage battery, which has a discharge capacity large enough to run the board for a period of twelve hours. These batteries must receive their charge from some outside source of current, and this may be readily accomplished by using one or more pairs of wires from the central office and charging the batteries at the branch over these wires.

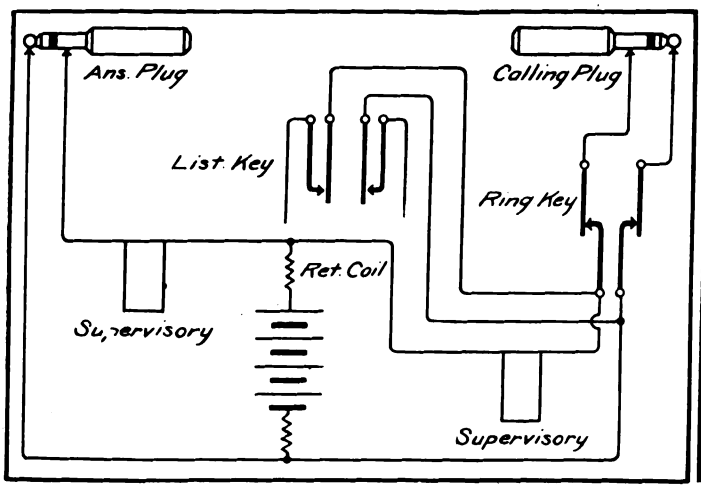

Fig. 4.

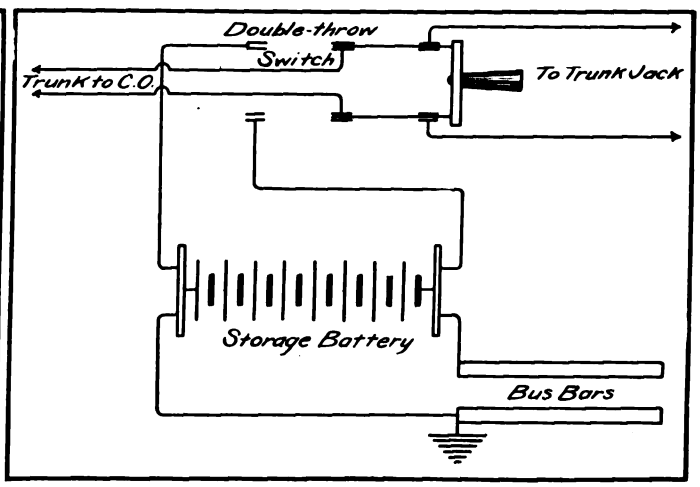

Fig. 5.

The number of pairs that are necessary for this purpose in any given case will depend upon the size of the conductor; the distance from the central office to the branch exchange and the voltage which it is desired to obtain at the branch. It can easily be seen that cases may arise where the distance from the central office to the branch becomes so great that an excessive number of conductors would be required to charge the batteries and at the same time prevent too great a drop in potential due to the resistance of the line. In such cases the branch batteries may be charged from a direct current electric light or power circuit, sufficient resistance being inserted in the circuit so as to reduce the voltage of the current passing through the battery to the desired value. While this method entails a considerable loss of power, yet at the same time it may often prove less expensive than would the employment of a sufficient number of conductors, in order to charge the batteries from a central office. Where the branch exchange is an unusually large one, it may prove advisable to install either a motor generator set or a small gas engine and generator and thus charge the batteries direct.

With small boards, the operator is very often able to handle all the connections which must be made through the board, and also provide the ringing current by using a hand generator which is wired to the ringing keys, but it is obvious that where the volume of traffic which is handled through the board is at all large that manual ringing is out of the question, and in the modern installation where an operator is employed this condition is almost invariably obtained. The general practice for furnishing the ringing current is to supply it to the branch over a pair of conductors from the central office, both wires of the pair being connected to the non-grounded side of the central office source of ringing current, the return being obtained by means of a ground at the branch exchange. In addition to this source of supply, provision is invariably made so that a hand generator may be used in case of an emergency, due to an accident, to the power lead from the central office.

Where the branch exchange is one that is not used to any great extent during the night, the charging of the storage batteries may be easily and economically accomplished by using the trunk lines between the central office and branch as a medium over which to send the charging current, this, of course, being done during the night. It is only necessary where this is done to provide a switching device, both at the central office and at the branch, so that the trunk lines may be connected to the proper sources at either end.

The method in which this may be accomplished by using a trunk line as the conductors for the charging current is illustrated in the diagram in Fig. 5. The incoming trunk line from the central office is connected to the central contacts of a double throw switch, the remaining pairs of contacts being connected to conductors leading to the storage battery and to the trunk jack, respectively. The operation of this circuit is readily apparent from the diagram.

As regards the traffic operation of switchboards of this character, there is little that need be said from the branch exchange end, as all the complication, if it may be dignified by that name, is placed upon the central office. It is, however, a most excel-

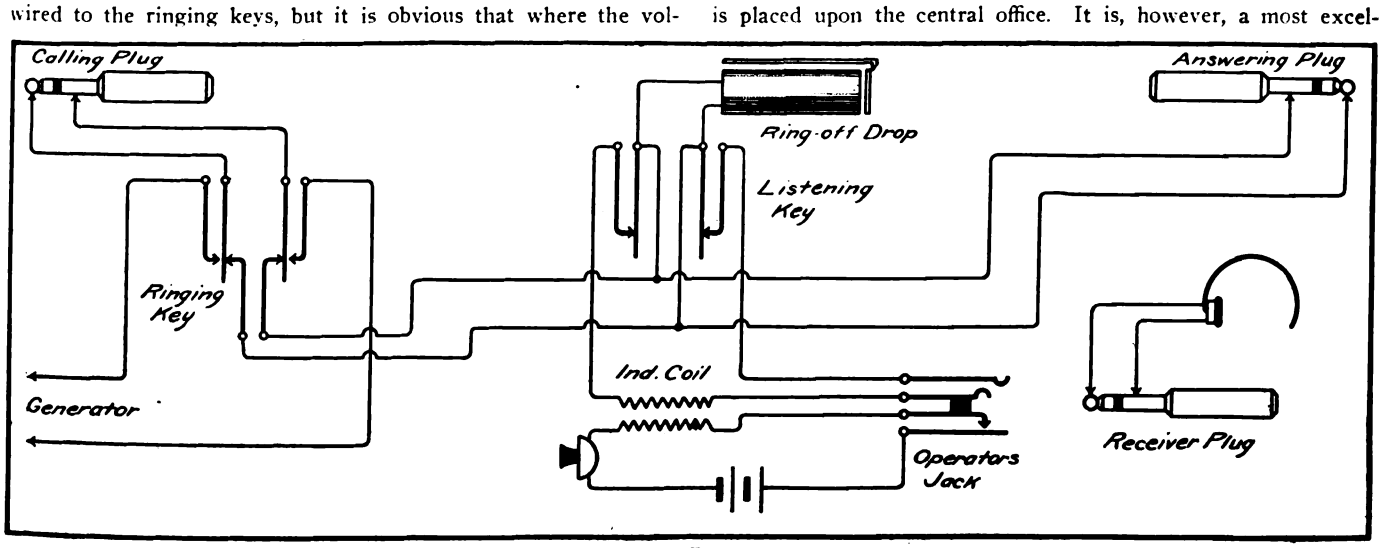

Fig. 6.

Digitized by Google

lent practice where a branch exchange is equipped with ten or more trunk lines to the central office to divide these lines into two groups, one of sending and one of receiving trunks, and to impress upon the operator at the branch exchange that under no circumstances is an originating call at the branch for a point reached over a trunk line to be completed over a receiving trunk unless all of the sending trunks are busy; and in the same way, the operators at the central office should be instructed that upon receiving a call for the branch exchange the sending trunks should be tested first and one of these used, if possible, and if all are found busy, the receiving trunks may be tested until an unused trunk is discovered.

By this means the central office operators are not often called upon to test a large number of trunks before finding one which is disengaged, and thus time is saved where time is valuable.

The branch exchange operator is usually fortunate in not being burdened with the necessity of making checks and keeping a record of the calls which pass through the switchboard, except on calls which are handled over trunks to the central office, and in such cases, a record is only made for the purpose of furnishing either a check upon the business transacted from the branch substation or else furnishing a check upon the number of calls completed over the lines of the telephone company.

On the part of the company, it is necessary for the efficient operation, for this class of board, that an accurate record should be kept of the number of originating calls at the branch exchange, which are handled over the trunks to the central office, and it is also important that a record should be kept of the number of trunked calls for the branch exchange, which are delayed, due to the fact that all of the trunks are busy. With this information at hand, the growth of each particular installation may be carefully and accurately followed, and thus the company be in a position to intelligently convince the subscriber, to the branch exchange, of the necessity of greater trunking facilities between the branch and the central office. Where the magneto type of switchboard is used for private branch exchange work there are few, if any, complications which arise.

Each substation is supplied with its own local battery, usually dry cells, and the instruments are directly connected to the switchboard jacks, the line signal usually being a high impedance drop which is permanently bridged across the line. A typical cord circuit for this type of installation is illustrated in Fig. 6. In this arrangement the calling plug is equipped with a ringing key and the connecting cord circuit consists of a perfectly straight circuit between the two plugs. A listening key is bridged permanently across the cord circuit and a high impedance ring-off drop connected through the long springs of the key. The operation of this circuit will be easily seen from the diagram.

The Telephone in the Courts

Conducted by A. H. McMillan.

Readers are invited to submit questions on any point of Telephone Law. They will be answered and explained on this page.

ALLEGED DISCRIMINATION.

THE Twin City Telephone Company has brought suit for an injunction restraining the city of St. Paul, Minn., from further destruction of poles and wires of the company along Hague avenue. In its answer to the proceedings for a temporary injunction and the call for an answer why the injunction should not become permanent the city cites the various orders of the common council, the correspondence between the city officials and the company, the orders for the building of the conduits for the wires, the actions taken by the residents of Hague avenue and the dangers and inconveniences attendant upon the maintenance of the poles and wires.

It is stated in the answer that the cross arms and wires are almost directly in front of and on a level with the windows in the upper stories of the dwellings adjacent to the poles and that on account of the wind storms which are so common in St. Paul and the fact that the wires are constantly charged with electricity the people living in that vicinity are in constant danger of the poles being blown onto the house or into the street. In windy weather the wires make a loud, disagreeable and annoying noise which can be distinctly heard for a long distance, and it greatly disturbs the people living on that street.

The company in its reply to the answer states that the wires and poles in question were erected because the company believed in the force and intent of the ordinance allowing them to be placed there and that as their removal would cause great additional expense to the company the action of the council in so ordering was unreasonable.

The toll lines on the poles were being used to their full capacity and with slight repairs would have answered the purposes of the company for ten years.

The defense is made that the conduit system is too costly and that it is not necessary west of Dale street, a part of the city that is sparsely inhabited. If the company is required to place the wires underground, it ~~is said that~~ the work could not be done in less than six months, and that if ordinary delays are to be taken into consideration, two years would be a reasonable time in which to construct the conduits and put the wires underground for the half mile.

The company further says that if the city possesses the power to order the wires of the company underground on Hague avenue, it also has the right to order wires underground in other sections of the city, and if such is the case, it would be useless for the company to attempt to maintain its business in St. Paul. Such action is declared to be an unwarranted discrimination as between the Twin City and the Northwestern companies, and the declaration is made that if the city persists in its present attitude it will be necessary for the Twin City Company to withdraw from St. Paul and leave the field to its competitor.

ACCOUNTING IN A TELEPHONE CASE.

MAYOR P. J. LUCEY, of Ottawa, Ill., has filed a bill of complaint against the Streeter Telephone Company and certain of its members. He alleges that the cost of constructing the exchange was approximately $125,000, for which amount bonds were issued and deposited with the American Trust and Savings Bank, of Chicago, and that the financial interest of the complainant in the company amounts to $10,000. He alleges that subsequent to depositing the bonds with the Chicago bank, the president and vice-president obtained possession of a large proportion of them, some $115,000, and now threaten to sell or dispose of them, which act the complainant says would be greatly to his injury. The company, he says, has no substantial indebtedness and does not owe either the president or vice-president anything. To restrain them from making the sale threatened and prevent the injury to his interests he asked and was granted an injunction against the defendants. He prays for an accounting on the part of those who have possession of the missing bonds.

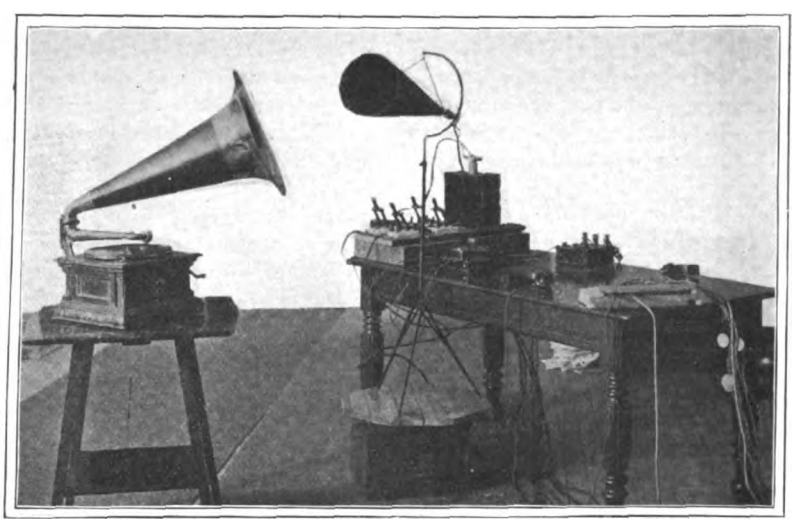
HOW THE KEYSTONE FURNISHED THE ELECTION RETURNS

By Frank C. Ogden.

THE Keystone Telephone Company in conjunction with the *Evening Telegraph*, of Philadelphia, made a very unusual arrangement to distribute the election returns, and so successful were the methods employed that the subscribers to the service knew the results in many instances ahead of all others relying upon other news agencies. This triumph of the Independent company was brought about by a thorough investigation of all methods heretofore utilized and then from the best of all the results herewith described were attained. Compared with the other means employed by other companies the Keystone's method was simplicity itself and enabled a service to be given that was quicker and better than could have been possible with the complicated circuits and apparatus employed elsewhere.

The general arrangement of the distributing apparatus is shown in the accompanying illustration, which will give a good idea of the scheme evolved.

Numerous tests were made to settle upon the best transmitters and the best arrangement of transmitters, and finally an American transmitter was selected and the best results obtained by mounting it on the end of an ordinary phonograph recording horn, with the back of the transmitter open. The transmitter used was one out of regular stock (in fact, it had been in service in a subscriber's office). In the preparations for this special service it was not found necessary to employ any instruments or materials that were not in ordinary use by the Keystone Company except the phonograph horn and a large Victor talking machine that was used to send out music over the circuits, so that there would be no tiresome waits between bulletins.



Apparatus Employed to Distribute Election Returns by the Keystone Telephone Co., of Philadelphia.

The bulletins were received over special wires from the office of the *Evening Telegraph*, which paper placed its entire news-gathering facilities at the company's disposal. The bulletins were written in duplicate, one copy going directly to the man operating the transmission circuit, the other copy going to the typewriters for duplication.

The circuits were so arranged that all the returns and music were sent out from one transmitter to all subscribers that wished to hear the returns. There was absolutely no relaying of bulletins. In addition to the lines in Philadelphia, connections were made on the same circuit to Wilmington, Delaware; Trenton and Atlantic City, New Jersey, and the intermediate towns, over the wires of the Keystone State Telephone Company.

As a matter of precaution, two circuits were prepared, differnections were made to Baltimore, Md.; Harrisburg, Pa.; Atlantic City, N. J., together with quite a number of the intermediate towns, in addition of several hundred stations in Philadelphia. The transmission was perfect, the music being especially fine.

As a matter of precaution, two circuits were prepared, differing slightly in detail. In the preliminary tests both circuits gave equally good results. On Election night, when the load came on, it was unexpectedly heavy owing to the rain (in some of our exchanges as high as 70 per cent. of the lines were connected at one time). It was found that much better results were obtained from one circuit than the other, and for the rest of the evening the same transmitter was used, it being in constant use for four hours and forty-five minutes, and was only cut out then as the service was closed at 1.45 A. M. The especial election service began at 7 P. M. and lasted for six and three-quarter hours, during which time a continuous stream of bulletins interspersed with music was sent out.

In addition to this general service, special questions were answered by the *Evening Telegraph* information bureau—Main 18-00—by twenty operators, in connection with a special information bureau located at the telephone office with a duplicate equipment with twenty operators, special arrangements being made so that each of the operators could disconnect his instrument from the switchboard, leaving the plug hanging in the air in front of an operator that did all the plugging. This arrangement made it possible for the twenty operators to be located in any part of the room. These forty operators did nothing but answer special questions relative to the election.

A return circuit was tapped on the subscribers' circuit at each exchange and brought back to a strip of jacks in the transmitting room, so that it was possible for the person in charge to tell just what the subscribers were getting and how the transmission was keeping up. In the same row of jacks was tapped the outgoing circuit so that the superintendent could listen to the transmission and be thus enabled to instantly remedy any defects which might occur.

When a subscriber asked for "election returns," he was asked whether "general" or "special" returns were wanted. If "special" were desired, connection was made with the information bureau, Main 18-00. If "regular" returns were asked for, the subscriber was plugged into a multiple jack connected with election returns circuit and left there as long as the subscriber kept his telephone off the hook. As soon as he hung up the operator disconnected him in the regular way. In this way the subscriber was not cut out of the regular service, but could get the operator at will.

In the service giving out "regular" returns there were used two receiving operators and one transmitting operator, with reliefs, the wire chief of each exchange being on duty to look after trouble.

The *Evening Telegraph* also furnished the returns to twelve of the principal theaters in the city as well as the large hotels, and at the same time displayed the news upon large canvases at seven of the most important points throughout the city.

Although it would be impossible to give the actual number of calls made and answered over the Keystone lines, yet a fair estimate would place the number in the neighborhood of 75,000. This does not include the out-of-town service or the special calls for news other than election.

The people of Philadelphia in every instance praised the methods employed and complimented the Keystone Company and the *Evening Telegraph* for the celerity shown in furnishing the returns.

CONVENTION OF THE INTERSTATE ASSOCIATION.

THE annual convention of the Interstate Telephone Association will be held at the Auditorium Hotel in Chicago on Tuesday, Wednesday and Thursday of next week. The chief interest attaching to this meeting will be in connection with the movement that was started in St. Louis, at the convention of the National Association, looking to a merger of the two organizations. Should this movement fail, it will be the duty of every telephone operator who has the interest of the Independent movement at heart to hold the men responsible for such a failure, to a strict accountability.

THE AMERICAN TELEPHONE JOURNAL has assurances from the leading spirits in the National Association that, on their part, no stone will be left unturned to bring about such a merger; that every reasonable concession will be made to the Interstate Association, and that there will be no self-seeking. In other words, we are assured that the only conditions to be laid down on the part of the National Association representatives will be simply of a nature to insure the creation of a working national organization, one that will be useful to the telephone industry.

If the suggestions of the National Association people are met in a responsive manner by the representatives of the Interstate Association at the Chicago convention, there ought to be no difficulty in bringing about an organization under one head, and to set in motion a force that will at last secure an effective machine; that will do for the Independent industry what their national associations are doing for the light and power men, for the bankers and other representative business men of the country. These men have found their most effective weapon to be a strong, central, business-like organization, that works 365 days in the year for the benefit of its members throughout the country. Because of the results obtained by these other associations, the members everywhere have cheerfully contributed for years, both in time and money, to the work; and it requires only the most limited inquiry to find that the members of these other national associations have been repaid tenfold for their investment.

Unfortunately this cannot be said for the telephone industry; so far no tangible results have been obtained by either of the Independent organizations. However, the movement started in St. Louis at the September convention of the National Association has already shown tangible results in the way of an aggressive campaign of organization; and it is our firm belief that this movement will with proper co-operation bear satisfactory fruit.

We deem it the duty of the representatives of the Interstate convention to aid this movement in every way in their power, and to bring about at the Chicago convention unanimous action that shall result in the strengthening of this healthy activity that has set in. We have no sympathy with the prophecy that the Interstate will set its face in opposition, and that some of its leading spirits will, from motives of their own, work not for amalgamation, but for continued opposition. We prefer to believe that the Interstate people have the welfare of the industry just as much at heart as the members of the National, and that they will do everything in their power to bring about co-operation. Should this prove to be untrue, should the leaders of the Interstate Association work against union, they will, in our judgment, make it very clear that they have placed their personal interests above the interests of the Independent movement, and we shall deem it our duty to inaugurate a vigorous campaign for their extinction.

THERE MUST BE NO FAILURE TO AMALGAMATE.

The Interstate Association in the past, as we pointed out several months ago, has given no indication that it is qualified, as at present organized, for the effective work to be done. It has not taken advantage, even in a limited sense, of the opportunities that were presented to it to bring about a cohesive movement. Instead, some of its officers have worked along exactly the opposite lines, fomenting strife within the ranks, instead of training the guns on the enemy. They have put out literature that had a distinct tendency to create ill-feeling, instead of solidifying all of the Independent interests. The Association can hardly point to a single achievement looking to the welfare and betterment of the industry. It has merely given us, in and out of convention, simply talk. And none of this talk has injured the common enemy, while a great deal of it has engendered bitterness among the men who must stand shoulder to shoulder if the Independent cause is to thrive. Even the least thoughtful men in the telephone business must see that the time has arrived when the Independents are fairly driven to act in unison; when they must bring about the creation of a central organization that shall do something practical and helpful.

The action of the Bell Telephone Company makes this so clear that it hardly needs emphasizing. The enormous strength which the Independent movement has developed has finally opened the eyes of the Bell interests to the facts as they exist. The Bell people finally realize that they cannot compete on an even basis with the Independents, and that the tactics of the past no longer avail to crush out opposition. On the other hand, there is evidence that the Boston organization is training its vast machinery for a new and systematic attack on its competitors. A striking evidence of this is to be found in New York City. Here, in the offices of the American Bell Telephone and Telegraph Company, elaborate maps and statistics, showing Independent conditions within a radius of 100 miles of New York City, have been carefully compiled. The maps and statistics show the exact territory covered by every Independent company, giving the name of the company, route of line, number of circuits, whether copper or iron, grounded or metallic. There is also complete tabulated information giving the number of stations, switchboards, switchboard capacity, number of miles of aerial and underground cable, number of ducts and all other information pertaining to the physical condition of the Independent plants. There is also to be found detailed information as to franchises granted and franchise conditions, rates, long-distance lines, the financial condition of the various companies, and a list of their officers and principal stockholders. Similar information and on the same thorough and elaborate scale is, no doubt, to be found in every other division of the Bell Company's long-distance offices, so that the Boston people know almost to a dot the exact facts relating to their competitors in all parts of the country.

What a powerful weapon this is any schoolboy can realize. To meet such conditions successfully the Independents must have a similar organization, through which statistics like these can be gathered and kept available in a central headquarters. It is therefore absolutely essential that there should be one, and not two, national organizations in the Independent field, and it is the duty of the Interstate's representatives to meet the national movement inaugurated at St. Louis at least half way. There must be no failure in the amalgamation movement this time.

WHERE IS THE FOOL KILLER?

EITHER the Bell literary workers have lost their cunning, or the Chicago police are remiss in their duty towards society, by permitting the author of the latest "Monster Telephone Combination" story to roam the streets without a keeper. In either event, the Fool Killer has some terrible work to do among the Chicago editors who gave publicity to the following in the daily papers of last Monday:

A scheme which is the preliminary step to the organization of a gigantic telephone trust which, when its alleged purpose is accomplished, will involve a capital estimated at $700,000,000 and which will put out of existence all Independent telephone manufacturing companies in the country, came to light in Chicago yesterday with the announcement that a representative of an Eastern syndicate was endeavoring to obtain options on all Independent factories in the city and obtained a few.

Similar options are being sought from all the Independent telephone manufacturing companies throughout the country, with the object of forming a big combination of manufacturing telephone interests on about the same order as other large corporations, such as the United States Steel Corporation, in order to eliminate competition in this line.

While the syndicate is said to be composed of Eastern bankers, it is believed among the Independent people that Bell interests are behind the movement. The latter theory, according to a well-known Independent manufacturer, is based upon the fact that a similar attempt to eliminate competition was made several years ago, when the Bell interests absorbed numerous Independent telephone manufacturing concerns. This plan failed, however, for as long as there were Independent telephone manufacturers in the field, it was conceded, there would be Independent operators.

Hence the only plan by which competition could successfully be eliminated was by consolidating the various Independent manufacturing plants of the country, thereby cutting off the source of supply for the Independent operators.

W. J. Hilands, of Chicago, who is said to represent Eastern parties in the movement, declared that the proposed combination had proceeded so far that there was very little doubt about its consummation. Mr. Hilands denied, however, that he was directly interested in the deal, but said he had been assisting a friend.

Why the sponsor for this charming yarn should have stopped at a little capitalization like seven hundred million dollars seems hard to determine. Seven thousand millions would have sounded ever so much bigger, and would have been quite as reasonable.

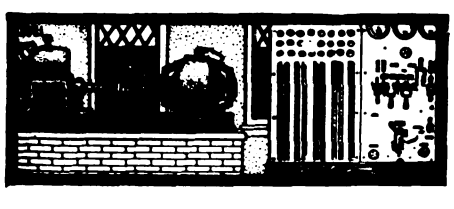
The facts in the matter are these:

A stranger called on every telephone manufacturer in Chicago, and left "option blanks," to be filled in at any old figure that might be desired. Not a single manufacturer signed these blanks, and the "promoter" was never again seen.

That was as far as the "consolidation" went and that is all the foundation for the story which was carefully telegraphed out of Chicago to every city in the country.

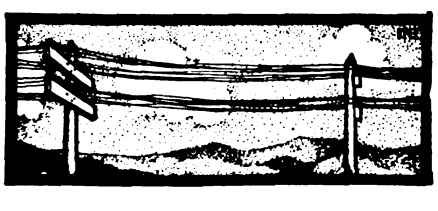
The manufacturers are inclined to look upon it as an attempt by the Bell to create another scare. And a very crude, foolish attempt it is, if the Bell was really behind it—so crude and so foolish that it seems almost impossible to believe that the Bell people had anything to do with it, for usually there is at least some reasonableness and adroitness to the matter circulated by the Bell press workers. If it transpires that it was an output of the Bell literary bureau, there ought to be a job for a new director, one who would have sense enough to know that a capitalization of $700,000,000 for the telephone factories of the United States would be about as reasonable as the incorporation of a Cobweb Trust for the Quick Aging of New Wine Bottles.

Mr. W. J. Hilands, whoever he may be, wants to be careful, or he will find himself in the clutches of the Keepers of the Foolish Minded.



QUERIES

Questions on any subject relating to telephony will be answered on this page.



FARMERS' LINE.—(469.)

We are building a new farmers' line and expect to place about 15 subscribers upon it at average intervals of about one mile. Would you advise the use of two wires instead of one and the ground? Is there any lock-out device on the market that will do for as many stations as this number? What should the resistance of the bells be, and can we use brackets instead of cross arms? G. K. T.

In reply to the first part of your query: The day of grounded circuits is fast disappearing and although there still remain a few, yet in time it will be necessary to make them metallic. This will be due to the rapid growth of trolley roads, which cause the potential of the ground to change at various points. Quite frequently the earth offers a high resistance, and therefore a grounded telephone line, if in the vicinity, offers a lower resistance and part of the current will flow over it, making the line noisy. This is particularly noticeable when a car is near. Under these conditions a line often becomes inoperative, and consequently a lot of time is lost, whereas if the circuit were metallic this difficulty would be obviated. Several lock-out devices have been placed on the market, but for such a number of stations they are complicated and would require an expert to clear trouble on them. Ringers should have a resistance of 2,500 ohms to insure good operation. Brackets might be used if no more lines are contemplated in the future, but if there is a remote possibility of running additional ones, it would be the best policy to put up cross arms in the first place and save the cost later on. The size of the arms would depend upon future business.

MANUFACTURE OF DRY CELLS.—(470.)

Please describe the process of making a good dry battery cell, giving the name and proportion of chemicals used. In soldering the zinc can, should the soldered parts be protected from the action of the electrolyte with insulating wax? U. S. R.

As dry batteries are at present very inexpensive, we believe your best way would be to purchase in the open market such batteries as you desire, without attempting to construct them yourself. It is a saving of both expense and trouble. Most dry batteries are of the so-called sal ammoniac type; the positive element is the carbon and the negative element the zinc. The electrolyte is a pasty composition containing sal ammoniac. This is usually made by causing sawdust, gelatine, cellulose, or some other similar substance, to absorb the solution of sal ammoniac. The pasty mixture is then packed around the elements, and the whole placed in a suitable receptacle. Sometimes the zinc forms a can, and thus serves a double purpose of electrode and receptacle. In other instances a paste board, paper or box of other material is employed. The various mixtures used are usually kept secret, and are the result of prolonged experience.

IN THE OPERATING FIELD.

THE DEVELOPMENT OF LONG-DISTANCE LINES IN WESTERN PENNSYLVANIA.

THE completion of the cross-country telephone line in Western Pennsylvania, which the Pittsburg & Allegheny Company built to reach the National Telephone Company of Wheeling, marks one of the greatest improvements in long-distance Independent lines.

Through this line the Pittsburg & Allegheny will reach not only Wheeling and its immediate vicinity by an air-line route, five miles shorter than the Baltimore & Ohio Railroad, but will connect with Independent lines throughout southeastern Ohio and West Virginia. With the links that are rapidly being brought together in Ohio and Indiana it will serve as part of a through line from Pittsburg to Columbus, Cincinnati, Louisville, Indianapolis, Chicago, St. Louis and Kansas City and all the intervening towns.

It is announced that the Pittsburg-Butler line will be completed the last of this month. This will connect with the People's Telephone Company, covering Butler County, and will serve as an additional route to Northwestern Pennsylvania and Western New York. This territory is already reached by lines through New Castle, but the new route will give service through a section which has not been tapped by the Pittsburg & Allegheny heretofore.

The P. & A. Company's service has been greatly developed this summer, four new exchanges having been opened. These were at Crafton, Hazlewood, McKeesport and Duquesne, and they have added 3,000 subscribers to the list. The company now has over 15,000 telephones in service in Allegheny County. Still another exchange is to be opened shortly on Mt. Washington. This will have at the start upward of 500 telephones in service.

QUEEN CITY AGAIN TRIES TO ENTER CINCINNATI.

ARGUMENT was begun recently in the matter of the Queen City Telephone Company against the City of Cincinnati, O. The case had its origin before Judge Nippert in Probate Court, on an application by the Queen City Company, one of the Independent concerns, seeking entrance to the city, for definition of manner and mode in which it could use the streets and alleys. Judge Nippert recognized the claim of existing franchise, and defined the manner and mode of use of streets. Judge Littleford, of the Common Pleas Court, reversed Judge Nippert's finding, and the matter was carried to the Circuit Court. Powel Crosley and Provence Pogue appeared to assist C. Bentley Matthews, attorney for the Queen City Company. The two first-named are counsel for other Independent companies, the Interstate and the Fitzsimmons. City Solicitor Hunt was reinforced by Judges Peck and Outcalt, and Mr. Warrington, counsel for the City and Suburban. The full Circuit Court, Judges Giffen, Swing and Jelke, heard the argument.

ACROSS THE BORDER.

THE Privy Council at Toronto, Ont., has given judgment in the case of the City of Toronto vs. the Bell Telephone Company. It was decided that the company has the right to erect poles and to lay conduits without the consent of the municipality. The telephone company got a charter from the Dominion Government, and in the Quebec case of Regina vs. Mohr the question was raised whether the company had the power to operate in the provinces without provincial consent. The company then applied to and obtained from the Ontario Legislature another charter, in which was inserted a clause which the Dominion charter did not contain, that the company could not operate on any street without consent of the municipality. The city of Toronto tried to hold the company to this provision and litigation ensued. Justice Street gave judgment in favor of the city, but this was reversed by the Court of Appeals. The city appealed and the Privy Council has dismissed the appeal, giving judgment for the company.

INTERSTATE EXTENDING ITS LONG-DISTANCE LINES.

THE Interstate Telephone Company is constructing a new copper circuit from Sterling, Ill., to Rock Island. The work of setting the poles was completed last week, and a force of linemen at once began the work of putting up the wire. It will probably require six weeks to accomplish this work. When this line is completed the Interstate will have a direct toll line from Sterling to Rock Island. The cost of this improvement will be close to $12,000.

The company will also string a new copper circuit from Sterling to Dixon. When this work is completed the Interstate will have three toll lines running to Dixon from Sterling.

THE WINONA COMPANY PROSPERS.

THE Winona Telephone Company has grown in a remarkable way under its new management. The company owns the exchanges at Winamac, Knox and Keewana, Ind. New exchanges have also recently been put in at Hamlet and Grass Creek, and in every direction party lines have been extended over the country. When the new company took hold there were less than 350 telephones on the Winamac system. Now there are 700. On the Keewana system there were but 23 paying telephones, while now there are 125. The Knox exchange has also grown in like manner. Messrs. Samuel Tomlinson and A. B. Diggs have completely rebuilt the system, until they now have one of the most complete, up-to-date and best-arranged telephone plants in the State.

DUMMY TELEPHONE EXCHANGE.

A SWINDLING scheme on a large scale has been unearthed in New York through the fleecing of Herman Mayer, who reported to the police. Herman met a man named Henry Meyer, who unfolded to him a time-worn scheme of beating the pool rooms through a "leak" in the Western Union office and took him to a building to meet a man who was the "leak." Here Herman found a big room with a number of men busy at telephones. It was an exchange, he was told, whence the results of the races received from the telegraph company would be sent out to pool rooms. Henry introduced Herman to a "leak" and the "leak" said he could hold back the result of the race for seven minutes, but only one race a day. Later in the day Herman received a tip through the "leak" that a certain horse had won a race and he was hustled by Henry up to a room fitted up as a pool room and furnished in green with oak wood-work. Herman was so impressed that he bet $50 on a horse he didn't know. Ten minutes later he was told that he had won $90 on a steeple-chase at Gravesend. He was so delighted that he gave Henry half of the winnings and made an appointment to meet him on Saturday. On Saturday Herman drew $2,400 out of the bank to bet on a race with the expectation of winning in the same way that he

Digitized by Google

had done previously. He bet his money, and of course failed to win. He got the police interested in the affair, and they investigated the telephone exchange that he had first visited. There were thirty-six telephones on the walls with fake switchboards. The telephone wires ran into the walls only. Only two of the telephones had a transmitting diaphragm and a few were still in their wrappings. Henry Meyer was arrested, and so was the man who acted as a "leak."

INDEPENDENT COMPANIES JOIN EASTERN TRAFFIC ASSOCIATION.

AT a recent meeting of Independent companies held at Cumberland, Md., it was unanimously voted to join the Eastern Traffic Association of Independent Telephone Companies. Represented at the Cumberland meeting, besides all the principal Independent lines of Maryland and West Virginia, including the Maryland Telephone Company, of Baltimore, and the Consolidated Company, of Fairmont, W. Va., were the leading anti-Bell companies in Western Pennsylvania, including the Pittsburg & Allegheny Telephone Company, the Pittsburg-Johnstown Long Distance, the Johnstown Telephone Company, the Tri-State Telephone Company, of Uniontown, Connellsville, and the coke region generally; the Somerset County Telephone Company, the United Telephone & Telegraph Company, which operates between Altoona and Philadelphia; the Huntingdon & Clearfield Telephone Company, which has lines in the north of Cambria County, and a number of others.

As a result of the new move the long-distance service of all the lines concerned will be controlled for an interchange of business; a uniform rate of charges will be established, and a uniform standardization of the system perfected. All moneys for long-distance service beyond the territory of the respective lines will be forwarded to the proper exchanging companies, and in many ways an improved and enlarged service will be made possible.

TELEPHONES IN FRANKLIN COUNTY, IOWA.

THERE are now operating in Franklin County 19 different telephone lines, with mileage in this county of from one to one hundred and forty-eight miles. The total assessable mileage in the county is 650 miles and the valuation placed thereon by the executive council is $23,483. This valuation brings to the county for the ensuing year at an estimated rate of 4 per cent. a total tax of $1,039. From rural telephones alone the county derives over one thousand dollars each year.

SOME INDEPENDENT FINANCIAL REPORTS

BELOW will be found reports from two groups of Independent companies which make the Bell literature on the "Danger of Independent telephone securities" seem particularly silly. The statements shown are from companies which operate in the strongholds of the Bell, and which have flourished almost beyond expectation. In the case of the Home Telephone Company, of Los Angeles, the figures indicate a development far beyond any ever dreamed of by the Bell and furnish food for careful thought by all investors. The Sunset (Bell) Telephone Company had operated for years in this territory with but varying success, and yet in one year's time the Home Telephone Company installed more telephones than the Bell had been able to install in twenty years.

The reports from the subsidiary companies of the Federal Company of Ohio, furnish another proof of the financial success which can be secured by capable management. The securities of these companies suffered in the collapse of the Everett-Moore syndicate. The Bell press bureau has for years paraded these properties as "terrible examples" in the newspapers that it has been possible to subsidize. Yet to-day the properties show recuperate powers far in excess of the Bell proteges which went down and out in the past, and almost beyond the expectation of their owners. During the past years a tremendous amount of construction has been going on among the various companies in this group, and it is only a matter of a short while when the net earnings will be far in excess of the present showings.

First Annual Report of Home Telephone Co., of Los Angeles.

Los Angeles, Cal., November 1, 1904.

To the Stockholders of the Home Telephone and Telegraph Company of Los Angeles, California:

Herewith find a statement by quarters of the earnings of your Company for its first year's business, commencing October 1, 1903, and ending September 30, 1904.

It has not been possible to give service to all who have desired to use the system, a long waiting list resulting.

Extensions are now so far advanced that residents of the Southwest and in the Business Section of the city can have immediate service; the Vernon district, Boyle Heights, East Los Angeles, Highland Park, Garvanza and Prospect Park, within thirty days.

The earnings of your Company hereafter, because of the increased number of telephones which will soon be installed, should be better than in the excellent showing made herewith.

	First Quarter ending Dec. 31, 1903	Second Quarter ending April 1, 1904	Third Quarter ending July 1, 1904	Fourth Quarter ending October 1, 1904
Quarterly Earnings	$67.633.71	$79,698.59	$86,944.39	$89,867.22
Operating Expenses, Taxes, Insurance, Maintenance and Interest on Bonds	45,274.10	47,881.08	50,469.46	51,946.00
Net earnings for quarter		31,817.51	36,474.93	37,921.22
Surplus from last quarter		5,029.61	17,867.12	34,262.05
Available for dividends, improvements or surplus	22,359.61	36,847.12	54,342.05	72,183.27
Dividends paid	17,330.00	18,980.00	20,080.00	21,580.00
To surplus	$5,029.61	$17,867.12	$34,262.05	$50,603.27

NEW STROMBERG-CARLSON DEVICES.

IN Bulletin No. 12 the Stromberg-Carlson Telephone Mfg. Co. are illustrating some new and interesting telephone appliances.

Figure 1 is a two-way improved ringing and listening key. The illustration shows that there are three sets of springs, which may be actuated by *a* in the center of key in the usual manner. The outer set of springs is the listening key, and when the key is thrown clear over it is locked and the operating set cut into service. The inner set of springs are arranged for ringing in such a manner that the movement of the cam closes the ringing circuit only for such a period of time as the operator desires the ringing current to remain on the line. Upon releasing the cam it automatically returns to normal position, cutting the ringing key off. The third set of springs may be actuated by means of the button shown at the left hand of the cam, under which this set may be used either for ringing, or for an order wire, or for any other work which may be desired.

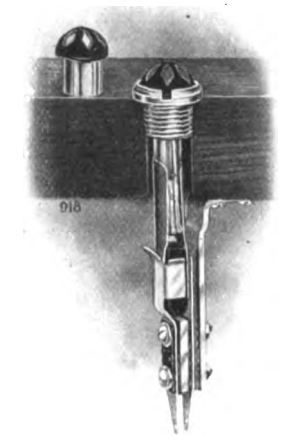

Fig. 2.—Stromberg-Carlson Lamp Socket and Cap.

Figure 2 is an improved form of lamp jack. As is shown in the illustration, the jack itself is secured to the under side of the cord sheath, and consists of a pair of parallel brass clips into which the lamp may be inserted, which form the terminals, connecting the battery circuit to the ends of the lamp filament. The opal lamp glass is inserted in brass ring, which is threaded and may be screwed into the top of the sheath. The opal is covered with a metallic cord, which is perforated to allow the illumination of the lamp to be perceived, and at the same time prevents the opal from being broken by falling plugs.

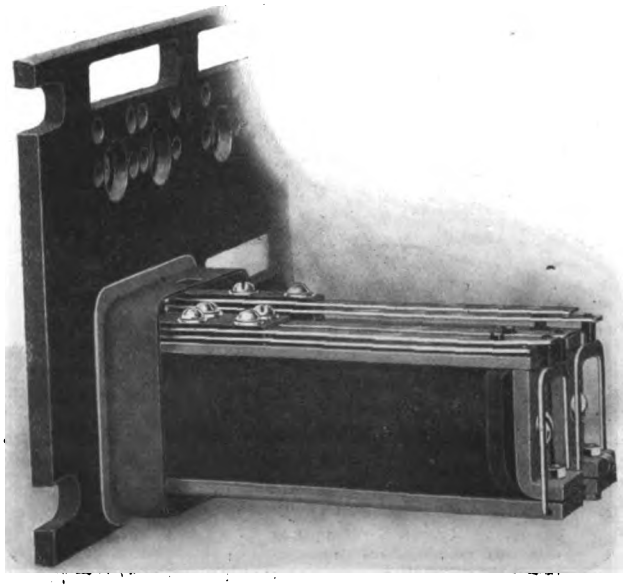

Fig. 4.—Stromberg-Carlson Double Relays Mounted.

Figure 3 is an illustration of a single relay. The coil is supported in a substantial iron frame, which forms the magnetic circuit. The armature is knife-edged, pivoted upon the front plate of the relay; and when attracted operates the contact springs, which are placed upon the top of the iron frame. The springs are platinum pointed. and sufficiently stiff to insure positive and reliable contact, having a threaded stud and pair of nuts projecting from the front end of the relay, whereby it may be secured to the entire framework.

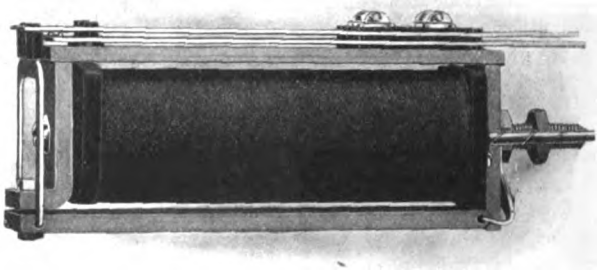

Fig. 3.—Stromberg-Carlson Single Relay.

Figure 4 shows a double relay, which to all intents and purposes is a pair of relays, similar to that shown in Figure 3, that are mounted upon a single escutcheon plate, so that they may be secured in pairs to the framework of the switchboard.

By this device each pair of relays may be used to form party-line cut-off relays or a single line.

AMERICAN ELECTRIC TELEPHONE CO., Chicago, Ill., has just issued a new catalogue in bulletin form, i. e., each subject is treated separately and bound separately, so that if an inquiry is received for any special apparatus just that bulletin which pertains to that apparatus is sent, and the inquirer is not loaded up with a complete catalogue of everything the company manufactures, although if one desires the complete catalogue the different bulletins can be bound together with a suitable cover. It is its endeavor to find out just what the inquirer wants and send the literature which bears on this subject alone.

THE T. AND A. SELECTIVE CALL CO., Geneseo, Ill., seems to have met the requirements of many rural lines from the number of orders for its selective signaling device. A successful piece of apparatus is nearly always a simple one, and this is true of this device. A relay at the central office is so arranged as to only close the circuit of a line to the drop when it is so desired, not responding to signals from one subscriber to another on the same line. The circuits over which it will operate may be grounded, metallic, or divided circuit metallic; and in each case

FOR SALE

Advertisements under this head, $1.00 for 25 words or less for each insertion. Prepaid.

FOR SALE.—I have a telephone proposition which will interest any one of means who cares to investigate. This property is in fine condition; located in excellent field and paying. Write me at once. Box 270, care of AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 270

EXCEPTIONAL offer—I have a three-fourths interest in a telephone stock company owning four good exchanges and 1,000 miles of toll and farmer lines. About 1,000 telephones in operation and sufficient territory for that many more. Stock outstanding amounts to $50,000. Has earned over 30 per cent. in past two years. No competition; $25,000 cash and balance long time; low rate. Address Box 291, AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 291

FOR SALE—500 Tornquist double-pole porcelain base, king of protectors, 50c each; 300 single-pole, 25c each. Address J. S. Maurer, 804 Monadnock Building, Chicago, Ill.

WANTED

Advertisements under this head, 25 cents for 25 words or less for each insertion. Prepaid.

WANTED—A good man for instrument work, who can also run wiring for electric lights. Address Box 287, care of THE AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 287

WANTED—First-class wire chief; magneto and central energy. Must fully understand installing multiple switchboards, etc. Address Box 288, care of THE AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 288

WANTED—Position with telephone company. I am an expert lineman and repair man; three years' experience; best of references furnished. Address P. O. Box 591, Toledo, Tama County, Iowa. 278

WANTED—To meet an investor with capital with a view to developing an automatic telephone which can be made at one-third cost of present automatic systems, also other telephonic devices. Exceptional opportunity. No agents or promoters need apply. Apply Box 272, care AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 272

WANTED—Position as superintendent of a large exchange or manager of a plant, 1,000 telephones or less. Have had ten years' experience in all branches of the business. At present am superintendent of an exchange in a city of 175,000 population. Open January 1st to any company that wants a hustler. Address Box 286, AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 286

WANTED—Position as manager with a first-class company looking for a hustler. Experienced particularly in toll and long distance work, including clearing house methods, and line construction. Familiar with every detail of telephone work. Executive ability; excellent references. Address Box 285, care THE AMERICAN TELEPHONE JOURNAL, New York. 285

POSITION wanted by expert telephonist. Twelve years' experience from bottom up. Address Box 295, AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 295

WANTED—Telephone salesman who has had experience in handling intercommunicating and private branch exchange apparatus. Address Box 296, AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 296

the operation is the same: to call central, push one button; to call subscriber, push the other. You are invited to write for particulars and descriptive matter.

A NEW HOOK SWITCH.

AMONG the many original features brought out in the new telephone apparatus of The Dean Electric Company, Elyria, Ohio, is a removable lever type hook switch.

In the regular construction the hook lever projects from the side of the telephone, taking up extra space in shipping and in the store room, also requiring the instrument to be handled with extreme care to prevent the lever and its connected mechanism from being damaged. The new Dean hook switch is provided with a removable lever which need only be inserted in position after the telephone is mounted on the wall. When the lever is once in place it is securely locked by a spring catch, and can then only be removed by opening the lid of the telephone box as the release is located on the body of the switch.

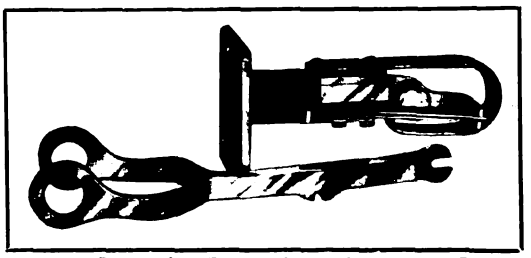

Fig. 1. Illustrating Removable Hook Lever of Dean Electric Co.'s New Type Hook Switch.

The removing and replacing of the lever does not require tools, neither does it disturb the switch mechanism, which is actuated by a stub lever. The latter serves as a lock to hold the hook lever in place and partakes of its motions when the hook is operated.

The Dean hook switch is self-contained in every sense of the word and is complete in itself, even to the escutcheon, so that no dependence need be placed on the telephone cabinet for operation or for holding the parts in their relative positions. It is fastened to the telephone by four screws passing through the escutcheon frame, an opening 15/16-inch in diameter being provided for inserting the body of the switch.

The contact springs are mounted on a small metal block which forms a unit. The various combinations of springs necessary to adapt the hook switch to different circuits being like mounted and interchangeable with the remainder of the mechanism. The accompanying illustrations show a two-contact spring combination for use on a central battery telephone. The contact springs are made from the best grade of spring German silver, tipped with pure platinum points and thoroughly insulated with hard rubber.

The hook switch frame and lever are thoroughly insulated from the parts entering the circuit, so that it is impossible to obtain annoying or dangerous shocks by personal contact with the exposed metal.

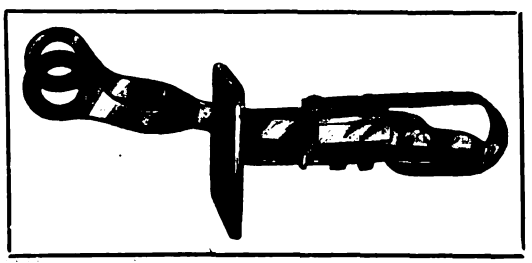

Fig. 2. The Dean Electric Co.'s Hook Switch Assembled.

The actuating or main spring is special German silver made heavy and long and with its tension applied near the fulcrum of the lever, thereby giving a light and positive action to the hook.

The entire hook is made up without castings or other breakable parts, and is finished in heavy nickel plate. all parts subjected to corrosion being copper plated under the nickel.

PERCY R. STEEL, 17 North Sixth street, Philadelphia, reports a large volume of business for his new type of distributing or bridle ring. This ring was described at length in a recent issue. Orders have been received from some of the largest companies in the country, and an extraordinary number of inquiries have come to hand relative to this important adjunct to the line construction of a system. This type of ring is made up in different finishes, as follows: Glass enamel, which offers an exceptionally high resistance; galvanized, and japanned. Besides this article, the manufacturer has a number of different hardware specialties for sale which are in daily use, such as iron pins, pole steps, lag screws, pipe clamps, etc. Information and prices of these articles will be gladly mailed upon request.

W. S. SEAMAN AND COMPANY, 216 E. Water street, Milwaukee, Wis., has had an unprecedented sale for its booths. Evidently the Independent operators throughout the country appreciate the dividend-earning capacity of booths, especially when they are built upon the most modern lines to secure secrecy and to exclude sound. For public pay stations a booth is as much a necessity as good transmitters and receivers, because people often wish to carry on a conversation that is private, and consequently when a booth is installed, as in a railroad station or general store, it will draw returns which will make it pay for itself in a short while. This company is a pioneer in the manufacture of booths and is able to turn out an article second to none. All communications will be cheerfully answered, and prices and other information furnished on application.

THE MORRIS ELECTRIC CO., Wilmington, Del., which manufactures hard fiber specialties for the electrical trade, is working over time to supply the demand for the fiber cleats. This little novelty is evidently filling a long-felt want, as orders are being received from every part of the country and range in size from lots of one thousand to half a million. When the quality of the article is considered, and one might say its almost universal need, it is not hard to understand this demand. It is as much ahead of the old-time wooden or porcelain cleat as a solid back is in advance of the early type of magneto transmitter. Being practically indestructible. it can be used indefinitely, and will always give the same solid grip which insures the neat appearance ot inside wiring which characterizes its use. Although the company is receiving orders every mail which keeps its factory working to its utmost capacity, it will be only too pleased to furnish samples and prices to all parties interested.

THE S. H. COUCH CO., 162 Pearl street, Boston, Mass., is meeting with remarkable success with its No. 10 private line and central station telephone. This instrument offers one of the most compact and practical arrangements of interior telephone apparatus put on the market. To exchange operators and managers the instrument should prove a large source of revenue, as there are many places where an intercommunicating telephone system can be used to advantage, as in stores, mills and private houses. On the farm, between outbuildings and the house it is very convenient, saving many steps which would otherwise be necessary, and since time saved is money earned, the use of this instrument should be a dividend

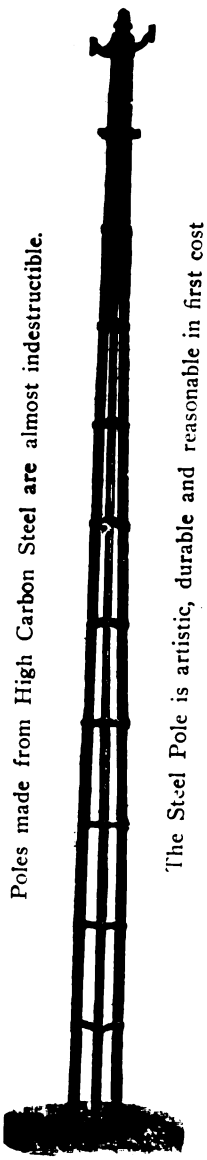
The Open-Wireless Telephone Plant

is an all-cable plant; that is, it has no open wire (bare wire) or cross arms, and when supported on steel poles

DEPRECIATION IS ALMOST ELIMINATED; MAINTENANCE REDUCED TO A MINIMUM



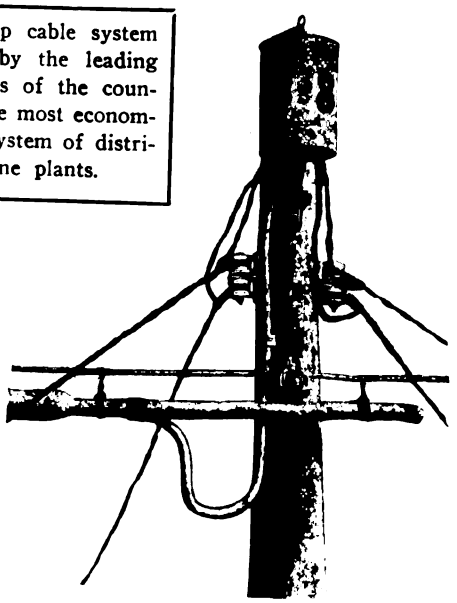
POLE OF THE FUTURE

Poles made from High Carbon Steel are almost indestructible.

The Steel Pole is artistic, durable and reasonable in first cost.

No poles to rot.
No cross arms to rot.
No glass insulators to break.
No crossed wires to interfere with service.
Trees do not interfere.
Sleet storms lose their terror.
No unsightly cross arms and wires on the streets.
No bare wires to break and fall on electric light wire and kill someone passing by.

The multiple tap cable system is acknowledged by the leading telephone engineers of the country to be by far the most economical and durable system of distribution for telephone plants.



THE SYSTEM OF THE FUTURE

The undersigned is a pioneer in multiple cable distribution and makes a specialty of

Planning Cable Layouts
Multiple Cable Distribution
Equipping for Party Lines
Rate Raising, Etc., Etc.
Plans, Specifications and Supervision of Installation of Complete Telephone Plants

WILL GUARANTEE TO INCREASE THE DIVIDENDS IN 99 TELEPHONE PLANTS OUT OF EVERY 100

Engineering, constructing and putting plants on a dividend-paying basis a specialty.

There are many serious mistakes made in the selection of apparatus, construction and maintenance of telephone plants due to lack of experience.

There are many leak holes in a telephone plant unless properly watched.

With proper co-operation on part of owners of telephone plants I will guarantee to make any Telephone Plant pay dividends or increase your present earnings. Can refer you to a number of telephone plants where I have saved thousands of dollars in first cost of the plant, increased the earnings, improved the service, decreased the operating expenses by installing proper apparatus in the proper way and properly organizing the working force. Can furnish expert engineer, wire chief, auditor, solicitor, chief operator, each a specialist in his line.

maker. Write for bulletins and prices and get acquainted with it.

THE TELEPHONE PRINTING CO., of Defiance, Ohio, has developed the accounting and recording systems for telephone companies to the highest point of efficiency. Since the financial returns are what keeps a company in operation, it is evident that the best methods of business are necessary. This company meets these demands with its line of blanks, forms and books for every conceivable use, among which may be noted the following: toll tickets, trouble tickets, exchange directories, toll station journals and ledgers, toll receipts, lease and rental records, etc. A card index system specially designed enables the simplest record of a line to be kept and makes possible a system which is always up to date and full of just the information one wants. Samples and forms will be mailed upon application.

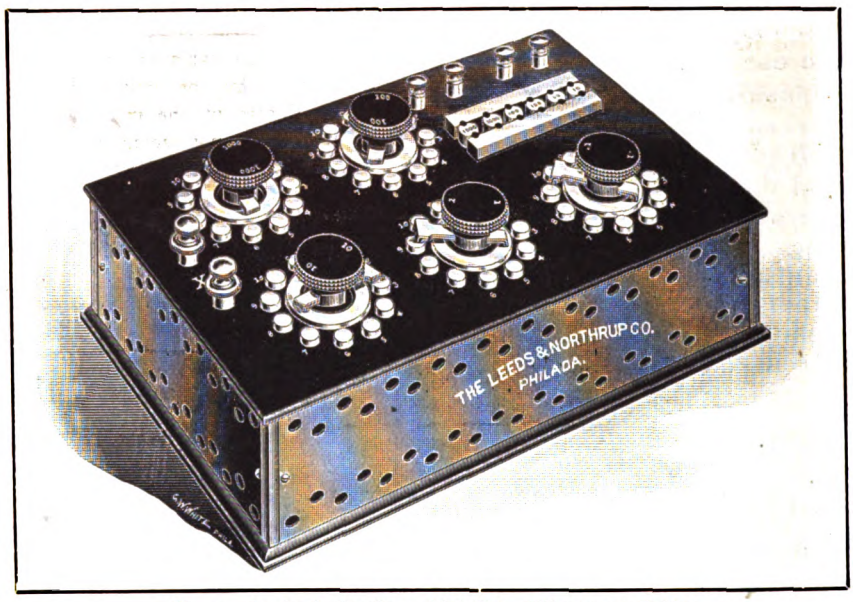

Fig. 1.—Leeds & Northrup Dial Type Wheatstone Bridge.

LEEDS AND NORTHRUP WIN GRAND PRIZE.

AS any industry develops it necessitates a corresponding evolution of all kindred branches of manufacture to which it may be more or less directly related; and so the evolution of the telephone has caused a corresponding development in the perfection and manufacture of electric instruments.

In this development the LEEDS & NORTHRUP COMPANY, of Philadelphia, have now one of the most advanced places among American manufacturers of electrical apparatus. At the Louisiana Purchase Exposition this company presented one of the most extensive exhibits of the highest grades of electrical testing apparatus, for which they have been awarded the Grand Prize, which is the highest encomium within the power of the Exhibition Company to bestow. To describe the exhibit, the Leeds & Northrup Company have issued an exceedingly attractive and comprehensive catalogue, which illustrates all of the various instruments of their manufacture, and accompanied by a description in two-color work, whereby the salient features of each instrument are placed before the reader in such a manner as to bring the noteworthy points of excellence particularly into relief.

The first few pages are devoted to a description of the various forms of Wheatstone bridges, rheostats and other apparatus for the measurement of resistances, the special features being the designing of the resistance coils upon an improved metallic spool, the superior arrangement of the ratio coils, and the design of the plug having no sharp corners, with heads so arranged that the insulating portion cannot be removed; the method of constructing the plugs and their sockets so that good contact may be always secured. Then comes a description of the various forms of potentiometers, including many designs of the slide wire bridges and other forms of apparatus for measuring low resistances. The so-called dial pattern occupies a prominent place. It is illustrated in Fig. 1. While this form of the Wheatstone bridge is somewhat more expensive to construct than the ordinary type, it is well worth the additional cost, because it can be manipulated so much more readily than the plug type, and from the fact that there are no loose parts that can under any circumstances be loosened, and furthermore there is little possibility of making an error in reading the coils of the rheostat, which are included when a measurement is made.

Fig. 2.—Leeds & Northrup Portable D'Arsonval Galvanometer.

Two unique and particularly desirable forms of the D'Arsonval galvanometer are shown in the catalogue, one a hollow tube which may be readily clamped upon any supporting partition, and that carries a scale and telescope having universal adjustment, to permit of easy manipulation; another, which is illustrated in Fig. 2, is mounted in a box, with a rubber top and two binding posts. The coil is circular in form, turns over an iron core, and is mounted upon jewels. It is very sensitive for a galvanometer of this type, is thoroughly well made and the pivoted system has exceedingly small friction. The current due to one volt through 1 megohm will cause

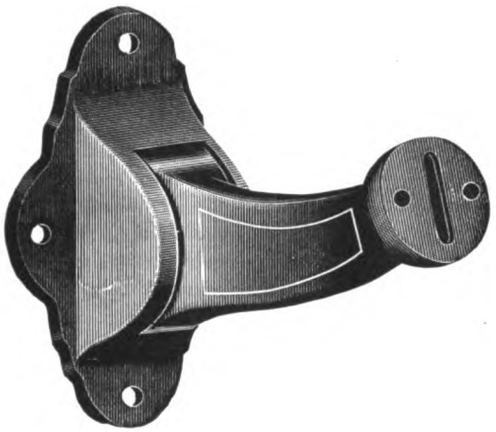
THE NEW

Baird Telephone Arm



Invisible Joint. Constant Friction. Nothing to get out of order. Nothing to adjust. No handling required after it has been enameled and striped. This insures a perfect finish. A 1905 telephone set without it would be a back number. When buying new equipment insist upon this arm. Made in different length arms and different style bases. Costs no more than present type of arm. Illustrated circular and prices upon application.

the pointer to move about 1 mm. over the scale. The pointer can be adjusted to zero from the outside of the case and the coil is so well balanced that the galvanometer can be used in an inclined position. This instrument will be found very useful in all places where a sensitive, portable detector galvanometer is required. The scale over which the pointer moves is calibrated for 10 divisions each side of the zero, so that up to this limit the galvanometer will serve as a measuring instrument when its constant has once been determined.

Various forms of self-induction apparatus and condensers are illustrated, and finally the catalogue closes with an extended account of the Rosa curve tracer, an instrument that is of inestimable importance to those dealing with alternating current appa-

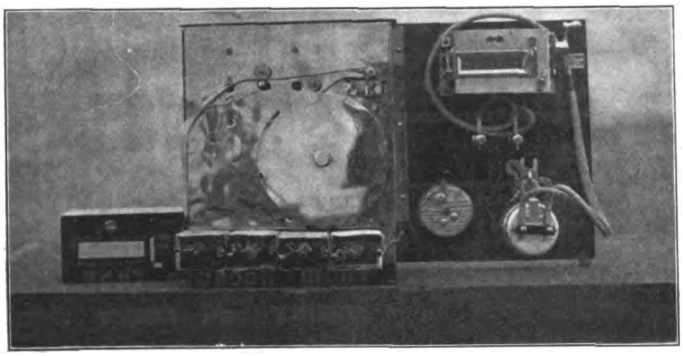

Fig. 1. Register and Recorder of Demonstration Set Used by the Measured Service Co.

ratus. Illustrations are given showing the working of the various methods of electrical measurements to which the Rosa curve tracer is especially applicable.

There is not a telephone company of any importance in this country to which the Leeds & Northrup Company's apparatus is not of interest. Quick and accurate service on a small margin of profit is the keynote of the Independent telephone business. Good measuring, testing and fault-locating instruments go a long way towards the accomplishment of quick and accurate service. Every telephone company therefore should have a copy of this new Leeds & Northrup catalogue, which will be gladly sent to anyone interested.

NEW MEASURED SERVICE METER.

A SHORT time ago in our columns we described a measured service meter, which has recently been placed on the market by the Measured Service Company; and now this corporation has produced a modification of their coin box, particularly adapted to use in combination with a desk set. The desk set meter consists of a handsome nickel-plated base, which forms the foundation, which is about one-quarter of an inch larger than the standard wall meter. Either side of the base is supplied with a screw hole, so that the meter may be quickly and easily attached to any part of the desk or other piece of furniture without marring it in any way. The special base is so constructed that three wires from the meter lead out through a single insulated outlet at the top. This makes the wire connection very simple and very neat, and presents an even more attractive appearance than the wall meter. This design has been termed model B, the mechanism being identical with the wall device, which is termed model A. With a view toward placing its apparatus before all telephone managers and operators throughout the country, this company devised a sample set which could be used to demonstrate the simplicity of its meter system. These sets were placed in the hands of efficient men, who have been visiting various exchanges, describing to the managers many salient points of measured service.

The apparatus is illustrated in Figs. 1 and 2. Fig. 1 shows the meter mounted on the upper right hand corner and the statement-taking device on the left. The batteries, receiver and switch complete the device. The object of the receiver is to enable the signal to be heard, which is sent in when a call is recorded. The switch controls the circuit to the recording instrument, which consists of a drum holding a roll of paper tape. This tape is drawn by means of clockwork through a printing machine which has a wheel controlled by a magnet, so arranged that when the circuit is closed the printing wheel is drawn into contact with the paper and, according to the length of time, so the wheel prints either dashes or dots. These dashes and dots represent numbers or combinations of numbers.

When a statement is being taken, the lever to the right of the meter is pulled down. This causes a contact point to travel along a grooved rod, shown in Fig. 2.

When the lever is released, it moves back by clockwork and causes the contact point to travel back; as it does so it makes and breaks contacts upon the registering wheels and thus sends in impulses of various durations, which actuate the clockwork and printing mechanism of the statement-taking machine. Fig. 2 illustrates the mechanism of the register and recorder.

BAIRD MANUFACTURING CO., 4 Michigan street, Chicago, Ill., has just contracted with several of the large telephone manufacturing companies for their entire output of telephone arms. The Baird invisible joint, constant friction arm has taken the eye of telephone men wherever it has been shown, and those manufacturers who have not seen the arm would do well to get in communication with the company about them. It is the only arm on the market which is completely enameled and striped after it is assembled. The friction in the arm is permanent as soon as the arm is assembled. One of these arms was recently attached to a machine in their factory and given approximately one million motions to ascertain how lasting was the friction. There was apparently no change in the friction after this experiment. It is in the market to supply these arms in any quantity at very short notice. Special prices are made where it supplies a company's entire output of transmitter arms. Prices and more detailed information will be gladly furnished.

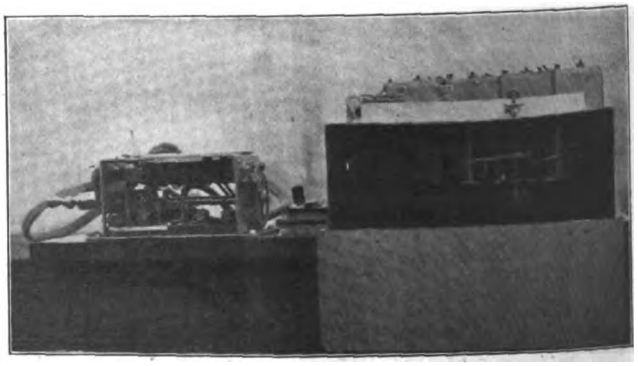

Fig. 2. The Mechanical Arrangement of Measured Service Co.'s Demonstration Set.

FRANK B. COOK, 240 West Lake street, Chicago, Ill., is conducting experiments at Lewis Institute on new protective devices, which, he says, will practically revolutionize the present system, as they are along entirely new and different lines.

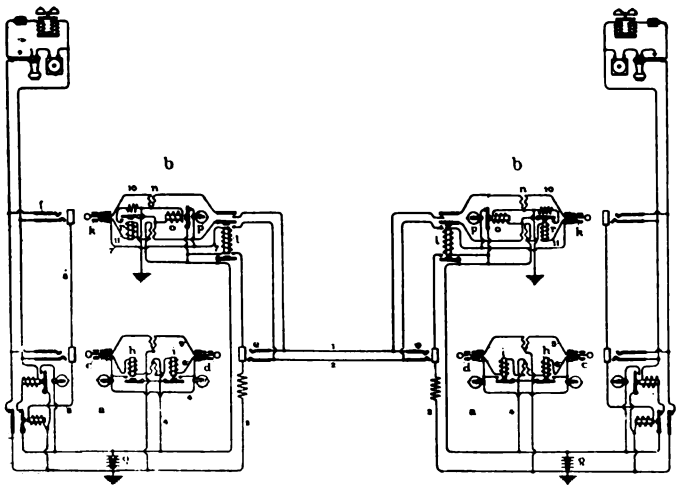
TELEPHONE PATENTS

TRUNK LINE CIRCUIT.

F. R. McBerty, of Evanston, Ill., patents (No. 772,898) an improved trunk line circuit and assigns to the Western Electric Company. This invention relates to trunk line circuits so arranged as to be used for either incoming or outgoing work from either exchange. The circuit arrangement is shown in the accompanying illustration and the operation is as follows: Line spring jacks *e* are multipled in the subscribers' sections, the test thimbles forming branches of conductor *3* which is designed to form a part of a local circuit *3 4* with the flexible conductor terminating in a corresponding contact of the plug *d*. The plug circuit *5 6* of the plugs *c* and *d* is connected to the central battery *g* in the usual manner. Besides the trunk line jacks branches are taken to the terminal plug *k* of the trunk line at the incoming section. These branches are controlled by an electromagnetic switch *l*, the actuating magnet being connected in conductor *7* terminating in the local contact of the plug *k*, and is thus brought into the local circuits *7 8* with a corresponding wire *8* of a sub-



scriber's line when the trunk line is united therewith. The extensions *1* and *2* of the trunk line after traversing the separable contacts of relay *1* are united through the windings of a repeating coil *n* and the magnet relay *o*. This is of sufficiently high resistance to prevent the actuation of supervisory relays *h* or *i* by the current when plug circuit *5 6* is connected with the distant terminal of the trunk line. This relay controls the circuit through a clearing out signal *p* connected in the conductor *7* in parallel with magnet switch *1*. The other windings of the repeating coil *n* are in circuit *10 11* which is a continuation of trunk line *1 2*, including the source of current *g* and the magnet of relay *r* whose contacts control the shunt of relay *o*. When the trunk line is not in use, only the terminal spring jacks are connected with it. In using the trunk line, the order is given by the subscriber's operator in the usual way, and at the same time the calling subscriber is linked to the plug line and by the plugs *c* and *d* inserted in the jack of the calling subscriber and the outgoing jack *e* of the trunk line.

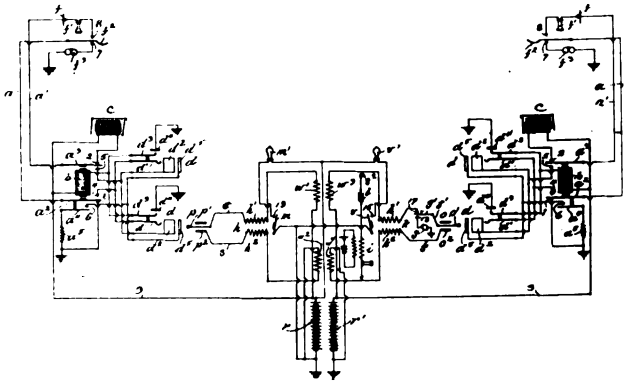
SWITCHING MECHANISM FOR INTERCOMMUNICATING TELEPHONES.

A. K. Andriano and H. Herbstritt, of San Francisco, Cal., patent (No. 771,114) an improved switchboard mechanism for intercommunicating telephones and assigned by mesne assignment to the Direct Line General Telephone Company, of San Francisco. This is a patent upon improved mechanism for switching particularly adapted to intercommunicating systems. The object is to enable one station to call and come at any other station without requiring the services of the central station operator. Each substation set is provided with a movable switch and contact points corresponding to each line. The switching mechanism operates electromagnetically and is located at some central point which corresponds to a switchboard and in this respect the invention belongs to the automatic class.

The invention is too complicated to be described in our brief abstract, and those interested are recommended to secure a copy of the patent.

IMPROVED COMMON BATTERY SWITCHBOARD CIRCUIT.

Kempster B. Miller, of Chicago, Ill., patents (774,770) an improved common battery switchboard circuit and assigns to the Kellogg Switchboard and Supply Co. The object of this patent is to provide an improved common battery switchboard circuit. It contains most of the features which are so familiar in the



Kellogg circuits. The circuit is diagrammatically shown in the accompanying illustration, the operation of which is as follows:

Assume the right hand and left hand subscribers to be represented by capitals *A* and *B*. If *A* removes his receiver he closes the circuit through the line lamp *a* and *a'*, completing circuit from battery *r* through conductor *3*, through line signal *c*, contacts *2* and a^2, conductor *a'*, conductor *a*, contacts a^2 and *1* to battery. The line signal *c* is actuated and the operator inserts the answering plug *p* into the answering jack *d*. The tip of the plug moves spring *d'*, carrying spring d^2 to contact d^4. Circuit of relay *b* is then closed from ground through battery *r*, conductor *3*, relay *b*, spring d^2, contact d^4 to gound. The armatures a^2 and a^3 are attracted, contacts one and two opened, deenergizing the line signal *c*, and the springs a^2 and a^3 engage contacts *4* and *5*, connecting the spring jack with the line. The plug also completes circuit from battery *r* through windings *w'* and w^2 of the repeating coil to the windings *h'* and h^2 of the supervisory relay *h*, through conductors *t* and *s* and the line conductors *a* and *a'*. As the windings *h'* and h^2 are differential the relay *h* is not excited and the lamp *m'* is not illumined, The operator tests and rings in the usual manner, as is easily traced over the circuit shown. When subscriber *A*, for example, restores his receiver the circuit of battery *r* is closed through windings *w'* and *h'*, strand *t*, tip of plug *p*, line spring *d*, contacts *4* a^2, conductor *a* to ground, while the other side of the line is open. The current traverses winding *h'*, while h^2 is de-energized; the supervisory relay then attracts armature *m* closing circuit through the supervisory lamp *m'*, notifying operator that subscriber has returned receiver.

THE WEEK'S MESSAGES

FINANCIAL.

WASHINGTON, D. C.—The National Telephone & Electric Company has been admitted to the State of Illinois with a capital of $100,000 to be employed in that State.

WEST STOCKBRIDGE, MASS.—The Mutual Telephone Company has voted to declare a dividend of 7 per cent. on its past six months' earnings.

BATTLE CREEK, MICH.—The Citizens' Telephone Co. has declared a semi-annual dividend of 4 per cent. The following officers were elected: E. B. Fisher, president, Grand Rapids; L. McCoy, vice-president, Battle Creek; C. F. Tart, secretary and general manager, Grand Rapids; L. W. Robinson, treasurer, Battle Creek.

COLUMBUS, OHIO.—The Citizens' Telephone Co. has decided to issue $200,000 of preferred stock. This amount was left unused of the original capital of $500,000. The money will be used in defraying the cost of construction of a new building and the proposed automatic switchboard.

INDEPENDENCE, OREGON.—The Independence Mutual Telephone Co. has increased its capital stock from $500 to $1,000.

McKINNEY, TEXAS.—The McKinney Telephone Company has increased its capital stock from $20,000 to $30,000.

FRANCHIISES.

DENVER, COL.—The El Paso Telephone Co., of Colorado City, will apply for a franchise in this city, and also El Paso, Teller, Fremont and Pueblo County.

ALTA, IA.—The Alta Telephone Company, of this city, has been granted a franchise for twenty years. The company is composed of David E. Hadden and G. Frank Tincknell, and is entirely owned by local capital.

SPRINGFIELD, MASS.—The Commercial Telephone Co. has applied to several towns in the State for permission to erect its poles preparatory to establishing service.

WESTBROOK, MINN.—The Southwestern Minnesota Telephone Co. seeks a franchise through here.

PROVIDENCE, R. I.—The Town Council of Narragansett has granted a franchise to the Providence Telephone Company.

ELECTIONS.

MOUNT MICA, ME.—The Mount Mica Telephone Company has elected the following officers: President, C. S. Childs; treasurer, Scott Briggs; clerk, Wm. Colby.

ROCKPORT, MISSOURI.—The Mutual Telephone Company has elected the following board of managers: Dr. A. McMichael, Dr. W. R. Strickland, Dr. J. H. Hedgpeth, H. F. Stapel and W. B. Christian.

CHATHAM, N. Y.—At the annual meeting of the Chatham Co-Operative Telephone Co. the following officers were elected: President, R. W. Seymour; vice-president, E. B. Gifford; secretary, F. B. Pratt; financial secretary, J. H. Page; treasurer, H. A. Branion; superintendent, P. G. Babcock.

KINDRED, N. D.—P. M. Andersgard has been elected president of the Neighbor State Telephone Company, and Sam Gilbertson, secretary.

PORTSMOUTH, O.—The Portsmouth Telephone Company has elected the following officers: H. S. Grimes, president; J. S. McKell, vice-president; E. E. Knox, secretary and general manager.

SUSQUEHANNA, PA.—The Susquehanna Telephone and Telegraph Co. at the annual meeting elected the following-named board of directors: C. E. Titsworth, M. H. Cisman, Frank Zeller, E. W. Jackson and M. J. Lannon.

FREDERICKSBURG, VA.—The Orange Telephone Co. declared a dividend on its stock, and elected the following officers at a recent meeting: G. S. Shackleford, president; Col. C. C. Taliaferro, vice-president; J. Crittendan, general manager.

COMBINATIONS.

NEWBURG, IA.—The Grinnell & Newburg Rural Telephone lines have been purchased by J. L. Burrough, who will continue to run the line.

WATERVILLE, KAS.—J. J. Groesbeck has sold two miles of a local telephone line to the Irving Telephone Company.

LONDON, KY.—John Woodward, of Barkerville, has leased the London Telephone Exchange for two years.

NEW COMPANY NOTES.

HUNTSVILLE, ALA.—Inter-County Telephone Company is being organized by a number of farmers in Madison and Morgan Counties.

BEARDEN, ARK.—The Bearden Telephone Company, of this city, has been incorporated with a capital stock of $2,000, of which $1,000 has been subscribed. Wm. M. Gatling, president; Jeff Gatling, secretary; Wm. Gatling, Jr., treasurer.

SYCAMORE, ILL.—The Selected Signal & Telephone Mfg. Co. has been incorporated with a capital stock of $100,000 by J. C. K. Joslin and others.

LAKETON, IND.—The Disko and Laketon Telephone Co. has been incorporated with a capital stock of $15,000. Directors: F. J. Zimmerman, E. L. Harmon and H. C. John.

SOLON, IA.—The Solon Telephone Co. has been incorporated with a capital stock of $900. President, J. F. Potter; vice-president, M. T. Loder; secretary, J. J. Fiala; treasurer, Geo. Ulch.

HALLOWELL, ME.—The Woodland Telephone Company has been organized with Frank Collins as president.

MANCHESTER, ME.—The Woodland Telephone Company, of Manchester, Me., has been incorporated with a capital stock of $10,000 to supply telephone service to the towns of Manchester and West Gardiner. The officers are: F. S. Collins, president; H. E. Emery, secretary, of Gardiner; J. T. Collins, treasurer, of Manchester Me., and James T. Collins, of Hallowell, Me.

HENRIETTA, MICH.—The Henrietta Central Telephone Co. has been incorporated with a capital stock of $550. Directors are T. J. Spears, J. Turner and A. White.

LAMONTE, MO.—The Lamonte Telephone Co., capital $5,000, has been chartered here by W. E. Files, W. F. Yankee, H. C. Mitchell, Arthur Bender, J. F. Staples and others.

PLATTE CENTER, NEB.—The Farmers' Independent Telephone Company, of this city, has been incorporated with a capital stock of $2,000.

JAMAICA, L. I., N. Y.—The Long Island Telephone & Tel. Co. has been incorporated with a capital stock of $500,000. The directors are E. A. Sneadeker, F. N. Green, and others.

LEONARDSVILLE, N. Y.—The Leonardsville Telephone Company, of this city, has been incorporated with a capital stock of $1,000. The incorporators are E. S. Brand, J. A. Crandall, A. M. Coon, all of Leonardsville.

HENNESSEY, OKLA.—The Center Township Rural Telephone Company, of Hennessey, has been incorporated with a capital stock of $1,000 by Frank Hassler, of Dover; Ben Thorne, William Beaman and others, of Hennessey.

INDEPENDENCE, OREGON.—The Mutual Telephone Co. has been organized with a capital of $1,000. R. Craven, president; W. W. Percival, vice-president; G. A. Hurley, secretary.

CLIFTON, TENN.—The Consolidated Telephone Co. has been incorporated with a capital of $50,000 by H. B. Stubblefield, of Nashville; W. N. Sloan, of Linden; T. S. Hughes, of Clifton, and others. These parties own telephone lines in Wayne, Hardin, Perry, Decatur and McNairy counties.

CLARKSVILLE, TEXAS.—The Home Telephone Co., of Clarksville, has been incorporated with a capital stock of $2,500 by John B. King, N. F. Deak and Hiram Glass.

MADISON, WIS.—The Belmont & Pleasant View Telephone Company, of Madison, Wis., has been incorporated with a capital stock of $5,000.

PERSONAL

H. J. PATTISON has been appointed manager for the Michigan State Telephone Company of Wyandotte.

E. E. LARHAM has been appointed manager for the Inter-Ocean Telephone Company at Penn Yan, N. Y.

CLARENCE HATCH has been appointed manager for the telephone company at Algoma, Wis.

J. A. PAGE has been appointed manager at Potterville, Mich., for the Citizens' Telephone Company, of Grand Rapids.

J. A. McCURDY has been appointed manager for the Cumberland Telephone Company at Mayfield, Ky.

V. K. HERLAN has been appointed manager for the Woodsfield Telephone Company at Woodsfield, Ohio.

FRANK BROWN, who was one of the most prominent telephone men in the State of Iowa and was interested in exchanges at Ottawa, Wichita, Emporia, besides operating a large number of toll lines, died recently.

C. L. HOWK, of the Local Telephone Company, of Norwalk, Ohio, has resigned to accept the position as manager of the Citizens' Telephone Co., of Plattsburgh, N. Y.

MISCELLANEOUS.

LOGANSPORT, IND.—At a recent meeting of the Cass County Surety Company which controls the stock of the Home Telephone Company, of this city, President Walter J. Uhl presented some statistics that showed the volume of business transacted by the local exchange on an average day of twenty-four hours. He stated that on November 20, an account was kept of every call into the office and it was found that there were 66,464. The busiest time came between eight and nine o'clock, when there were 6,837 calls.

DUBUQUE, IA.—Manager Stevens, of the Dubuque, & Interstate Telephone Companies, announces the opening up of a direct line running from here to Freeport.

ASHLEY, MICH.—The Ashley Improvement Associaton has taken action looking toward the building of a telephone exchange at Ashley.

BAY CITY, MICH.—President James E. Davidson, of the Valley Telephone Co., denies emphatically that the Valley Company has under consideration any proposition to unite or amalgamate with any other telephone company or system, or that such action was contemplated in the future. President Davidson attributes the rumors in this connection to the fact that the company is contemplating extensions of the Valley system.

HOUGHTON, MICH.—A telephone line is proposed to be run from Ontonagon to Matchwood, Bergland, Ewen and Bruce Crossings.

OVID, MICH.—The Union Telephone Co. has removed the exchange at Shepardsville, taking out the State lines, all calls on that line will go through the Ovid exchange.

ENTERPRISE, MO.—A meeting of those interested in the proposed City Mutual Telephone System was held at the city hall recently, and a committee was appointed to have a plant figured on.

BEATRICE, NEB.—A number of farmers living west of Pickerell have organized a farmers' exchange.

PENNINGTON, N. J.—The Pennington Telephone Co. has filed a certificate changing its office from Jersey City to this town.

CINCINNATI, OHIO.—The third attempt on the part of the Queen City Telephone Company to secure entrance to Cincinnati was begun recently in the Circuit Court. The original case was decided for the Queen City Telephone Company by the late Judge Nippert. This decision was reversed by Judge Littleford and the case was taken to the Circuit Court on appeal.

ECONOMY, PA.—F. N. Moser, a representative of the Economy Telephone Co. was in Berlin this week having a stock subscription for the purpose of establishing a local exchange there. Work on other extensions is being speedily pushed forward.

PITTSTON, PA.—The People's Telephone Company, of Pittston, was damaged, it is reported, during a recent storm to the extent of $50,000.

LEWISBURG, TENN.—The telephone line from Lewisburg to Yell has been completed. Every district in Marshall County, eighteen, is now connected by telephone with the county capital.

PARIS, TENN.—The Legislative Council of Paris has granted to local capitalists a franchise to establish and conduct a telephone system in Paris for fifty years.

CHASE CITY, VA.—A telephone line is being considered between this place and Red Oak.

NEWBURG CENTER, VT.—The Newburg Center Telephone Company has built 90 miles of lines this past year and expects to eclipse this next year. This company claims to have the largest free exchange in the State.

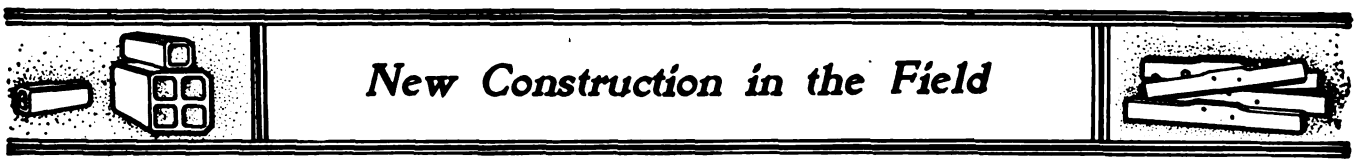
BENTON, WIS.—A plan is on foot among the progressive citizens of this town to put in a local telephone exchange.

UNDERGROUND.

SPRINGFIELD, ILL.—The Inter-State Telephone Company has a force of men at work laying an underground 200-wire cable from the office on Monroe street, east on Capitol avenue to Eleventh street, thence south to South Grand avenue. The new connection will accommodate the increased business south of the avenue.

PARIS, TENN.—The Paris Telephone Co., capital $25,000, will put in a new telephone system, placing the wires underground.

GREEN BAY, WIS.—The Valley Telephone & Tel. Co. is constructing an underground system in this city.



BLUE RIDGE, GA.—W. G. Ownby, of this city, will install a telephone system at Lafollette.

DANVILLE, ILL.—The Vermilion County Telephone Co. is installing a new switchboard with a capacity for 2,800 lines.

EDWARDSVILLE, ILL.—The Kinloch Telephone Co. is changing the location of its exchange and overhauling its system.

ROCK ISLAND, ILL.—The Chicago, Rock Island & Pacific R.R. is building a telephone line between Denver, Colorado Springs and Goodland, Kan.

LA PORTE, IND.—The La Porte Telephone Co. is building a permanent line to East La Porte. Forty-foot poles are being erected and the company will soon be ready to give the best of service to the citizens of East La Porte.

DES MOINES, IA.—The Mutual Telephone Company is putting its wires underground, and has entered upon the work of substituting cable leads for open wire, overhead construction, using 45 miles of lead coated cable.

ELDON, IA.—The Eldon Telephone Company contemplates a number of improvements to its system, including considerable cable work.

STUART, IA.—The Mutual Telephone Company is considering a new exchange.

WESTBROOK, ME.—The Northeastern Telephone Company is making rapid progress on the installation of its conduits and expects to install a switchboard at once.

CITY OF MEXICO, MEX.—A private telephone system to connect the National Palace, Chapultepec castle and the private residences of President Diaz is to be installed under the direction of Oliver Lopez Araiza, an electrician.

HART, MICH.—The Lake Shore Telephone Company, with headquarters at this town, has installed an automatic system at Pentwater.

HOPKINS STATION, MICH.—The construction gang of the Citizens' Telephone Company is at work in this township, repairing and improving the property recently purchased from the West Michigan Telephone Company. Since the Grand Rapids company assumed control the Citizens' exchange has grown to such an extent that the company decided to put Hopkins exchange on the direct copper circuit, which it is now installing between Allegan and Grand Rapids.

LAINGSBURG, MICH.—A rural telephone line is being built from the village to De Witt.

MULLIKEN, MICH.—The Citizens' Telephone Co., of Grand Rapids, is rushing its link line between Lake Odessa and Grand Ledge. Poles are up and wire will be strung to Mulliken next week.

DASSEL, MINN.—The Dassel & Collinwood Telephone Company is now working on an extension of its line into Ellsworth.

DEXTER, MINN.—The Farmers Telephone Company is putting in a new line between Dexter and Brownsdale.

FAIRBAULT, MINN.—Work has commenced on the construction of a rural telephone line from Fairbault to Shieldsville.

INTERNATIONAL FALLS, MINN.—The Rainy River International Telephone Co. intends to install a telephone system in this village.

LESUEUR, MINN.—The Farmers' & Merchants' Mutual Telephone Company has just completed and opened a service line from this city to Belle Plaine.

SACRED HEART, MINN.—Carl Anderson contemplates installing a local telephone exchange.

ANACONDA, MONT.—The Big Hole Telephone Company will connect with the Anaconda exchange in the near future.

CARLSBAD, NEW MEXICO.—The Public Utilities Company, an organization of Carlsbad capitalists, will construct a telephone line between this city and Artesia.

MOULTONBORO, N. D.—The Citizens' Telephone Company contemplates extending its line in the spring.

NEW BOSTON, N. H.—The work of setting poles for the new Francestown Telephone Company, in charge of Walter C. Johonnet, is progressing.

BARTON, N. Y.—The Ross Hill-Barton Independent Telephone Company is building its lines and will install the telephones as soon as possible.

BERKSHIRE, N. Y.—The Northern Tioga Telephone Company is extending from this village to Rawson Hollow, and will build a line from Hartford Mills.

FULTON, N. Y.—The Fulton Telephone Company is making arrangements for extensive improvements to its line. The company has about 300 telephones, and there are 75 new orders, but it is unable to accommodate this number at present. By the improvements which the company intends to make, it can easily handle 800 telephones.

MIDDLE ISLAND, N. Y.—The Suffolk Telephone Company has started the construction of a line to this village.

RICHFIELD SPRINGS, N. Y.—The Interstate Telephone Company has begun work on its line to Middleville by way of Eatonville and Elm Grove. At Middleville connections will be made with the wires of the Herkimer County Telephone Company.

SCHENECTADY, N. Y.—The Schenectady Railway is about to install a telephone system on its line.

LITCHVILLE, N. DAK.—The Litchville Rural Telephone Company will extend its Farmers' line in the near future.

MINOT, N. D.—The Northern Telephone Company has extended its lines to Rolla.

BELLAIRE, OHIO.—The National Telephone Company is at work on its new building on Guernsey street.

BROKENSWOOD, OHIO.—The Bucyrus Telephone Company has extended its lines to this village and will establish an exchange. A line is being built to Sheffield.

PIQUA, OHIO.—At a recent meeting of the directors of the Piqua Home Telephone Company it was decided to begin work at once on the erection of about 10,000 feet of additional telephone cable.

YELLOW SPRINGS, OHIO.—The Citizens' Telephone Company is constructing a farmers' line northwest of Yellow Springs, and about twelve new subscribers will be added to the local exchange, making abtu 148 subscribers in all.

ALTOONA, PA.—The United Telephone Company contemplates extensive improvements to its rural lines in the near future.

WESTCHESTER, PA.—The United Telephone Company is erecting a new pole line which will carry a number of new circuits, necessitated by its increased business.

FAULKTON, S. D.—Mr. J. H. Hays, manager of the Central Telephone Company, contemplates making extensive improvements in the system.

MADISON, S. D.—The Orland Telephone Company will construct a telephone line from Orland to this city. P. M. Benmer is president.

SALEM, S. D.—The Independent Telephone Company, of Sioux Falls, is building its line into Salem.

LA FOLLETTE, TENN.—W. G. Ownby, of Blue Ridge, Ga., contemplates putting in a telephone system at this place.

ALVIN, TEXAS.—The Alvin and Angleton Telephone Company will extend its line to Friendswood, in Galveston county.

BEDFORD, VA.—The Bedford & Campbell County Telephone Company is constructing a line from Coffee to Forest. This line will be utilized very generally by the farmers in the community traversed.

MIDDLEBURG, VT.—The Addison County Telephone Company is extending its lines to this village.

NORTHFIELD, VT.—The Northfield Telephone Co. is making extensive repairs to its system.

CHEHALIS, WASH.—The Home Telephone Co. will connect its system with a line that will be built by the residents of Alpha, a town about 20 miles away. The Home Company is also constructing several other rural lines.

WILBUR, WASH.—T. B. Seaton, owner of the Seaton Ferry, is interested in the construction of a telephone line from his ferry to Wilbut.

The 1900 Dry Battery

THE most needed quality is reliability. No one wants a battery that will respond all right for a week or ten days then "suddenly go out of business." Another requirement is that it shall continue "strong" during its life. These two requirements besides many others are characteristics of

1900 BATTERIES

We guarantee them not to freeze, leak or break; we warrant them to work with a strong, steady current during their life (anywhere from six to eighteen months).

They are compact, always ready. They are better than wet batteries—no slop, no repairs, no breakage. Any one can replace a worn out one at a moment's notice. They can be carried anywhere—always ready for instant use.

THE AMERICAN TELEPHONE JOURNAL

"Where is the Fool Killer?"

"It is with great pleasure that we noticed another evidence of your energy in last week's issue of THE AMERICAN TELEPHONE JOURNAL under the title, 'Where is the Fool Killer?' Too much cannot be said in praise of the way in which this matter has been handled. On December 8th there was received in our office a circular letter about the proposed consolidation. The writer at that time considered the advisability of communicating with you relative to giving this matter the lie, but considered the time was too short to have anything placed in last week's issue. It is characteristic of your paper to take up affairs of vital interest to the Independent movement, but in this case you seem to have been unusually energetic, and as such energy is timely, we wish to congratulate you."

"Yours very truly,
"ONTARIO TELEPHONE COMPANY,
"(Signed) J. F. STOCKWELL, *Gen. Mgr.*"

A Small One?

Yes, and the first one; but all great things start from small beginnings.

This is the first MONARCH board placed in operation and it used but 10 drops and jacks. Since then, just two months ago, we have sold over ,000 drops and jacks installed in boards. The smallest is here shown; the largest has 300 drops and jacks. It will interest you to get a complete description of the

Monarch Switchboard.

It will pay you to get our prices.

INTERSTATE CONVENTION VOTES FOR CONSOLIDATION.

By Telegraph to THE AMERICAN TELEPHONE JOURNAL.

AUDITORIUM CONVENTION HALL,
CHICAGO, Dec. 15.

THE fight for the consolidation of the two national Independent telephone associations has been won. The Interstate Association, at its convention here, has voted in favor of the proposition. The advocates of consolidation had a substantial majority from the start, and when it came to a vote their triumph was complete.

A committee of five was appointed to arrange the details of consolidation, and to meet a similar committee of five from the National Telephone Association of America. The joint committee was empowered to call a convention of the two associations, at which the general plans under which the consolidation is to be effected are to be presented for final ratification.

The committee appointed to arrange for consolidation consists of:

Theodore Gary, of Macon, Ga.
L. L. C. Brooks, of St. Paul, Minn.
H. F. Barnhart, of Rochester, Ind.
E. M. Coleman, of Louisville, Ky.
C. E. Hull, of Salem, Ill.

The convention was held at the Auditorium Hotel, Chicago, on Dec. 13, 14 and 15. The meeting was called to order the first day by President Barnhart. After attending to business on hand, the main topic of the convention was the consolidation of the association with the national body. The general trend of events has been toward this consolidaton, since the success of the Independent movement necessitated concerted powers which could only be attained through the medium of one representative body.

Now that this much-wished-for result has been consummated, the future welfare of the Independent movement is assured; and an equally important point gained is, that an organization as well officered and managed as the Bell will be brought to bear upon the cause of any Independent company that may be in danger of the opposition. The organization of the whole country in accordance with the "Ohio Idea" will now be aggressively pushed, so that immediate benefits may accrue where, in the past, the Independent movement has only been able to move in a restricted manner; the new order of things will open up and develop territory in a most aggressive way, and the tactics of the Bell company, which have tended to hinder development, will now be met with an organization as powerful and resourceful as itself.

That the time is now ripe for such a movement is only too evident. Here and there throughout the country the Bell has been singling out the most defenseless companies, and, like a vulture swooping down upon its prey, has gobbled up the faint-hearted. Its tactics have been mostly under cover, and so devised as to shoot terror into the hearts of its victims. Its newest plan, and one of the most insidious, although but partially successful, is to admit itself beaten, and to offer to withdraw from a territory upon conditions of securing the toll and long-distance business of the company. Just why some of the Independents have allowed themselves to be buncoed by such a scheme is not apparent, but it is also certain that the consolidation of the associations will put a stop to this class of business and form an overwhelming barrier to future marauding expeditions of the Bell minions.

It is to be hoped that no further delays will be allowed in the formation of the plans of consolidation, and also that the committees which have been appointed to effect the merger will be able to do so in as amicable manner as possible.

A STUDY IN TRAFFIC.

By The Traffic Manager.

IN the preceding article, the methods commonly employed in making a peg count for the purpose of determining the load line upon a telephone exchange were described. As an instructive illustration a number of results from actual experience have been obtained and will be presented for the information of our readers.

These statistics have been gathered from as wide a field as possible, embracing peg counts taken from large and small exchanges, and from both Independent and Bell companies. Reports of the work of something over 1,000 operators, under a great variety of conditions, are included. A rough classification has been adopted whereby large cities are understood to mean those of one-half a million inhabitants or over; medium-size cities embrace, say, those with fifty thousand to five hundred thousand; towns are understood to mean a population of from ten to fifty thousand, while villages are such as are of a less size.

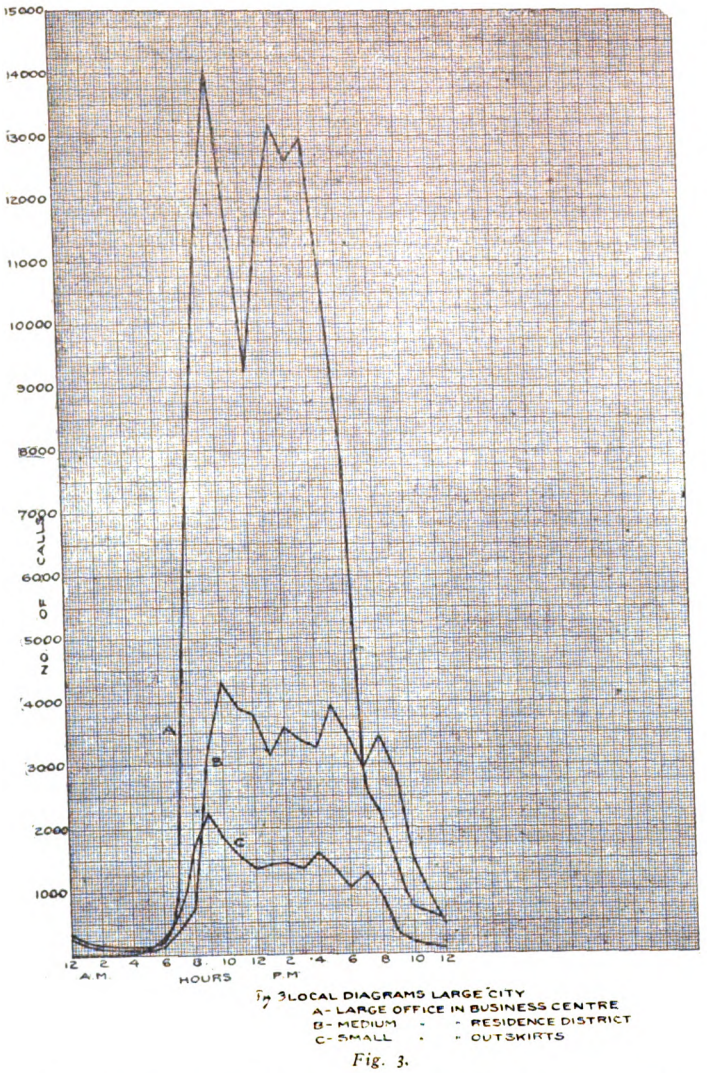

Fig. 3. LOCAL DIAGRAMS LARGE CITY
A- LARGE OFFICE IN BUSINESS CENTRE
B- MEDIUM " " RESIDENCE DISTRICT
C- SMALL " " OUTSKIRTS

Fig. 3.

The graphical method which consists in plotting the results upon a sheet of cross-section paper was the earliest form to be used, and has the advantage of presenting the progress of business from hour to hour in a manner readily to be grasped by the eye.

Fig. 3 is a diagram taken from an exchange in a large city. Three curves are shown upon this sheet. Curve *A* depicts the business of an office of from 4,000 to 5,000 subscribers in the center of the business district. Curve *B* gives the returns from a medium-sized office, say from 2,000 to 2,500, located in a mixed residence and shopping district, while curve *C* that for a small office of from 500 to 800 subscribers in the outskirts. In this diagram, as well as in all others which follow, the lower horizontal scale contains the various hours of the day, while the left-hand vertical scale gives the number of calls which were received during the successive hours. From midnight to 6 A. M. it is noteworthy that all three curves closely approach the base line, showing very little business. The minimum point occurs between 3 and 4 A. M. About 5 o'clock the load begins to increase, at 6 in all the offices it takes a sharp upward turn, reaching the maximum in the business district at 10 A. M. and in the outlying residence district at 9. From 10 to 12 the load drops sharply, showing the effect of the noon hour. In the afternoon a second peak occurs, but it is curious that this peak rarely rises to the same height as that which is attained by the load in the morning. After 4 o'clock the load line in the business district rapidly declines, the line moving almost continuously downward until midnight. In curve *B* a small peak occurs about 8 o'clock, which is due to traffic arising from making social engagements.

Fig. 4 is the diagram from an exchange in a medium-sized city. Curve *A* relating to an office in the business district, and curve *B* to one in the outskirts. As the offices were considerably smaller in size the load line is much lower than that shown in Fig. 3, but the noteworthy feature is the difference in the shape of the curve. Proportionately the load is steadier, as there is less relative difference between the peaks and hollows. This is even more marked in the case of curve *B*.

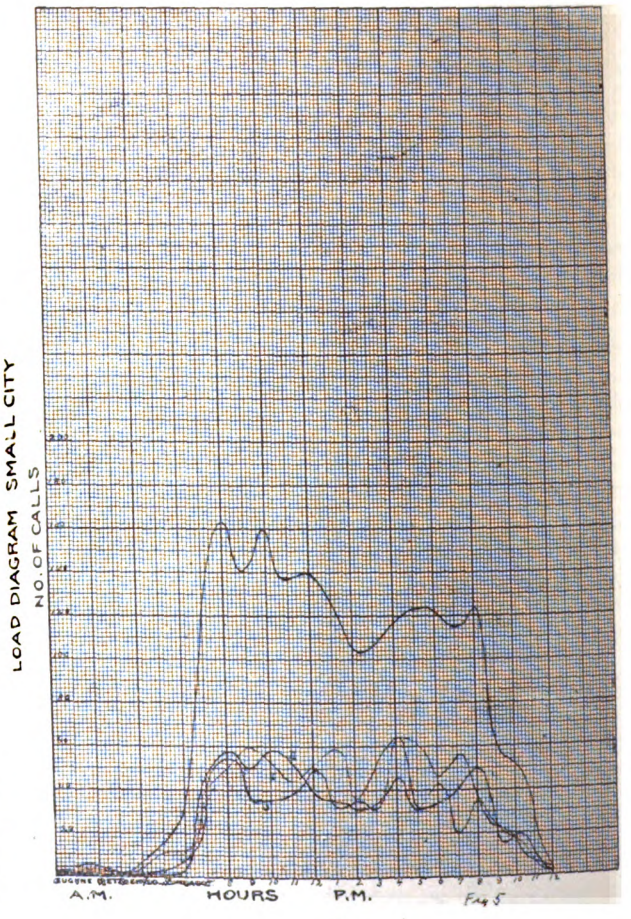

Fig. 5.

Fig. 5 is the load line from a town of about 10,000 inhabitants in a farming district. Upon this diagram, as well as upon the succeeding one (Fig. 6), the load line of each of the individual positions of the three operator boards which served the town are

Digitized by Google

plotted. Fig. 5 is peculiar in showing two peaks, one at 8 and one at 10 o'clock in the morning, but a consideration of the habits of a rural town of this kind shows that these peaks arise from the fact that a farming community, particularly one (as was the case in the diagram under consideration), where the railway service gave two early morning trains, transacts the bulk of its business at an early hour. The lowest point in this load line occurs about 2 o'clock, which represents a different condition from that which arises in the larger cities. The afternoon peak occurs between

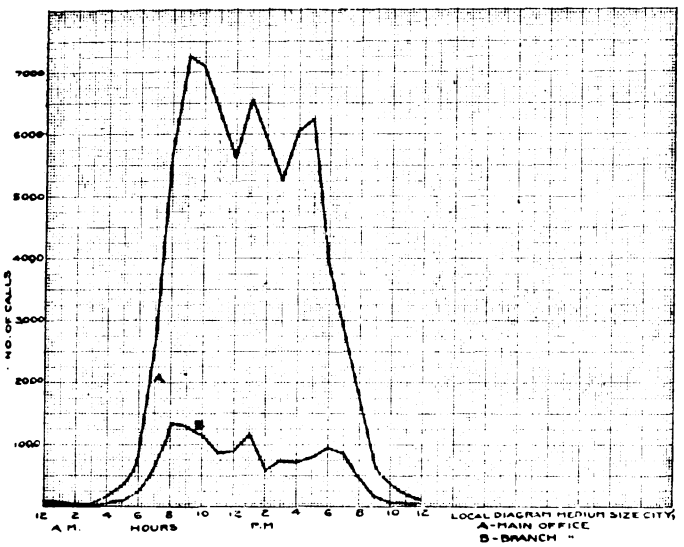

Fig. 4.

5 and 6, and in the evening at 8 o'clock there is the usual elevation due to social calls.

Fig. 6 is the load diagram of a manufacturing and railway town about the same size, and not far distant from the one represented in Fig. 5, but the load line is entirely different. There is a sharp peak at 9 o'clock and another sharp one at 5 o'clock. There is also a very distinct peak at 10 P. M. The 9 o'clock and 5 o'clock peaks represent respectively the hours of the arrival and departure of a number of trains, while the 10 P. M. peak represents business transacted by the railway shops, for it was the custom in this town for the night shift of employees to come on at 10 o'clock, and the business originated at this time is due to the change in force which then took place.

It would be easy to multiply diagrams of this kind to any extent, but sufficient examples have been given to illustrate this

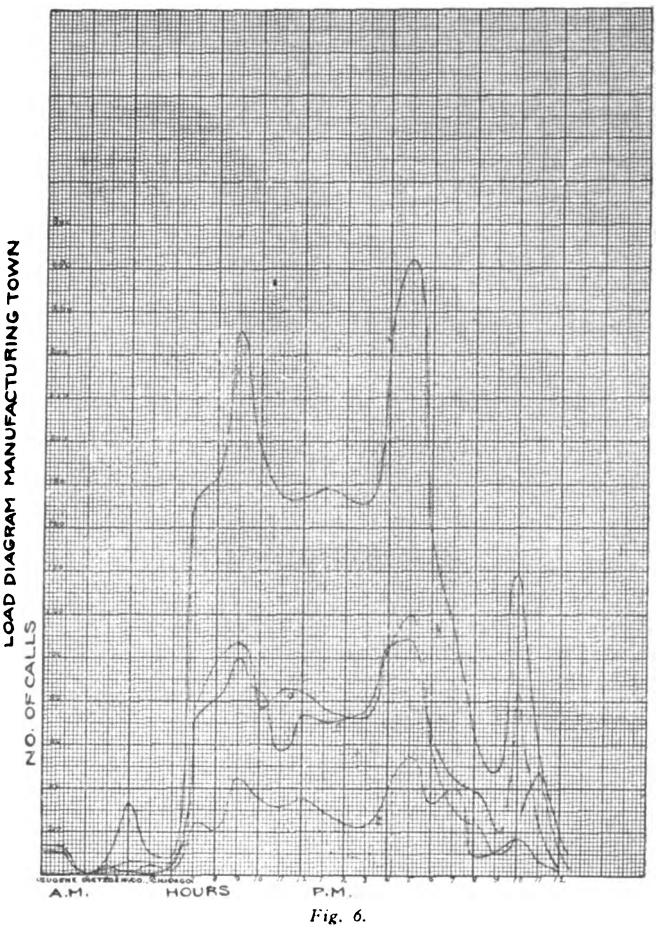

Fig. 6.

method of tabulating results of the peg count and to exhibit the lessons which the compilation of a series of diagrams of this kind can convey.

TELEPHONE COURSE AT PURDUE UNIVERSITY

THE third years' course at Purdue University, Lafayette, Indiana, which has just commenced shows a large increase in enrollment over that of last year. This department is considered by the university as one of the most valuable adjuncts to the study of electrical engineering and is consequently carried out in a most thorough manner. It was introduced at Purdue by Prof. W. E. Goldsborough, who was chief of the department of electricity at the St. Louis Exposition, and who holds the chair of electrical engineering. Prof. J. C. Kelsey, however, is at the head of the department of telephone engineering. He has had a practical experience extending over several years with both Independent and Bell companies. Besides being an enthusiastic advocate of telephone engineering for technical schools he has caused several of them, including the Ohio State University and the School of Technology, at Worcester, Mass., to consider the opening of a similar department.

The study is a part of the course in electrical engineering and may not be taken up by itself. For this reason many applications received from men who wanted to take the two-year course in telephony alone have been refused. However, juniors and seniors may take it in preference to thermodynamics and steam engine and boiler work. Prof. Kelsey has now twenty-five students in his class, with the prospect of 100 per cent. increase next year. Manufacturing concerns at first aided the department by giving or loaning equipment, but the University is now independent, buying what it needs and the best the market affords. The laboratory contains almost every type of switchboard and telephone apparatus, which are dissected and studied from beginning to end. The introduction of the automatic telephone created a great deal of interest in the department since it obviously reduced the working force at the switchboard and created the necessity for more expert telephonists to take charge of the lines and exchanges. A demand for these men is growing and the chances for the employment of Purdue's graduates are always good. The students use a fully-equipped exchange having an ultimate capacity of 1,000 lines.

MOTION TO RAISE BOND.

ANOTHER point in the fight of the Illinois Manufacturers' Association against the Chicago Telephone Company has been decided adversely to the latter in the Circuit Court. Judge Tuley has refused a motion of the defendant to force the association to increase its bond of $10,000, filed in court as an indemnity against loss to the telephone company. Allegations were made by the company that many of the 1,100 complainants in the suit to lower telephone charges are irresponsible financially.

A HOME MADE POLE CHANGER.

By Arthur Riche.

EXPERIENCE has shown that a pole changer is an exceedingly desirable and economical device for the small exchange, whose small size is hardly sufficient to warrant the necessary expenditure for the electrical machinery required in the installation of a ringing dynamo. There are very many instances, particularly as the small exchange increases its capacity, when it is practicable for the wire chief to construct a pole changer out of materials at his hand, and thus avoid the expense of purchasing a machine outright. So, the object of this article is to describe a method that has been successfully put into practice for accomplishing this result.

The materials required are: A board for a base, 5" × 9"; one 3" gong iron box vibrating bell; one ½ M. F. condenser; one single contact relay of not over 80 ohms resistance; six brass binding posts, such as may be taken from old dry batteries; eight platinum hook-switch points; four strips of brass, ⅜" × 1¼"; six inches of light watch spring; a few screws, etc. The bell should be prepared by cutting the frame at the edge of the gong and cutting the hammer rod so as to leave ½" of stub. To this stub solder a piece of No. 12 iron wire 4" long, which has been flattened slightly.

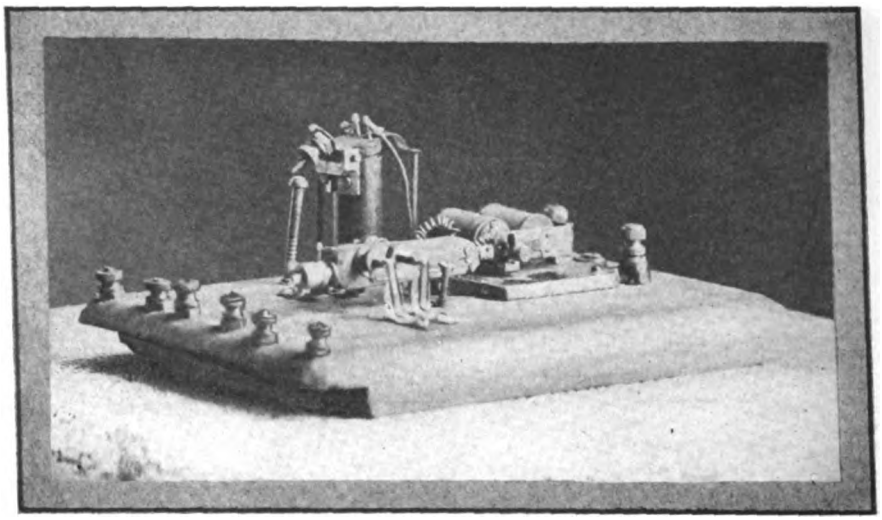

Fig. 1.

Slip over the wire a piece of hard wood, 3" × ¾" × ⅛", which has two 3/32" holes ¾" apart, as shown at *e*. It may be well not to dress the wood down to dimensions until after it is bored and in place. Place in the two holes two contact pins, made by cutting off the heads of two binding posts and soldering to each end of both platinum points. Place some sort of a light weight on the end of the vibrator, with which to govern the rapidity of its vibration, which should be about twenty complete vibrations per second.

Screw the vibrator to the base, which has been smoothed and varnished, and so adjust it that the points shall be one inch from the base. Cut four pieces of brass, as shown at *a*, and solder to them pieces of spring, as at *c*, and bend together, as at *b*. Bend the spring so it will have only a slight tension against the brass. It will be necessary to draw the temper in the springs, as they are too brittle without. Carefully punch the holes for the platinum points and solder them in on the back, as the springs will not bear much riveting.

Screw these contact brushes to the base so that the points on the pins will strike the points in the springs quite firmly when the vibrator is run with one cell of dry battery. Be sure that both contacts on one side make and break at exactly the same time.

Mount the relay in the most convenient manner and make all connections, as shown at *e*. Connection to the contact pins should be made by means of wires brought to the end of the vibrator tongue and connected to posts driven in the base, by flexible cords or coils of wire, as is plainly shown in Fig. 2. The condenser may be mounted on the bottom of the base and the machine raised on short legs or the connections brought out to binding posts, as shown in Fig. 1. The machine will work much better if held firmly and not allowed to vibrate as a whole.

While this machine may appear crude in comparison with the purchased article, when carefully made it will give very little trouble and requires no attention. We have one in our office, made from odds and ends, which has been running for some time without a stop and ringing the longest, hardest, country lines. We use three cells of gravity battery, connected in mul-

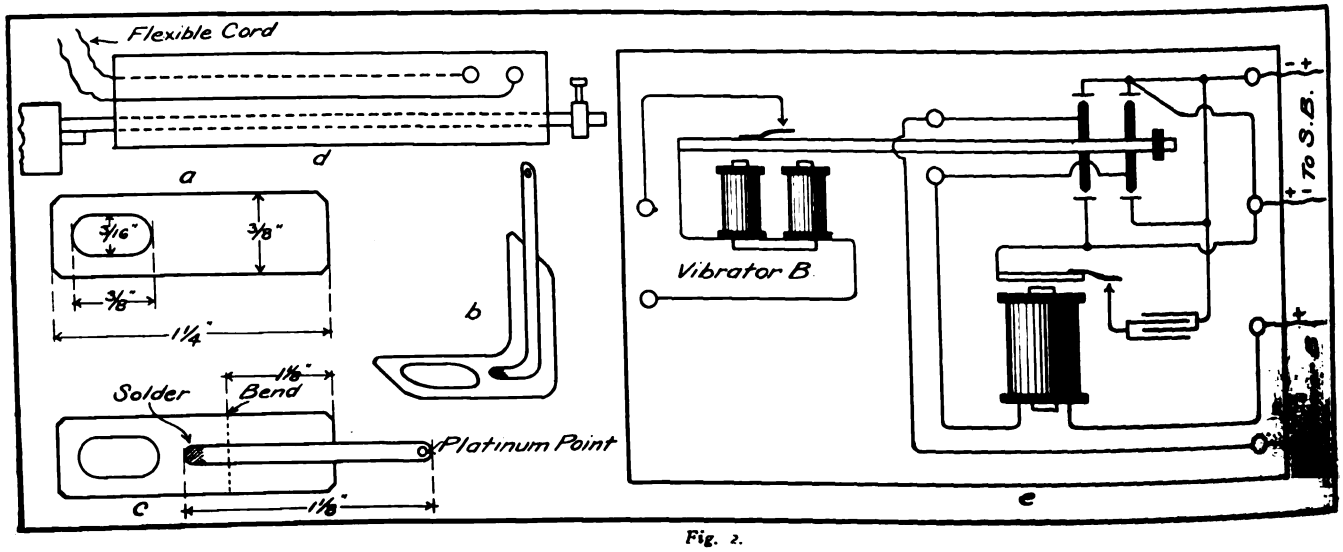

Fig. 2.

Digitized by Google

tiple, to run the vibrator, and fifty cells of "1900" battery for the power, and they do the work in good shape.

When the materials are bought outright the cost will stand about as follows, as compared with the $25 that a factory-made instrument would cost:

Base	$0.25
Bell	.35
Condenser	1.00
Relay	2.00
Platinum points	.80
Brass and binding posts	.25
Screws, wire, etc.	.25
	$4.85

Even this small cost may be greatly lessened in many instances, for a large part of the required material is found in the junk heap of nearly every exchange. A very good substitute for a relay may be made from an old drop by soldering on a piece of brass for a contact and a binding post for a counterbalance. Or even the windings of an 80-ohm bell may be made to serve.

A PRACTICAL WAY TO TURN A CORNER

By William H. Elges.

QUITE frequently the construction of rural lines does not meet with the attention and consideration for its various details as it should, and consequently where a line should have cost a stated amount, before it has been completed the expenditure has been largely increased over the original estimate. The proper location of poles and their distribution with regard to strains and locality is as important as the switchboard, in fact even more so, because the various manufacturers design their apparatus for a certain specific end, and have used their utmost ability in engineering skill to secure results; whereas the builder of a rural line quite frequently has no further knowledge of the business than that gained by a casual examination of other pole lines or what he might have received from any books upon the subject.

To turn a corner in a simple manner and yet have the line

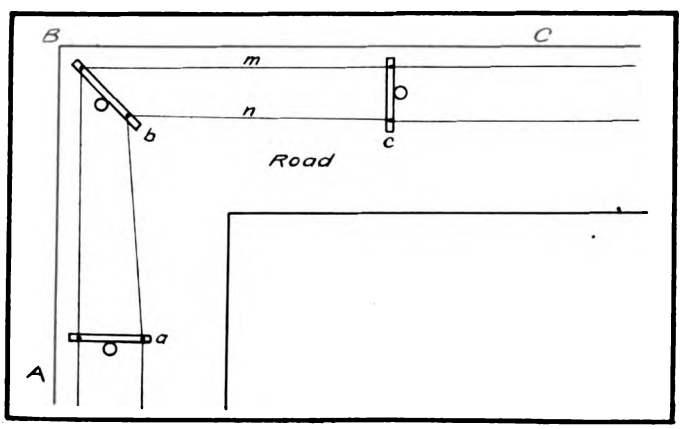

Fig. 1.

substantial is a very important part of its construction, and if not carried out with the best knowledge of line practice gives frequently a large amount of trouble. Aside from the matter of stringing the line there is the liability of crosses occuring at this point which result in a great deal of time and money being lost in cleaning. Take for example Fig. 1, in which *A*, *B*, and *C* represent a turn in the road and *b* the corner pole and for ease in describing let there be only two wires, *m* and *n*. Now, if *m* and *n* are 6 inches apart at *a* and *c* and the distance between the insulators at *b* is 6 inches, and also if the arm *b* has an angle of 45 degrees with the crossarms *a* and *c*, the distance of the wires *m* and *n* from each other at *b* is only 4.2 inches, which is 2 inches closer than at other points along the line. There are two ways of overcoming this difficulty, one is shown in Fig. 2 where *A*, *B*, and *C* represent the turn in the road and *d* and *e* are poles used at the corner. With this method the wires *m* and *n* are only brought closer together between the arms *d* and *e* and in such a short distance there is no danger of crossing.

This construction, however, requiring two poles and additional crossarms and guide wires is unnecessary and too costly, except in extraordinary cases.

Fig. 3 represents the best and most economical method of turning the corner. In this case *A*, *B*, and *C* represent the turn

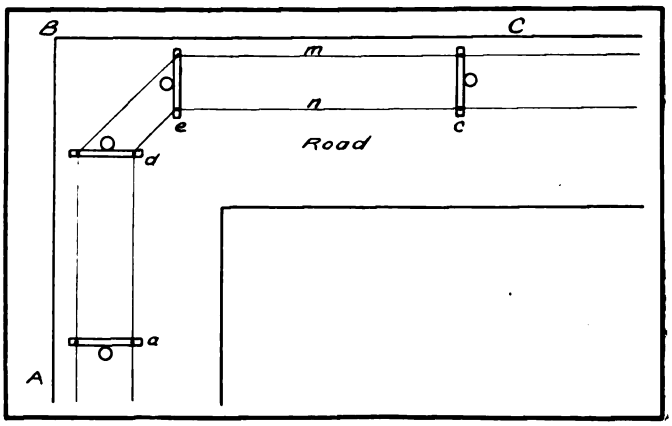

Fig. 2.

in the road, and *b* the corner pole. Upon *b* mount two crossarms at right angles *x* and *y* so that *y* is parallel to *a* and *x* to *c*. The wires *m* and *n* and *m'* and *n'* should be run in the usual manner and dead ended at the knobs at the crossarms at *b*. To cross connect the lines, it is good policy to use insulated wire which renders the possibility of crosses from any cause almost impossible. When line construction similar to this is used the maximum efficiency and the minimum of cost is ob-

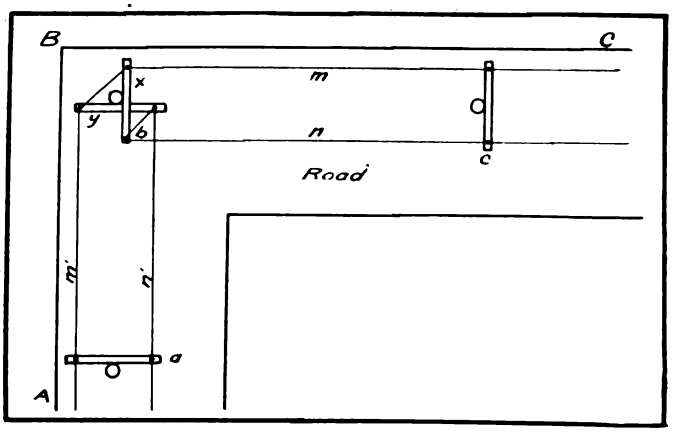

Fig. 3.

tained and the necessity for using more than one guy wire is done away with.

It has been the writer's purpose to describe in a few words one of the simple problems in line construction with the idea of showing where money can be saved both in construction and maintenance, since it is only by excellence of construction that the great bugbear of a telephone system "maintenance" can be kept down.

IN THE OPERATING FIELD.

CENTRAL NEBRASKA TOLL ASSOCIATION ORGANIZED.

AT a meeting of the leading Independent managers and stockholders of the State, held recently, the Central Nebraska Toll Association was organized for the purpose of generally bettering conditions. At the meeting was represented telephone interests in the leading counties of the State possessing about 1,000 miles of toll lines. The companies represented were the Hamilton County Telephone Company, the Grand Island Telephone Company, Kenesaw Telephone Company, Sheldon Telephone Company, Ravenna Telephone Company, Kearney Telephone Company, Kearney & Northwestern Telephone Company, Phelps County Telephone Company, Elm Creek Telephone Company.

LEWIS COUNTY, MO., TELEPHONE COMPANY ISSUES NEW DIRECTORY.

THE Lewis County, Mo., Telephone Company has recently issued a new directory which more than anything else illustrates the growth of Independent lines in Missouri. This directory consists of 114 pages and lists upwards of 1,500 names. A separate page or pages is devoted to each exchange and all toll and party lines are arranged separately. An alphabetical list is given of all subscribers so that the name of the party, line, and signal, can all be obtained at a glance. The Lewis County Telephone Company has exchanges in the following places: Alexandria, Antioch, Argola, Benbow, Benjamin, Bunker Hill, Canton, Colony, Deer Ridge, Derrahs, Durgan, Durham, Edina, Emerson, Ewing, Gregory, Hester, Hahoka, Knox City, Labelle, La Grange, Laura Lewiston, Maywood, Monticello, Neeper, Nelsonville, Newark, Palmyra, Santuzza, Sellers, St. Patrick, Steffenville, Lalor, Ten Mile, Salona, Wayland, Williamstown, Winchester, Wyaconda. Besides the general system over 100 county and toll lines are given.

The Lewis County Telephone Company has made a very large number of improvements in the past and contemplates extensive additions to its system for next summer.

GROWTH OF HOME COMPANY AT FORT WAYNE.

A RECENT report issued by the Home Telephone Company of Fort Wayne shows a very creditable growth and financial condition. At present there are over 3,300 telephones installed and new contracts are being secured at an average rate of fifty a month. The company owns its own building worth $40,000 and it has $32,000 in the sinking fund for the redemption of $250,000 outstanding 6% bonds. Six and a quarter per cent. is set aside yearly for the sinking fund and 2% is paid on the stock. At the recent election Charles S. Baseh was reelected president, W. L. Moorlling secretary, and M. B. Fisher treasurer.

INDEPENDENT SYSTEMS AROUND JONESVILLE, MICH., STAND FIRMLY AGAINST BELL.

AT a recent meeting of Independent telephone men interested in exchanges in the neighborhood of Jonesville, Mich., a strong stand was made to oppose the Bell Company. John Fitzsimmons, the manager of the Hillsdale exchange, introtruced a proposition whereby the Independent rural lines would connect with the Bell Company. After occupying the floor for a considerable time explaining an interchangeable contract he could make with the Bell, the following speakers made addresses calling attention to the success the various Independent companies had had and plainly demonstrating the undesirability of such a contract: J. C. Smith, manager Jackson City Tel. Co.; W. H. Smith, president Coldwater system; E. L. Miller, manager Wolverine Tel. Co., Coldwater; Samuel Knect, Lester; Edward H. Rice, Alagansee; Whit Shepard, South Allen; L. H. McClave, John Condra, Allen; Ward Noble, John Babcock and C. A. Bailey, Quincy; D. B. Scripture and Eber C. Farwell, of Butler.

The chairman then called for a vote upon the matter, asking all those who were satisfied with their present system and were in favor of cutting out all the Bell connections and all switches that had Bell connections to stand up. Every person in the room stood up but Fitzsimmons.

RESULT OF COMPETITION IN GREENFIELD, IND.

THE result of Independent competition is well illustrated by the results obtained at Greenfield, Ind. Since the Citizens' Telephone Company entered the field a year ago the long distance rates to Indianapolis have been reduced to 15 cents, which is a rate much lower than is charged by the Bell company to points a great deal nearer. The popular feeling is in favor with the Independent company, which is giving excellent service, and it seems that the city departments will hereafter rely entirely upon the Citizen's service.

OPERATORS RULES OF ROCHESTER TELEPHONE COMPANY.

THE Rochester, N. Y., Telephone Company has recently issued a book of rules for the guidance of its operators. These rules are intended to cover almost every condition of operating and apparently have been compiled with a great deal of care. The wording of the various items has been so arranged as to exactly indicate what is meant without the expression being harsh and blunt, as is unfortunately quite often the case. A good deal more attention to rules would be general were they compiled with a careful regard for language in expression than is the case when the imperative character of the phrases is brought out by the too frequent use of must and shall.

Besides the rules a list of numbers and parties is printed which each operator is requested to memorize. These include large business houses, fire, police and hospital telephones, theaters, express, freight and passenger offices, messenger companies, newspaper numbers and the offices of the gas and electric companies, besides the calls of the various departments of the telephone company. The book is tastefully gotten up in a size easily carried, and is intended to be a *vade-mecum* for the best interests of the operating force.

OHIO VALLEY COMPANY RECONSTRUCTING SYSTEM AT BELLAIRE.

WORK on the installation of the new plant of the Ohio Valley Telephone Company at Bellaire, O., which was commenced recently, is now progressing rapidly, and it is expected to have all the underground work completed before cold weather makes such work impossible. It is a fact not generally known that the company will install an entirely new system in every detail and not a portion of the present equipment will be used. The new plant will be constructed upon the most up-to-

Digitized by Google

date plans and will be equipped with the latest improved apparatus. Everything will be new, from the wire up to the central office building, which is now in course of erection.

The contract for the installation of the new system has been let to the Mountain State Electric Company, of Wheeling, and the work is being done under the personal supervision of Mr. Frank Hall, of that company, who recently returned from Salt Lake City, Utah, where he installed a large plant. He is being ably assisted by H. C. Fuhr, of Bellaire, who recently resigned his position as chief electrician for the Bellaire Steel Works. The new cables to be used by the company will on certain streets of the city be placed under ground, the excavating for the conduits being now in progress. The construction of this work has been delayed somewhat by the inability to secure workmen, since Mr. Fuhr refuses absolutely to employ any class of foreigners.

RESTAURANT TELEPHONE SERVICE IN INDIANAPOLIS NOTED.

"TELEPHONE while you eat" is the caption of the menu card at the Denison Hotel grillroom in Indianapolis. A system has been installed whereby patrons can telephone to their friends, make engagements, transact business, order a carriage or theater tickets without leaving the dining chair. This innovation is due to the enterprise of President George Fulwell, of the Denison, and it is proving quite popular.

NEW PLANT FOR CITIZENS' CO., OF COLUMBUS.

THE Citizens' Telephone Company, of Columbus, O., is doing its utmost to hurry the completion of its new building. This building will be four stories high, the upper floor being designed for the automatic switchboard. This room is 90 by 90 feet, and will afford ample space for the apparatus. The balance of the building, except the ground floor, will be occupied by the company for its offices.

The Citizens' Company was one of the first of the larger Independent companies in the State of Ohio, and from the commencement its success has been phenomenal. Hundreds of contracts have been received, which the company was unable to complete on account of lack of apparatus for periods varying from one to two months, notwithstanding the fact that the line and switchboard capacity was being continually augmented.

A large amount of the credit for this progressive company is due to its manager, Frank L. Bear, who has been with it since its organization, and has always pursued the aggressive policy which has helped to place the company where it is to-day.

THE P. & A. AT McKEESPORT.

THE Pittsburg & Allegheny Telephone Company has paid particular attention to the development of its exchanges in the territory tributary to Pittsburg, and in almost every instance has secured more subscribers than the Bell. At McKeesport, where it installed a new exchange last June, it has over 1,500 subscribers. At the time the exchange was opened the Bell company, which had been located there for years, had only 750 subscribers, and the Federal Telephone Company, the pretentious rear-end appendage of the Bell interest in Greater Pittsburg, had less than one-half that number.

Fully 75 per cent. of the P. & A. service at McKeesport has been installed on the nickle basis, which is proving immensely popular with subscribers and correspondingly profitable to the company, which is the pioneer in this method of service.

A SPARE PAIR RECORD

By Harold A. McMann.

A HANDY record for obtaining at all times a status of spare pairs in a cable or at a terminal is herewith shown and described.

The lay-out of the sheet is clearly indicated in the drawing; this may be either printed in a convenient book or adapted to the universal and flexible card system.

Suitable spaces are left at top of the form for the number of the cable, the name of street on which it runs and a line for brief remarks that may be found useful for noting the condition of the cable, and spaces for number of spares, district, etc.

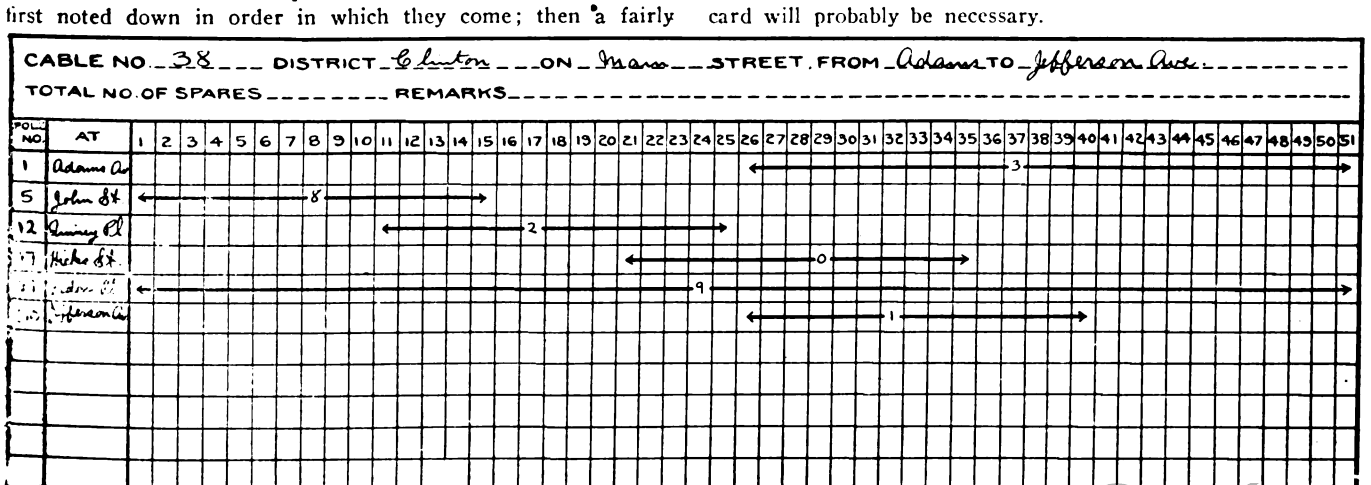
On the left hand side of the sheet columns are provided for the different terminal poles and streets at which they are situated.

The rest of the sheet is divided into fifty-one columns, each column representing a pair in the cable and accordingly numbered

The method of using this record is as follows: Suppose an aerial cable has been run upon a certain street and the report of the work turned in at headquarters. The different terminals are first noted down in order in which they come; then a fairly heavy line is drawn from the first pair in the terminal to the last and a small arrow placed at each end of the line. It is a good scheme in drawing this line to leave a small gap in the middle of it; this is for the accommodation of whatever spare pairs there may be in the terminal. They are generally put in pencil, and changed as required to keep the record up to date.

This record is also very useful to obtain the number of overlapping pairs between two or more terminals; the record being partially graphic, it is only necessary to glance at the lines where they parallel each other to obtain this information. Take poles 5 and 12 as an example. Pole 5 takes pairs 1 to 15 and pole 12 11 to 25; thus, between pairs 11 to 15 they parallel and consequently overlap.

The above-described record may be used for underground cables by increasing the number of columns for the pairs, a good plan being to run, say, from 1 to 51 on one-half the card and 52 to 101 on the other. If the cable is larger than 100 pairs more than one card will probably be necessary.



A Handy Cable Record.

INDEPENDENT SYSTEMS IN CARNEGIE PLANTS.

THE Pittsburgh and Alleghany Telephone Company has added another to its long list of signal victories over the Bell trust by capturing practically all the telephones in the immense works of the Carnegie Steel Company, at Homestead, eight miles above Pittsburgh on the Monongahela river. A total of 183 telephones have thus been transferred to the P. and A. service and will stay there for at least five years according to the contract. The Central District Printing & Telegraph Company, the Bell company in Pittsburg, has thus lost all but six of its telephones in these works. It will take 12,000 feet of telephone cable in addition to the wires to equip the plant. Just how badly the Carnegie Company wanted the P. and A. service is proven by the fact that it pays more for it than the Bell officials offered their service for.

The P. and A. company now controls the service in the Carnegie plants at Duquesne, where it replaced the Bell service over a year ago, and also has the Carnegie works at Youngstown, Warren and Niles, Ohio, and Sharon, Pennsylvania, in addition to several of the Carnegie plants in Pittsburg. Private exchanges have been installed in all these plants. This gives the P. and A. company practically all the Carnegie plants except those at Monessen and Donora, Pennsylvania, which have 12 and 14 telephones respectively.

The above news item should prove of interest to every Independent operator for several reasons. In the first place, it conclusively proves that the Independent companies furnish better service than the Bell. If it did not, the Carnegie Steel Company would never have considered it for a moment, and it is equally certain that it would not allow any suspicion of sentiment to alter its views. Secondly, it is reasonable to suppose that such big plants as these must be in constant communication with a very great number of parties. If the P. and A. couldn't have furnished the local service desired, it could not have secured the contract. Another determining factor was the ability of the Independent company to give long-distance connections. It isn't so very long ago when this would have been impossible, except in a limited way, but so much progression has taken place in long-distance line construction that, with few exceptions, every city and town in Pennsylvania, New York, Ohio, West Virginia, Indiana and Illinois can be reached over Independent lines, besides a vast number of towns and cities in the adjoining States not mentioned.

Henceforth it would seem that this cry of the Bell that "you can't get long-distance service without using our lines" will be ridiculous, and thus the last straw which gave the enemy any supposedly exclusive hold upon the telephone industry has been swept away.

ILLEGAL USE OF A TELEPHONE.

AN interesting case arose in North Carolina over the refusal of a telephone company to install an instrument in a disorderly house. The keeper of the house sought mandamus to compel the company to comply with her demands and accord to her the privileges afforded to other subscribers to the telephone exchange operated by the defendant in the town. It was admitted by the plaintiff that she was engaged in an illegal pursuit and demanded equal rights with other subscribers.

In its opinion the court said that it was true that a telephone company was a common carrier of intelligence and must operate without discrimination affording "equal rights to all, special privileges to none." The court continued: "But while it is true there can be discrimination where the business is lawful, no one can be compelled, or is justified, to aid in unlawful undertakings. A telegraph company should refuse to send libelous or obscene messages, or those which clearly indicate the furtherance of an illegal act or the perpetration of some crime. But recently in New York the telephone and telegraph instruments were taken out of 'pool rooms' which were used for the purpose of selling bets on horse races. Keeping an illegal house was an indictable offense at common law, and is still so in this State. One who leases a house for the purpose of its being kept as an illegal house, or with the knowledge that it will be used for that purpose, is indictable. A mandamus will never issue to compel a respondent to aid in acts which are unlawful.

"It is argued that a common carrier would not be authorized to refuse to convey the plaintiff because she keeps an illegal house. Nor is the defendant refusing her a telephone on that ground, but because she wishes to place the telephone in an illegal house. A common carrier could not be compelled to haul a car used for such purpose. If the plaintiff wished to have the telephone placed in some other house used by her, or even in a house where she resided, but not kept as an illegal house, she could not be disbarred because she kept another house for such unlawful and disreputable purpose. It is not her character, but the character of the business at the house where it is sought to have the telephone placed, which required the court to refuse the mandamus. In like manner, if a common carrier knew that passage was sought by persons who are traveling for the execution of an indictable offense, or a telegrapn company that a message was tendered for a like purpose, both would be justified in refusing; and certainly when the plaintiff admits that she is carrying on a criminal business in the house where she seeks to have the telephone placed the court will not, by its mandamus require that facilities of a public nature be furnished to a house used for that business.

"For like reason a mandamus will not lie to compel a water company to furnish water, or a light company to supply light to a house used for carrying on an illegal business. The courts will enjoin or abate, not aid, a public nuisance.

"The further consideration of this matter is not required of this application for a mandamus, but should be on an indictment and trial of the plaintiff for the violation of law so brazenly avowed by her."

ENGLISH TELEPHONE FACILITIES.

AN experiment, the issue of which will be watched with marked interest, is just now being conducted by the postal-telegraph authorities, reports Joseph G. Stephens, Consul, Plymouth, England. Its object is to ascertain how far it may be possible to make village post-offices serve the further purpose of public telephone-call offices. Six villages have been selected, and in these any one may now ring up a subscriber and communicate with him by telephone at the ordinary rates, which in this district amount to 12 cents for a three-minute conversation. If the person with whom communication is sought does not happen to be on the telephone list, the sender may telephone his message to the nearest post-office and have it delivered thence by express messenger. In the opposite direction—that is, from town to village—similar facilities will be available.

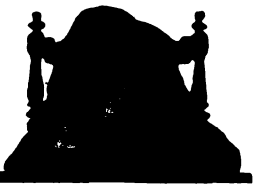
The Telephone in the Courts



Conducted by A. H. McMillan.

Readers are invited to submit questions on any point of Telephone Law. They will be answered and explained on this page.

GRANT TO INCOMPLETE INCORPORATION.

The organization of our corporation was not complete, the articles of association being all drawn, signed and ready for filing but not yet forwarded to the Secretary of State, when our franchise was granted. Is our franchise good or not? G. R. T.

A GRANT to a company whose organization is not complete is not void, because the franchise, though not technically complete, is practically so. Chicago Telephone Company vs. N. W. Telephone Company, 199 Ill. 324.

TRANSFER OR FRANCHISE.

Can our company lawfully sell its franchise and will the purchaser get all the privileges we have? W. P.

THE Federal Courts all hold that any agreement by a company which is a common carrier, as a telephone company is held to be, to alienate and transfer the privileges granted it by the government is *ultra vires* and void. U. S. Union Pac. R. Company, 160 U. S. 1. Hatch vs. Amer. Union Telephone Company, 9 Abb. N. Cas. (N. Y.) 223.

The courts of Michigan and Wisconsin, however, have held the sale and transfer of a franchise by a telephone company to be valid, the court pointing out that if the right to sell a franchise does not exist, mortgages and bonds executed by the company are valueless. Michigan Telephone Company vs. St. Joseph, 121 Mich. 502. Badger Telephone Companys vs. Telephone Company, 97 N. W. 907. When a franchise is transferred the transferee takes the property subject to all the duties of the vendor. Mahan vs. Mich. Tel. Company, 93 N. W. 629.

CONDUIT UNDER SIDEWALK.

Can people who live along the main street of our city collect damages from us because we put a conduit to contain our wires under the sidewalk? A. Tel. Co.

A CONDUIT for wires laid under the sidewalk has been held by the Supreme Court of Indiana not to be an additional servitude upon the highway and therefore an abutting owner is not entitled to damages Coburn vs. New Teleph. Co., 156 Ind. 90.

SERVICE OF PAPERS OVER TELEPHONE.

IT has been held in York, Pa., that service of legal papers made by an officer over a telephone is null and void. A man was recently brought into court because he failed to appear as a witness in a surety of the peace case. The witness told the judge that he had been notified to appear by a constable who called him up over the telephone. The constable had handed in a bill for mileage in serving the subpœna. The court directed that the bill should not be paid and censured the officer. It would be rather hard for an officer to make oath to a service made by telephone.

JOINT LIABILITY.

AN employee of a fire-alarm company in the discharge of his duty and for the purpose of stretching a wire on a wooden pole belonging to a company, ascended the pole, and in so doing placed his foot upon an iron spike which was in contact with a feed wire of a traction company, and at the same came in contact with a guy wire of the latter company that supported one of its wire poles. He received a heavy current of electricity through his body which caused him to fall to the ground and receive injuries which resulted in his death. His administrator sued both the telephone company and the traction company, claiming that the death of the deceased was caused by the concurring negligence of the two companies and that they were jointly and severally liable for the loss sustained. The two companies insisted that they were improperly joined as defendants because the acts complained of were not joint, although they might be concurrent and related. They pointed out that the negligence of the traction company lay in not preventing an escape of the dangerous current of electricity which it was conveying through the street by its feed wire, and that its duties and liabilities were greater than those of the telephone company to see that its pole was not made dangerous.

The duties complained of against the traction company were its failure to properly insulate the feed wire, its failure to provide the guy wire with the circuit breaker, its failure to prevent contact of the guy wire with the pole of the telephone company and to prevent the displacement of the feed wire and its lodgment on the iron spike above mentioned. The omissions of duty on the part of the telephone company were alleged to be its failure to remove the feed wire from the iron spike and to prevent the contact of the guy wire with the wooden pole. The court held that the omissions of each were concurrent. It therefore decided that there was no misjoinder of parties. Graves vs. City Telegraph Association, 132 Fed. 387.

CHARGES AND COUNTERCHARGES.

A CHARGE of falsifying the city records of Chicago has been brought against Albert G. Wheeler, president of the Tunnel Company, by Edward J. Judd, formerly the attorney for Wheeler and the son of a former ambassador to Germany. Judd declares that acting on the instructions of Mr. Wheeler he paid $100 to City Clerk Ehrhorn for altering the city council proceedings, which were made to read that the city council had acted favorably on the ordinance permitting the telephone company to make alterations in its line and that this change was made by City Clerk Loefler. Wheeler, on the other hand, accused Judd with attempted blackmail and produced a letter purporting to have been written by Judd demanding money as the price of silence.

PROBATE COURT WITHOUT JURISDICTION.

THE recent decision of the Probate Court at Cincinnati, O., giving Independent telephone companies the right to lay conduits in the streets, has been reversed in the Common Pleas Court by Judge Littleford, who declared that the Probate Court could not grant such right if the city was opposed, unless the company owns and operates a telephone exchange, as provided in Section 3471 Revised Statutes.

"Such an exchange this company does not possess," Judge Littleford declared. "Therefore the Probate Court in the case of a disagreement between this company and the city can only direct a mode of use such as the two might have agreed upon.

"A reading of the statutes will show that the city and the company are not given the right to agree upon a mode of laying conduits, but only upon a mode of stringing overhead wires, and the fact that the statutes were passed before conduits were known to science explains the reason why they are provided for by the statutes. Placing wires in subways was first thought of about 1880, and was not put into use until some years later."

The Queen City Telephone Co.'s application has been made a test case to determine the rights of Independent telephone concerns to establish their system in Cincinnati. Three other Independent company applications are now pending in the courts.

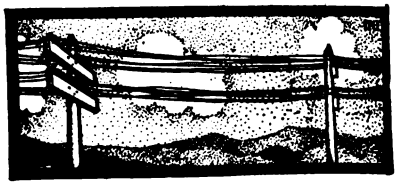
QUERIES

Questions on any subject relating to telephony will be answered on this page.



DEAD ENDING.—(471.)

Will you please illustrate and describe a good substantial method of dead ending wires on the last pole of a line. P. S.

As substantial and good a method as any is to use double arms on the last pole as by their use the liability of a line coming down from a broken arm is reduced to a minimum. This is especially important when the lead may have three, four, or five pairs. The method of dead ending under these conditions is illustrated in Fig. 471. Run the line wire to the insulator at *A* and make one turn; then run to insulator *B* on opposite side of glass

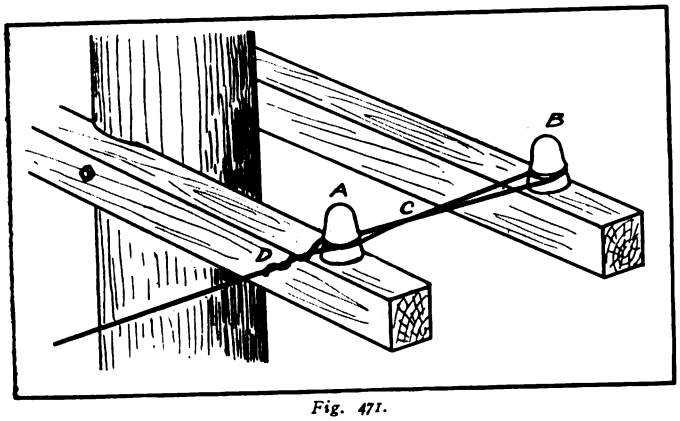


Fig. 471.

and make one turn. Now come back to *A* taking care to cross wire at *C* and make four or five turns on line wire at *D*.

CONDENSER CALCULATIONS.—(472.)

Will you kindly answer the following questions on your query, page 1. How is the value .000,00025 obtained in your recent article on condenser? 2. Why is the value 2π used in computing reactance due to inductance and capacity? S. M. O.

1. The capacity of a condenser same as shown in article of September 10 is given by formula $K = \frac{k\,s}{4\,\pi\,a}$ where

K = capacity in farads,
k = specific inductance capacity,
s = area in square cm.
d = thickness in cm.

Now let

A = area in square inches,
t = thickness in inches,
k = same as above.

Then

$s = A \times 6.452$,
$d = t \times 2.54$,

$$\therefore K = \frac{k \times A \times 6.452}{4 \times 3.1416 \times t} = .2021\ \frac{k\,A}{t}$$

and capacity in m. f. $= 000.000\,2021\ \frac{k\,A}{t}$

instead of .000.000225, as given.

II. In an alternating-current circuit having an inductance L, there is a self-induced E. M. F. set up, the magnitude of which is proportional to L, and the rate of change of current in the circuit. If this current (C) is flowing with a frequency of n cycles per second, the reactive E. M. F. will be $2\ n\ L\ C$ volts. L the co-efficient of self-induction, is the ratio of the number of lines linked with a circuit to the current producing them. ∴ it follows that the C. E. M. F. of self-induction $E = \frac{L\,d\,C}{d\,t}$

Now C is assumed as a sine function of time, having instant value value C, sin $2\ \pi\ n\ t$

Where C_1 = maximum value of C

$$\text{Diff.}\ \frac{d\ C}{d\ t} = 2\ \pi\ n\ C_1 \cos 2\ \pi\ n\ t$$

The virtual values of sine and cos. being equal gives value $E = 2\,\pi n\,L\,C = \omega\ L\,c$, but differing in phase with current by 90°

The value $2\ \pi n$ being the total angle (in radius) passed over by the current in one second, or one cycle is passed over in 2 π seconds. ∴ the angle passed over in any short time $t = 2\ \pi\ n\ t$.

RIGHT AND LEFT GUY.—(473.)

I have frequently heard the terms "right" and "left" guy. How is the right or left hand side of a pole line determined. C. N. L.

The right and left hand sides of a pole line are usually determined from its beginning; thus: A man standing at the point marked *A* in Fig. 473 and looking down the road from pole, one would naturally call all the guys on his right hand side "right" guys and *vice versa* for his left side.

RINGING ON LONG LINES.—(474.)

We have been operating 12, 4-bar, 1600-ohm bridging instruments on a line about 15 miles long. Telephones on last two miles of line ring very weak. Joints and insulation are all right. 1. Can we (by placing telephones of 2,000 or 2,500 ohms, resistance on the last two miles of line) obtain better results, and, if so placed, would they interfere with the 1600 ohm telephones on the rest of the line? 2. Do condensers help a line where only part of the line is equipped with them? R. T. A.

In reply to your first query: As we understand it, you have difficulty in ringing over the end of the long line, and desire to know whether ringing generators wound to 2,000 or 2,500 ohms placed at the end of the line upon which you experience the difficulty, will remedy the same. The trouble is probably due to the fact that your ringing generators are either insufficiently powerful to ring over so long a line, or else that the line is poorly insulated and the current leaks. The use of high-wound bells at

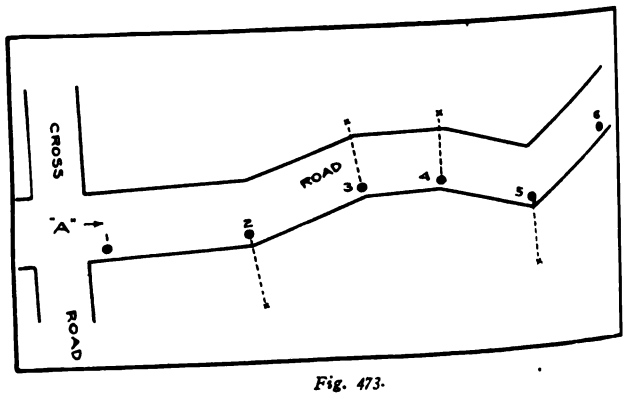

Fig. 473.

the end of the long line may improve matters, but you do not give us sufficient details as to the conditions to enable us to answer you definitely. We think your best plan would be to use a more powerful ringing generator at the exchange.

In reply to your second query: The condenser has nothing to do with the operation of the line at all. It is employed solely to prevent the flow of the battery through the line when the subscriber's receiver is on the hook in lines which are operated from common battery exchanges, and are placed in series with the receivers of magneto instruments to prevent the line being shunted by them when a receiver is off the hook and the line is being rung over.

FOR SALE

Advertisements under this head, $1.00 for 25 words or less for each insertion. Prepaid.

FOR SALE.—I have a telephone proposition which will interest any one of means who cares to investigate. This property is in fine condition; located in excellent field and paying. Write me at once. Box 270, care of AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 270

EXCEPTIONAL offer—I have a three-fourths interest in a telephone stock company owning four good exchanges and 1,000 miles of toll and farmer lines. About 1,000 telephones in operation and sufficient territory for that many more. Stock outstanding amounts to $50,000. Has earned over 30 per cent. in past two years. No competition; $25,000 cash and balance long time; low rate. Address Box 291, AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 291

FOR SALE—500 Tornquist double-pole porcelain base, king of protectors, 50c each; 300 single-pole, 25c each. Address J. S. Maurer, 804 Monadnock Building, Chicago, Ill. 297

WANTED

Advertisements under this head, 25 cents for 25 words or less for each insertion. Prepaid.

WANTED—To meet an investor with capital with a view to developing an automatic telephone which can be made at one-third cost of present automatic systems, also other telephonic devices. Exceptional opportunity. No agents or promoters need apply. Apply Box 272, care AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 272

WANTED—Position as superintendent of a large exchange or manager of a plant, 1,000 telephones or less. Have had ten years' experience in all branches of the business. At present am superintendent of an exchange in a city of 175,000 population. Open January 1st to any company that wants a hustler. Address Box 286, AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 286

WANTED—Position as manager with a first-class company looking for a hustler. Experienced particularly in toll and long distance work, including clearing house methods, and line construction. Familiar with every detail of telephone work. Executive ability; excellent references. Address Box 285, care THE AMERICAN TELEPHONE JOURNAL, New York. 285

WANTED—Man experienced in underground conduit and cable work; office and outside workman who can run levels preferred. Give references and salary expected. Chance for advancement by large telephone company. Address Box 298, AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 298

WANTED—Telephone salesman. One familiar with exchange material as well as interior systems. Address Box 299, care AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 299

WANTED—Telephone salesman who has had experience in handling intercommunicating and private branch exchange apparatus. Address Box 296, AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York City. 296

POSITION wanted by switchboard expert, with twelve years' experience. References given. Address Box 300, AMERICAN TELEPHONE JOURNAL, 116 Nassau street, New York. 300

SOME NEW FEATURES IN SWITCHBOARD DESIGN.

THE telephone industry is one which has never stood still in its development. New ideas, new plans have been and are being constantly developed, which all lead to the ultimate perfection of the mechanical and electrical details of the apparatus. Although magneto switchboards have been in use for a great many years, and numberless improvements have been made since the first boards were manufactured, the subject has never been dropped and new ideas in their construction and operation are being presented continually. Almost every little change has been a forward step, but quite a leap toward simplicity of construction was made when the Monarch Telephone Mfg. Co., of Chicago, designed the self-restoring drop and jack illustrated on this page. One very noticeable characteristic of all Monarch apparatus is the simple ideas of construction and the ease with which any part of the whole can be removed or placed in a position for ready inspection.

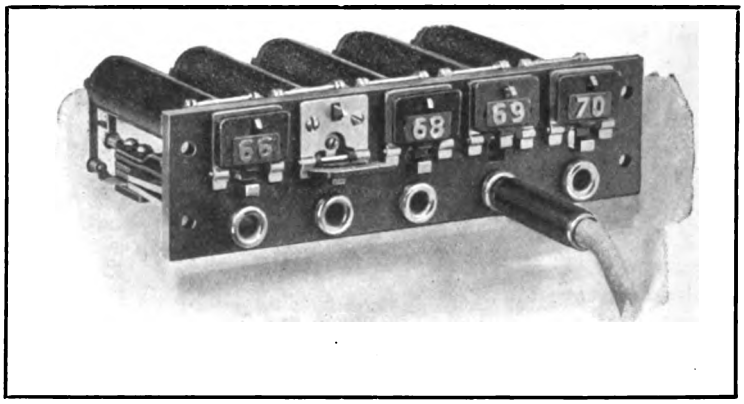

Fig. 1. Monarch Self-Restoring Drop and Jack, Showing Features of Mechanical Construction.

Practically all telephone men agree that the removable shelf feature of the Monarch compact telephone is an advantage, and undoubtedly the drop construction will meet with as universal approval. What exchange man has not had trouble removing a coil from a drop? The old method of construction made it necessary to entirely spoil the adjustment of the armature whenever a coil was taken out. The new method, as shown herewith, requires no such waste of time. By placing the armature on the front of the drop shell, the adjustment can be made permanent.

The coil is removed from the back of the shell, and therefore does not in any way change the armature adjustment. It will be seen that connectors extend from the jack springs to the drop coil. These connectors are slotted at the upper ends so that the slots may be fitted under the screws in the head of the coil. By loosening these screws the connectors can be turned down and the coil removed. The second cut shows this feature. In the head of the coil is a pin which fits into a right-angle groove in the shell so as to make a lock to securely hold the coil when in place. The coil terminals are soldered to small brass lugs, into which the connector screws fit. A first-class connection is thus secured, and there is no danger of breaking the fine wire which constitutes the coil winding.

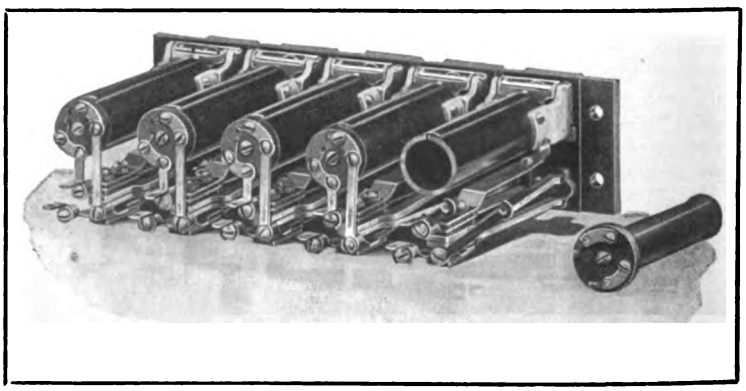

Fig. 2. Monarch Self-Restoring Drop and Jack, Showing Removable Features of Drop Coil and Mounting.

Another advantage of mounting the armature in front of the coil is the increased sensitiveness. The shutter hook is short, and a smaller amount of current will operate the drop than by the use of a long hook extending from the back of the coil. The leverage is greatly reduced, and therefore less power is required. This point is especially valuable for bridging drops on long and heavily loaded lines.

The armature is made of Norway iron, and is carefully annealed to obviate any trouble from residual magnetism. The coils are wound with silk-covered magnet wire to their marked resistance. As all parts are made from especially constructed tools and dies, a coil from any Monarch drop will exactly fit any other Monarch drop.

The jack construction shows a distinct departure from old ideas. The mounting for the springs is formed up from heavy brass strips which are riveted to a brass collar on the mounting plate. An extremely rigid mounting is thus secured. Another good feature is that there is no place for dust to accumulate. A spring is provided for both tip and sleeve contacts so the connections do not depend on the jack sleeve. Platinum contacts are used throughout, and the springs are of German silver. All insulators and bushings are hard rubber, and terminals are provided for either screw or soldered connections.

An extremely simple and positive restoring device is used. An extra spring having no electrical connections whatever with the rest of the jack is placed above the regular jack springs, and is fastened by means of a rubber insulated pin to the sleeve contact spring. The end of the restoring spring extends through the mounting plate and is bent upward in the form of a right angle. A plug being inserted in a jack, the tip of the plug passes the sleeve contact spring and raises it. This action also raises the restoring spring, and the end or angle part of the spring engages the drop shutter and restores it. The springs and other parts of the jack are made of sufficiently heavy stock to preclude any trouble from weak action. The action is just the opposite—quick and sure. The fact that the restoring spring is operated by the sleeve contact which, in turn, is raised by the tip of the plug, causes the drop to be restored before the plug is more than one-third of the way in. This takes the shutter out of the way of the operator's thumb.

The drops and jacks are entirely insulated from each other, and also from the mounting strip. It is therefore impossible to get any cross-talk, and improbable that a whole strip of drops will ever be burned out by lightning. In fact, the drops and jacks are separate units mounted on 1 3/16" centers on steel mounting strips 1¼" wide by 6¼" long. The front of the drop and jack

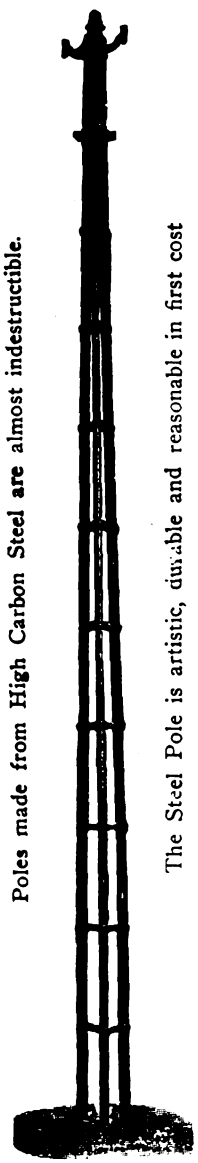
The Open-Wireless Telephone Plant

is an all-cable plant; that is, it has no open wire (bare wire) or cross arms, and when supported on steel poles

DEPRECIATION IS ALMOST ELIMINATED; MAINTENANCE REDUCED TO A MINIMUM



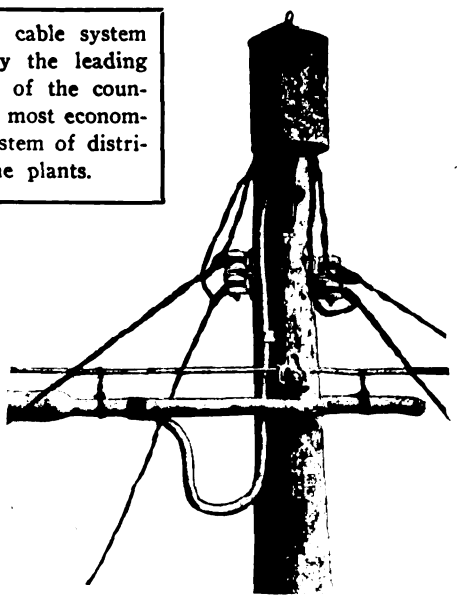
POLE OF THE FUTURE

Poles made from High Carbon Steel are almost indestructible.

The Steel Pole is artistic, durable and reasonable in first cost

No poles to rot.
No cross arms to rot.
No glass insulators to break.
No crossed wires to interfere with service.
Trees do not interfere.
Sleet storms lose their terror.
No unsightly cross arms and wires on the streets.
No bare wires to break and fall on electric light wire and kill someone passing by.

The multiple tap cable system is acknowledged by the leading telephone engineers of the country to be by far the most economical and durable system of distribution for telephone plants.



THE SYSTEM OF THE FUTURE

The undersigned is a pioneer in multiple cable distribution and makes a specialty of

Planning Cable Layouts
Multiple Cable Distribution
Equipping for Party Lines
Rate Raising, Etc., Etc.
Plans, Specifications and Supervision of Installation of Complete Telephone Plants

WILL GUARANTEE TO INCREASE THE DIVIDENDS IN 99 TELEPHONE PLANTS OUT OF EVERY 100

Engineering, constructing and putting plants on a dividend-paying basis a specialty.

There are many serious mistakes made in the selection of apparatus, construction and maintenance of telephone plants due to lack of experience.

There are many leak holes in a telephone plant unless properly watched.

With proper co-operation on part of owners of telephone plants I will guarantee to make any Telephone Plant pay dividends or increase your present earnings. Can refer you to a number of telephone plants where I have saved thousands of dollars in first cost of the plant, increased the earnings, improved the service, decreased the operating expenses by installing proper apparatus in the proper way and properly organizing the working force. Can furnish expert engineer, wire chief, auditor, solicitor, chief operator, each a specialist in his line.

strip is neat and very sensible. The mounting plate is given a genuine Bauer-Barrf finish, which leaves it a dead black, which is much easier to the eye than a polished surface, and so far as lasting qualities are concerned it cannot be surpassed. The jack sleeves are nickel plated, but not polished. This makes it easier for an operator to distinguish each separate jack than by the use of glaring white jack sleeves.

The drop shutters are given a Bauer-Barff finish, and are equipped with raised number plates. The shutter hooks and drop faces are nickel plated, but not polished. The complete strip has a neat appearance, and is very satisfying to the eye. Durability has been considered before showiness, but nevertheless a handsome effect has been produced. Although the Monarch switchboard has been advertised very little up to this time, boards with an equipment of over 2,000 drops have been sold. The Monarch Company attributes this rather extraordinary success to two facts: The absolute confidence Monarch customers place in all products of the Monarch Company, and the substantial and simple construction of the apparatus.

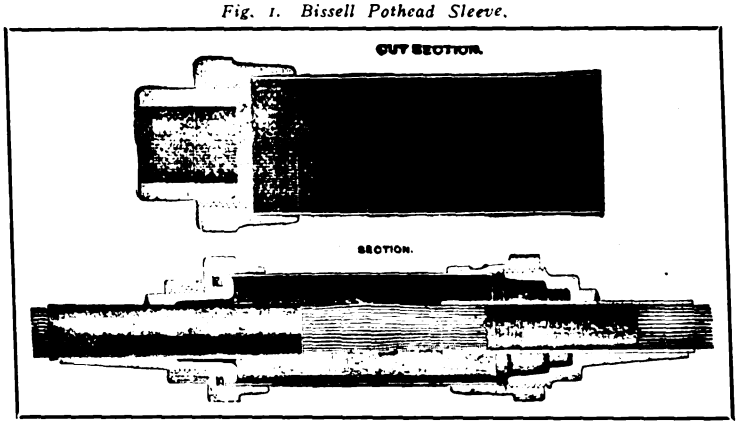

Fig. 2. Bissell Sleeve—Straight Away.

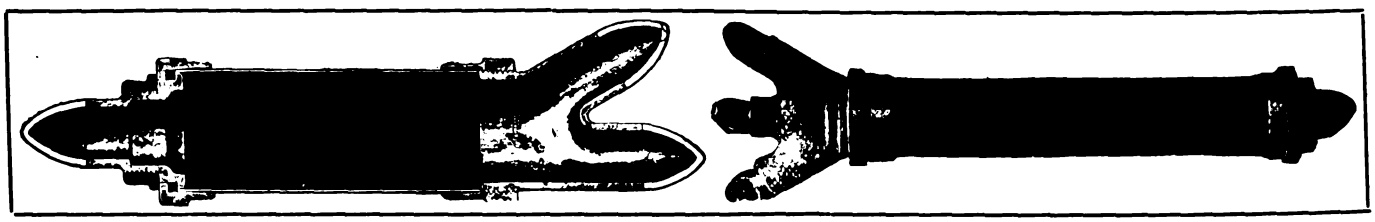

Fig. 3. Bissell Y Branch.

Fig. 4. Bissell Three-Way Branch.

NOVELTY IN POTHEADS AND CABLE SLEEVES.

LONG experience has proven the pothead to be the most efficient and most economical method of terminating cables. In the past it has always required particularly skilled labor to insure the pothead being made in such manner as to be absolutely water tight. This is necessary to preserve the insulation of the cable from subsequent deterioration.

THE F. BISSELL COMPANY, of Toledo, O., have a device on the market which is termed a slidable pothead. Its object is to make potheads more accurately, and with less probability of future deterioration of the cable. The general design of this invention is shown in Figure 1, from which it appears that the pothead consists of a sleeve which is soldered into one-half of a union. By means of a screw thread this sleeve engages the collar, which is secured by soldering to the cable. With this invention the operation of making a pothead is extremely simple.

In the first place, by means of a wrench the sleeve is unscrewed from the collar. It is then taken away and the lead is stripped from the cable for the proper distance. The collar, *K*, is next soldered by means of an ordinary soldering iron to the end of the lead sheath. The sleeve is then slipped over the cable and down beyond the collar. The cable wires are then fanned out and arranged in any desired manner. The sleeve is then returned to its position, and secured in place upon the collar. And finally the cable ends, after being arranged inside of the sleeve, are insulated by pouring the sleeve full of any desired cable compound, such as Chatterton's or any other make. This completes the pothead, which it is evident can be made with the exercise of but a small amount of skill. Figure 2 is an illustration of a soldering device, which is designed for the purpose of making splices in cables. A slight inspection of the figure shows that it is in principle similar to that of Figure 1, except that there are two collars, *A* and *B*, one of which is soldered on to the lead of one cable while the other is similarly attached to the lead of the other. The sleeve is unscrewed and slipped over the sheath of one cable, then the wires are fanned and spliced in the ordinary manner, and subsequently the sleeve is replaced upon the union and the joint filled with compound in the ordinary manner.

An arrangement is shown in Figures 3 and 4 whereby a Y splice may be made by means of the same device. They are self-

explanatory. The ease and economy whereby cable work may be performed by means of this invention are self-evident, and while the devices themselves are somewhat more expensive than the materials ordinarily required in making potheads, they amply recoup themselves in the greater economy of labor. The F. Bissell Co. is also marketing some devices which are shown in Figures 5 and 6 for securing potheads in place either on the walls of buildings or to the poles or other appliance upon which the cables terminate. The method of using these is sufficiently obvious from the illustration to render further description unnecessary.

The company has just issued a leaflet describing these devices and also its "Security" paper insulators for cables, American wire joints, wrenches, cable compound, shave hooks for scraping lead sleeve, boxwood dresser for shaping lead sleeves, boxwood turn pin for expanding ends of lead sleeves, and a few of the many varieties of wires and cables it carries in stock. This circular is arranged in bulletin form, with holes punched for binding, and is known as Supplement No. 1 to Bulletin No. 33. A copy will be cheerfully mailed to anyone asking for it.

AN INEXPENSIVE TOLL TIME STAMP.

FOR some time operating telephone companies have been looking for a self-contained time stamp which is thoroughly reliable, and also one that prints a small, clear and easily readable record. Mr. Edw. P. Baird, realizing the field open for such a stamp, has invented and put upon the market the Baird Rapid-Lever Self-Contained Time Stamp. This stamp has won for itself many admirers among telephone operators. A glance at the illustration (Fig. 1) will show that the stamp is made in a very substantial way. Experience has proven that it will stand up under the most severe usage. Further than that, the operator has no trouble in reading the record, a sample of which is shown in Fig 2, made by the stamp at first glance. Then again, the stamp can be sunk into a switchboard, making it possible to handle toll tickets very rapidly.

Fig. 1. Baird Time Stamp.

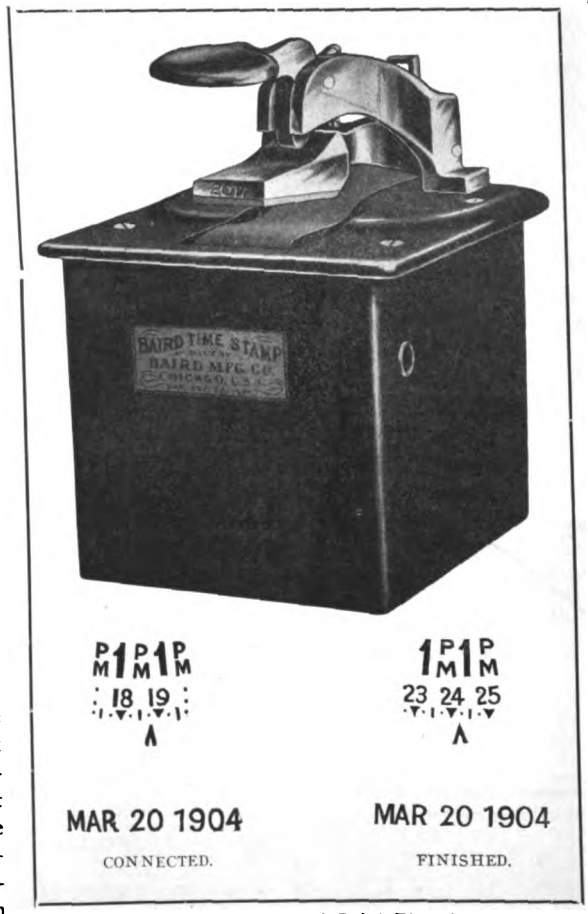

Fig. 2. Impressions of Baird Time Stamp.

The Seth Thomas Co. has made a special movement for use in this clock so the jar incident to making the record will not be imparted to the movement and put it out of order. The printing dials revolve on polished, case hardened bearings, and the construction is such that the force of the imprint does not reach the bearings. The automatic ribbon reel takes up ribbon at each action of the lever, so that the ribbon is not worn out quickly.

The Baird Time Stamp is guaranteed against all structural defects, and any part which proves defective will be replaced free of charge. The Baird Manufacturing Company, 4 Michigan street, would be pleased to answer any further questions regarding the stamp, and send descriptive literature on request.

NEW MANUFACTURING COMPANY.

THE newest concern in the market for supplying switchboards, telephones and telephone apparatus to the Independent trade is known as the KUSEL & KUSEL AUTOMATIC SWITCHBOARD & TELEPHONE MANUFACTURING COMPANY, with main offices in the Monadnock Building, Chicago, Ill. The company announces that it will make a specialty of Clark automatic and manual switchboard apparatus.

The principal stockholders in the new concern are Messrs. I. J. and H. J. Kusel, who have been associated with the Eureka Electric Company for the past eight years. They have severed their connection with the Eureka Company to establish the new concern. They are both well known in the Independent field.

A new catalogue and descriptive matter in bulletin form of the apparatus manufactured by the KUSEL & KUSEL AUTOMATIC SWITCHBOARD & TELEPHONE MANUFACTURING COMPANY will be issued in about ten days, and will be sent to any one interested.

THE KNOX-DICKEY TELEPHONE MANUFACTURING CO., Portsmouth, O., has recently entered the market with a selective party system that has a number of points of interest worthy of the investigation of all exchange managers. A very valuable feature of the devise is that it operates irrespective of frequency or voltage, thus allowing any type of hand or machine generator to be used. The mechanical details have been reduced to the simplest possible point eliminating brased springs and other devices used to determine the signals of the bells. By the aid of an auxiliary battery of about sixty cells, thirty for each side of the line, selective signaling for four parties can be accomplished. There are no relays to get out of adjustment. Bells are rung with alternating current and do not chatter, and the simplicity of the system is such as to enable it to be easily understood by any parties at all acquainted with telephone operation.

THE CENTURY TELEPHONE CONSTRUCTION CO., of Buffalo, N. Y., is completing the construction of the long-distance line from Buffalo to Jamestown, N. Y., for the Inter-Ocean Telephone and Telegraph Company. The line is a standard trunk line with full copper metallic circuits.

MORGAN AND WRIGHT, Chicago, wish to draw the attention of the telephone trade to its tape. Tape is one of the most essential adjuncts to a telephone system, and consequently it should be of the best possible manufacture, as quite often the operation of a line depends upon it. The Morgan and Wright tape possesses all the advantages of other grades in a superlative quality. From an insulation standpoint it is very high in resistance and besides is very uniform. It will not dry out and possesses exceptional adhesive qualities. Samples and prices for the asking.

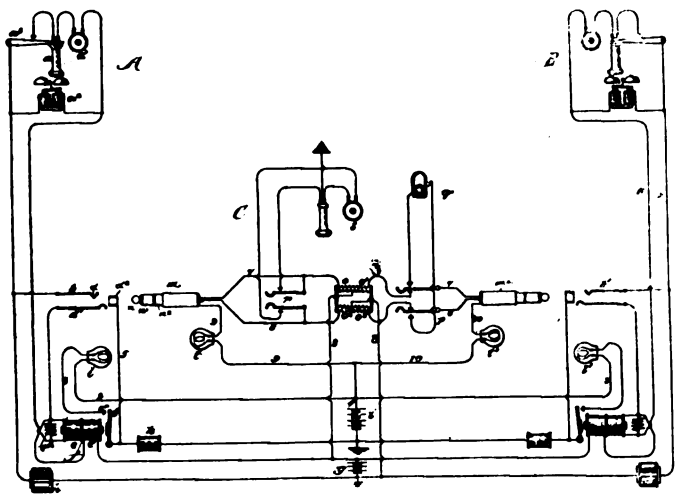
TELEPHONE PATENTS

COMMON BATTERY SWITCHBOARD CIRCUIT.

F. R. McBerty, of Evanston, Ill., patents (No. 774,332) and assigns to the Western Electric Co., of Chicago, Ill., an improved common battery switchboard circuit. The object of this invention is to provide an improved circuit for common battery switchboards, and is an improvement upon a former patent (No. 680,879) granted to the same inventor. The operation of this system is as follows:

When the subscriber *A* removes the receiver, circuit is closed from battery *g* through windings *e'* and *e* of the relay *f*, thence



over the line conductors *1* and *2* and through the impedance coil *h* back to battery. The relay is excited and closes the local circuit through the conductor *4*, resistance coil *k*, contacts *e'* and *e3* of relay lamp *1* and conductor *3* to battery. The insertion of plug *m* into the jack *b* provides a low resistance path through the windings *o* and *o2* of the repeating coil, and the winding *o* becomes a shunt about the coil *e'* of the relay. Also branch *9*, containing the supervisory lamp *t*, is closed and becomes a shunt to the local circuit *3 4*, including the line lamp *1* and the resistance coil *k*. Hence the insertion of the plug extinguishes the line lamp, while at the same time the supervisory lamp remains unlighted. The operator takes the order in the usual manner with the listening key *r* and rings the called subscriber with the key *p*. When the connecting plug *m'* is inserted in the jack *b'* of the called subscriber, the circuits are similar to the ones already traced, but since the relay of the line is not excited, conductor *3* is interrupted, signal lamp *1'* is dark, while the supervisory lamp *t'* is lighted. When the subscriber removes the receiver the relay is excited, closes conductor *3* and extinguishes signal *t'*. When either or both receivers are replaced the corresponding relay becomes inert and the entire current is diverted through the corresponding signal.

IMPROVED SUPPORT FOR TELEPHONE RECEIVERS.

F. W. St. John, of Coshocton, Ohio, patents (No. 771,946) an improved support for telephone receivers. The inventor provides an arm upon one end of which the receiver is attached by means of a spring fork. This arm is pivoted so that it may be rotated in a vertical plane and thus adjusting the ear of the person using the instrument.

PARTY LINE TELEPHONE SYSTEM.

William R. Whitehorne, of Bethlehem, Pa., patents (No. 775,201) party line telephone system. The object of this is to provide a party line telephone system so that the central office can call any subscriber without signaling any other one, and that the ringing of the bell may be accomplished simply by the inserting of the plug, without any further action on the part of the operator. The circuit is shown in Fig. 1 and substation apparatus in Fig. 2.

The chief feature of the invention is the employment of differential magnets at the substation. If the subscriber, say *D*, removes his receiver from hook *14*, and hook will rise, carrying bar *2* causing arm *15* to be interposed between armature *16* and magnet *a*, opening the circuit of main line *A*. Immediately afterwards switch *m* is momentarily closed and then opened by hook *14*, thus momentarily connecting the local battery *f* across the mains *A* and *C*, energizing the circuit breaker *j*. The winding of this circuit breaker and the connection of the battery *f* are such that armature j^2 is attracted, releasing the *j'* signal, and also opening the switch of which *j'* is a part, and opening the short circuits of the mains *A* and *C*. This movement can also display the busy signal. The end of hook *14* connects the terminals of switch *3* to complete circuit of transmitter *9*, and permits bar *2* to engage wth terminal *17*, completing the circuit of receiver to main *A*. The operator plugs in, sending current from battery *n* through main *C* to ground.

As all of the windings of a^3 are in series with each other and the main *C*, all the magnets *a*, *a'*, a^2, etc., are energized, and all, with the exception of *a*, attract their armatures; *a's* armature cannot move because of the interposition of arm *15* between its arm and core. Where any armature is moved, the signal *6* is operated by local battery *f*, bar *1* being moved to contact with terminal *18*. Resistances *K*, K^3 and K^4 are so proportioned to the windings on the magnets *a*, *a'*, etc., that the current from

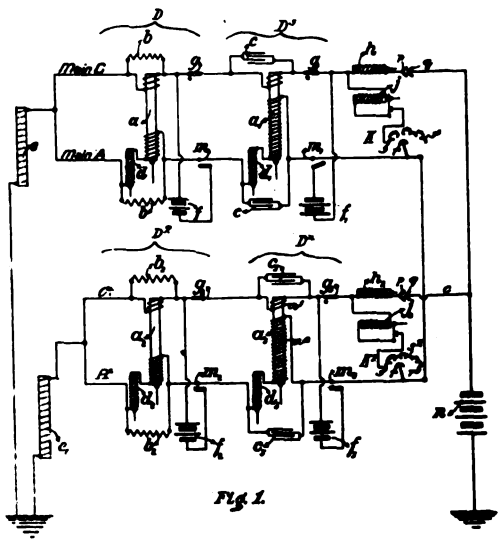


Fig. 1.

n divides between the mains *A'* and *C'* so that the field produced by one of the windings on the magnet a^2 or a^4 will neutralize that produced by the second winding upon the said magnet; but since the ratio of the windings upon a^2 is different from that of a^3, the armature of the magnet will move. The current through *A'* will energize the bell controlling magnets *d*, and will close the switches *8*. The closing of said switches will have no effect except on the instrument it is desired to call, namely a^3, since the armature *16* is the only one that is in such a position as to complete the local circuit of battery *f* to bell *B* bar *1*, consequently bell *B* is rung continuously until the receiver is removed.

THE WEEK'S MESSAGES

FINANCIAL.

BRAYVILLE, ILL.—Mr. W. E. Westfall, manager of the Independent Telephone System, is arranging to organize a stock company with a cash capital of $4,000, and to erect a modern city exchange.

EDMORE, O.—At the annual meeting of the Ottawa County Telephone Co., the usual dividend of 3½ per cent. was declared.

CLEVELAND, O.—The October statement of earnings of the United States Telephone Co. shows an increase, gross, of 6 per cent and a net increase of 9.6 per cent. over the similar period last year.

NORTHFIELD, VT.—At a recent meeting of the Northfield Telephone Co. a reorganization of the company's stock was effected, and it is reported that about 2,200 shares will be issued.

GREEN BAY, WIS.—The Valley Telephone and Telegraph Co., of Green Bay, have increased their capital stock from $200,000 to $250,000.

FRANCHISES.

FRESNO, CAL.—The Home Telephone & Telegraph Co. will apply to the City Council for a franchise.

BICKNELL, IND.—The county commissioners have granted a franchise to a new telephone organization covering the right to use the highways of Vigo, Widner and Washington townships for erecting poles and stringing wires.

EVANSVILLE, IND.—The District Telephone Co. has asked the board of public works for permission to erect a new pole line two miles in length.

PARKERSBURG, IA.—The Farmers' Mutual Telephone Co. has started a petition for a franchise in this village.

ERSKINE, MINN.—A. F. Cronquist, J. A. Lang and E. E. Payne have been granted a twenty-year franchise by the city council.

NEW ULM, MINN.—The Blue Earth Telephone Co. has been granted a franchise for ten years, for which it will pay $1,500.

NEW COMPANY NOTES.

OZARK, ARK.—The Western Telephone Co., of Ozark, has been incorporated with a capital stock of $100,000 to operate, buy and sell telephone systems. L. F. Maxey, treasurer; W. H. Fulker, L. D. Huggins and others directors.

LOS ANGELES, CAL.—The Richardson Construction Co. has been organized with a capital stock of $500,000 for the purpose of undertaking telephone construction in various parts of Mexico. The principal organizers are: Davis Richardson and L. R. Richardson, of this city.

ELBERT, COLO.—The Elbert Mutual Telephone Co. has been incorporated with the following officers: President, C. A. Whittier; vice-president, R. Larson; treasurer, H. D. Duvall; secretary, Mrs. M. E. Merriam; manager, W. S. Epler.

CLINTON, IA.—The Tri-City Telephone Co. (sometimes erroneously called the Twin-City) has been incorporated with a capital stock of $600,000 and bonds $400,000. This company operates exchanges in Clinton and Lyons, Iowa; and Fulton, Ill. The officers are: President, and general manager, Allen G. Hawley, Clinton, Ill.; vice-president, D. F. Higgins; secretary and treasurer, C. B. Cheadle, of Joliet, Ill.

HASKELL, I. T.—The Haskell Telephone Co. has been incorporated with a capital stock of $10,000. The incorporators are J. C. Scully and C. E. Henson, of Haskell, I. T.; W. J. Criswell, of Wileyville, W. Va.; and George S. Whidden and Earl G. Hopkins, of Boynton, I. T.

LOUISVILLE, KY.—The Kenyon Construction Co., with offices at 405 Urban Building, Louisville, has been incrporated to build and operate telephone exchanges in Kentucky and adjoining States.

MEDFORD, MINN.—The Straight River Telephone Co. has been organized among business men at Medford, who will open an exchange at that place and connect with the Northwestern. The line will be about eight miles long.

WOOD LAKE, MINN.—The Wood Lake Rural Telephone Co. has been incorporated with a capital of $30,000 by J. W. Griffith and others.

AUBURN, MISS.—The Auburn Telephone Co. has been incorporated with a capital stock of 35,000 by B. H. Ramsey, E. R. Conklin and F. W. Kelly.

BELLEVILLE, MO.—The Rural Telephone & Telegraph Co. has been incorporated with a capital stock of $2,500 by L. D. Turner, A. Hinke and G. W. Detharding.

NEW YORK, N. Y.—The Interborough Telephone & Telegraph Co. will be incorporated with a capital stock of $100,000 to construct long distance lines between Philadelphia and New York and Montreal and New York. The directors are H. S. Gould, Charles A. McCready, of New York, and others.

RINARD MILLS, O.—The Pryor-Bode Telephone Co. has been incorporated with a capital stock of $5,000 by J. H. Pryor, M. Bever, G. A. Bodea and others.

PIERRE, S. D.—The South Dakota Telephone Co. has been incorproated with a capital stock of $100,000. The incorporators are: A. Ewart, E. P. Farr and W. S. Rowe, of Pierre; and G. E. Sumner and C. L. Millette, of Fort Pierre.

EGLON, W. VA.—The Eglon Mutual Telephone Co. has been incorporated with a capital stock of $5,000.

HARDY, W. VA.—The Hardy Mutual Telephone Co., of Hardy, W. Va., has been incorporated with a capital stock of $5,000 to operate a telephone system in various towns along the public roads of the State. The incorporators are J. H. Park, A. D. Walker, R. J. Wilkins and J. W. F. Combs of Needmore; and B. E. Brill, of Fabins.

COMBINATIONS.

MONROE, GA.—The Monroe Telephone Co. will consolidate with the Monroe Telephone Exchange Co., the Walton Telephone & Telegraph Co., and the Monroe and Campton Telephone & Telegraph Co.

BLOUNTSVILLE, IND.—The Cambridge City Telephone Co. has bought the plant of the Blountsville Telephone Co. Mr. Lamb is president of the new company.

BLUE RAPIDS, KAN.—The Greenleaf Telephone Co. has been sold to the Blue Rapids Telephone Co. for $12,200.

EDMONTON, MANITOBA.—The city council has purchased the Edmonton District Telephone Co.'s line for $17,000.

FALL RIVER, MASS.—It is reported that a controlling interest in the Fall River Automatic Telephone Co. has been purchased by John T. Swift and others. The officers of the company are: E. B. Jennings, president; B. D. Davol, treasurer; and E. B. Jennings, B. D. Davol, Quinlan Leary, R. F. Haffenreefer Jr., M. Feeney, A. P. Mathewson, Dr. R. J. Thompson, M. Sweeney and Vinton A. Sears, of Boston, directors.

ST. PETER, MINN.—The stockholders of the Nicolett County Telephone & Telegraph Co. have voted to purchase the St. Peter Telephone system from James Bennett for $35,000. The deal will be closed on December 15th.

FREMONT, NEB.—The Trumbull Exchange is to become a part of the Hamilton County Farmers' Telephone Association on December 1, 1904.

NEW ROCKFORD, N. D.—Henry Wilson, of Wimbledon, has closed a deal whereby he now owns the telephone exchange at this place.

ELECTIONS.

MORO, ILL.—The Moro telephone line No. 1, at its annual meeting, elected Z. E. Bivens, president; John Unterbrink, vice-president; Smith Dorsey, secretary; F. C. Zoelzer, treasurer; C. E. Cooper, electrician; W. D. Kuethe, director.

ST. JOSEPH, ILL.—The following officers have been elected by the recently incorporated St. Joseph Telephone Co.: President, O. C. Boggs; vice-president, T. J. Wardin; treasurer, N. G. Glascarth; manager, J. O. Henderson.

CONCORD, IA.—G. W. Mason, of Kanawha, has been elected president of the Hancock County Rural Telephone Co. to succeed E. C. Abbey.

WINDSOR, ONT.—The Ontario Independent Telephone Co., at a recent meeting, organized with the following officers: President, John H. Connelly; vice-president, James H. McRae; treasurer, F. J. Lawrence; secretary, A. D. Prosser; general manager, C. W. Taylor; assistant general manager, P. T. Shesley. The directorate consists of the foregoing officers and J. R. Brooks and Mayor Brault, of Amherstburg. The company will install an automatic exchange system and will commence work immediately on its lines throughout Essex county, beginning at Amherstburg. Over 400 subscribers have already been secured.

MISCELLANEOUS.

HUNTSVILLE, ALA.—Another co-operative telephone company is being formed by Madison county farmers and the proposed system is planned to connect Wooley Springs, Jeff, Cluttsville and other communities in the nohthwestern part of the county with the Huntsville exchange.

MILFORD, IND.—The Royal Telephone Co. has recently bought two new switchboards for its exchange in this city.

NEWCASTLE, IND.—The Independent Telephone Co. recently sustained a loss by fire of $2,000 in cables.

DES MOINES, IA.—The Mutual Telephone Co. expects to move into its new exchange in the near future.

ASHLAND, NEB.—H. H. Herndon, of the Ashland Telephone Co., has sold his stock to H. A. and E. A. Wiggenhorn, Jr., and C. H. Folsom. The latter will succeed Mr. Herndon as president and general manager.

COLUMBUS, O.—The Montgomery County Telephone Co. is soliciting stock to operate the exchanges in Dayton and a number of neighboring towns.

COLUMBUS, O.—The executive committee of the Ohio Independent Telephone Association met here recently to devise plans for a more compact organization of the independent telephone companies of the State. Those present at the meeting were: J. B. Hoge, of Cleveland; Dwight E.

Sapp, of Mt. Vernon; E. L. Barber, of Toledo; and Cyrus Huling and Frank L. Beam, of Columbus.

HOLLIDAYSBURG, PA.—A farmers' telephone company, with a capital of $10,000, is being organized at this point.

MONTROSE, PA.—The Montrose Telephone & Telegraph Co. has its Tunkhannock line with the Tunkhannock & Wyoming Valley Telephone Co. completed, and is now able to give service to distant points, such as Scranton, Wilkesbarre, Philadelphia, Towanda, Elmira, etc., with their intermediate points and connections.

SPRINGFIELD, VT.—The Springfield Local Telephone Co. now has 200 subscribers and is constantly growing.

UNDERGROUND.

CITY OF MEXICO, MEX.—It is expected that the Mexican Government will soon act on the plans submitted by the Mexican Telephone Co. for the placing of its wires underground, in the central portions of the city.

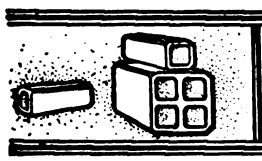
PERSONAL.

H. C. FUHE has been appointed assistant superintendent of the Ohio Valley Telephone Co., at Bellaire, W. Va.

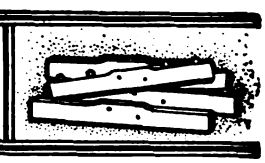
A. J. KENEDY has been appointed supervising engineer for the Fulton Telephone Co., at Fulton, N. Y.

D. H. MULLENIX has been appointed to an important position in the traffic department of the Southern Bell Telephone Co., at Atlanta, Ga.

F. R. WAKEFIELD has been appointed manager for the Michigan State Telephone Co., at Lapeer.



New Construction in the Field



CANTON, ILL.—The Canton Home Telephone Co. will commence the construction of a line to Fiatt as soon as the material can be placed upon the ground. Connection will be made at Fiatt with lines running to all parts of the county, and also to the principal cities in the adjoining counties, such as Galesburg, Peoria, Havana and other places.

PORTLAND, IND.—The Home Telephone Co. is extending its system of rural lines.

CONVERSE, IND.—The Converse Telephone Co. is busy erecting a new cable line.

PRINCETON, IND.—The Independent telephone company has made arrangements to build a new exchange in this city next spring.

HUDSON, IA.—The Hudson Mutual Telephone Co. is constructing a new line south of this town.

TOPEKA, KAN.—The Independent Telephone Co. of this city is contemplating extensive improvements.

LIBERTY, ME.—The China Telephone Co. will extend its lines to Liberty and Coopers' Mills.

SKOWHEGAN, ME.—The Farmers' Co-operative Telephone Co. is building its lines into the eastern part of this village.

ELKTON, MD.—The Diamond State Telephone Co. has reconstructed its lines between this point and Cherry Hill.

YUCATAN, MEX.—All the telephone lines in the State of Yucatan are to be thoroughly repaired.

ONTONAGON, MICH.—A project is on foot for the construction of a telephone line connecting this place on the north side of the county. It is proposed to build a line from Ontonagon to the Norwich mine, and thence to Matchwood, Bergland, Ewen, Bruces' Crossing and Trout Creek. The distance involved is between forty and fifty miles and it is figured that the line could be built for about $2,000. The Ontonagon County Telephone Co. connects the principal towns in this vicinity and some working agreement could be made with which to handle messages from the newly connected towns and villages.

DULUTH, MINN.—The Mesaba Telephone Co. is building a new line which will carry eighteen wires. Forty-foot poles are being used.

FOSSTON, MINN.—Fosston's local telephone system has completed a new branch line from this point to Winger, a town on the new Soo line southwest of here.

HENDERSON, MINN.—The Henderson Telephone Co. is building a new line to Green Isle.

SACRED HEART, MINN.—Carl Anderson will install a local telephone exchange.

SHAKOPEE, MINN.—Work on the Eden Prairie and Bloomington country lines is rapidly nearing completion.

VESTA, MINN.—The Rural Telephone Co. intend to extend their line from Seaforth to this place.

WRIGHTSTOWN, MINN.—The H. & W. Telephone Co. are rebuilding the line into Parkers Prairie.

MISSOULA, MONT.—The Big Blackfoot Telephone Co. has completed a line from Drummond to Orando via Helmville.

SEWARD, NEB.—The Lincoln Independent Telephone Co. will extend two copper circuits from this village to Lincoln.

FULTON, N. Y.—The Fulton Telephone Co. has decided to enlarge and improve its present system in this city to meet increasing demands by installing a new line of cables throughout, new and larger switchboard, new automatic telephones and many other minor changes.

NEW YORK, N. Y.—The Lehigh Valley Railroad is building a telephone system along its lines. A circuit has been constructed to Wilkesbarre and will be continued to Sayre.

UNION, O.—The Putnam Telephone Co. has constructed a farmers' line on the road between Sugar Creek and Union townships, connecting with the main line at Columbus Grove.

UTICA, O.—The Utica-Homer Telephone Co. and the Newark Company are jointly constructing an additional circuit from Utica to Newark, to avoid the delays in toll business that now occur by the lines being busy.

MANGUM, OKLA.—The Willow Telephone Co. is enlarging its system. They expect eventually to extend their line to Delhi and connect with the independent line there.

OKLAHOMA, OKLA.—The Pioneer Telephone Co. will shortly extend its lines to Muskogee and other points in the Territory.

BENTLEYVILLE, PA.—The Maple Creek Telephone Co. will build a line into this village.

EUGENE, ORE.—Wires for the Eugene-Florence telephone line have been strung between Eugene and Elmira, a distance of fifteen miles. The remaining sixty-five miles will be strung as soon as the work of setting the poles is completed.

BIRDSBORO, PA.—The Conestoga Telegraph & Telephone Co. are vigorously prosecuting the work of erecting poles and wires throughout this town.

DUBOIS, PA.—The Summerville Telephotne Co. will reconstruct its system and build additional lines in the near future.

WELLSBORO, PA.—The Citizens' Mutual Telephone Co. is building a line from Tioga to connect at Painter Run with its line to Elmira and Mansfield.

WILKES-BARRE, PA.—The Peoples Telephone Co. expects to extend its system in the near future, and to erect some table lines.

CONSTRCTION.

BEAUFORT, S. C.—The Peoples Telephone Co. have commenced the extension of their system to Yemassee. They expect to complete the work by January 1st, after which they contemplate further extensions.

BONESTEEL, S. D.—A telephone line is to be extended from St. Elmo to Herrick and also to Burke and Gregory.

RAMSEY, S. D.—A telephone line is being extended from Ramsey to Clarno.

SALEM, S. D.—The Salem Telephone Co. will begin the construction of rural lines at once.

LOCKHART, TEX.—The Smithville Telephone Co. is making extensions to its local system.

ORWELL, VT.—The Co-operative Telephone Company will extend its lines to Shoreham and later connect with the Peoples lines at Brandon.

WHITE RIVER, VT.—The Peoples Telephone Co., it is reported, are making extensive improvements.

SISTERSVILLE, W. VA.—The West Virginia Telephone Co. will construct new circuits to connect this town to Parkersburg and will erect a cable over the Ohio river at Matamoras.

A TELEPHONE AIDS AT A WRECK.

PRACTICAL illustration of the sometimes urgent need for telephone facilities was recently given in Columbus, Ind. A train wreck occurred on the Pennsylvania lines one afternoon. It happened that at the moment the disaster occurred an interurban car on the lines of the Indianapolis, Columbus and Southern Traction Company, which parallels the railroad at that point, was passing.

The traction conductor asked the motorman to put on all power and, hurrying to the nearest telephone box, he notified Joseph I. and William G. Irwin, of this city, owners of the Indianapolis, Columbus and Southern Traction Company, who immediately summoned all the physicians in town and sent a special car at top speed to the scene of the collision with Drs. B. Fitzpatrick, G. T. McCoy, W. H. Butler, D. J. Marshall and E. U. Wood. Shortly after their arrival the remainder of the physicians of the city were on the scene, having gone out in a second special car within a few minutes after the first one left.

A REMARKABLE MACHINE?

THE following news item taken from a Southern newspaper may prove of interest to some of our readers, as illustrating a new field for the usages of storage batteries and charging: "The local exchange of the East Tennessee Telephone Company has recently installed an expensive new apparatus which will improve the service, and enable the exchange to extend its business. The machinery consists of a new Holtzer-Cabot charging machine of two and one-half horse-power of 160 amperes, and new storage batteries, and by it an operator at the exchange can tell within a few yards of where a wire difficulty lies."

THE AMERICAN TELEPHONE JOURNAL

A Talk on the Representative Telephone Paper

All agree that Manufacturers must advertise their product. The question is, How?

Experience says: Select the Right Medium; then stick to it persistently.

We offer the following letter as a proof that this paper is the right medium:

"I think more of your Journal than of any other telephone paper published. Each week it contains practical and invaluable information."

FRED PETERSON, Mgr.,
Clarion & N. W. Telephone Co.,
Vernon Farmers' Telephone Co.,
Clarion, Iowa.

The Right Medium is the Representative Paper in its field. THE AMERICAN TELEPHONE JOURNAL has received a thousand and a half voluntary letters of praise from subscribers and advertisers. Surely this marks it the Representative Telephone Paper.

PAUL LATZKE, President WILLIAM H. McDONOUGH, Editor

Vol. 10 NEW YORK—DECEMBER 24, 1904—CHICAGO Number 26

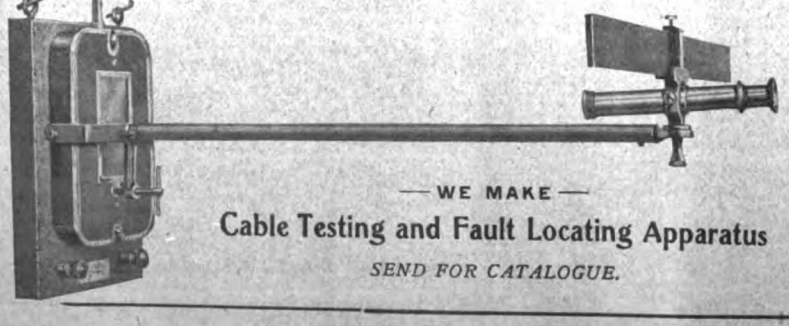
ELECTRICAL MEASURING INSTRUMENTS

D'ARSONVAL GALVANOMETER TYPE P.



Stimulated by the large demand for a good Galvanometer at a reasonable price, we have gotten out this instrument. It is well made, of finished workmanship, pleasing appearance and excellent working qualities. Its low price is due to good design, careful manufacture and production in quantity, and in no detail to poor material or slighted workmanship. It has the following desirable features: Simplicity of construction, attractive appearance, the moving system always entirely visible, a proportional scale, a damped system and quick working, strong suspensions that allow no zero shift, ample coil clearance and a sensibility that is ample for all ordinary electrical measurements and many precision measurements.

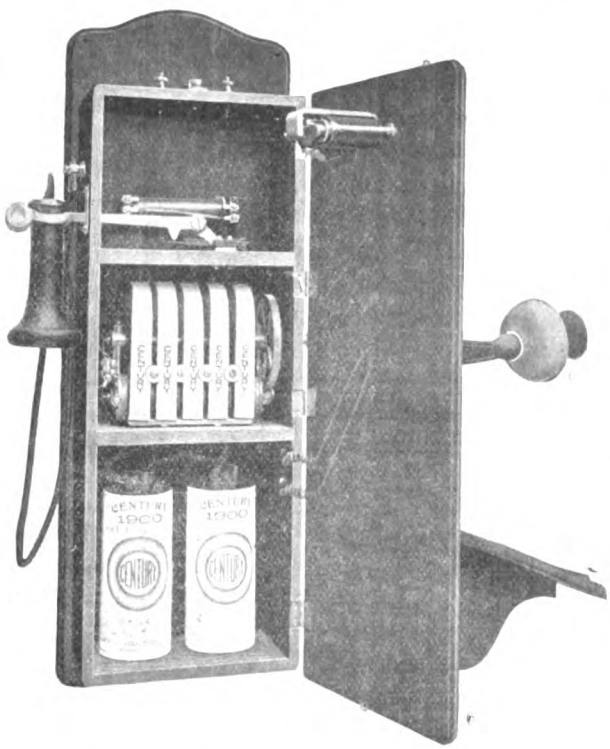
CENTURY
100% GOOD

Century Magneto Telephones



are all equipped with the most reliable and efficient transmitter yet devised. This transmitter is provided with **electrodes of pure platinum** metal; making it entirely free from "frying" and "sizzling" sounds, packing and all other transmitter troubles.

Century Telephones will talk better over longer lines than any other telephone made.

We will send you a transmitter to use on your switchboard on 60 days trial, charges prepaid, to give you an opportunity of testing same.

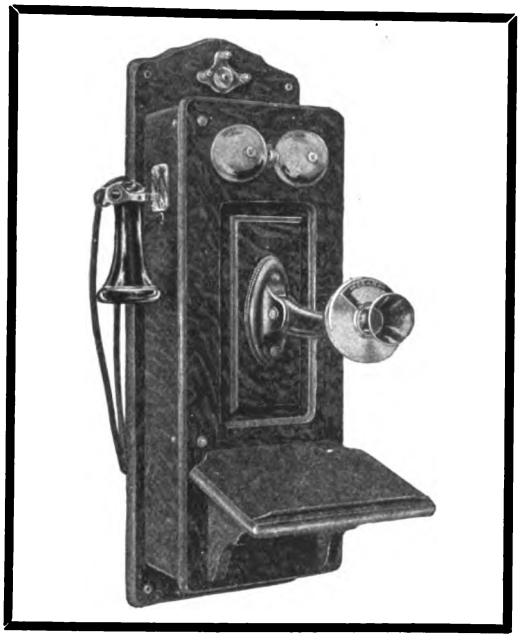
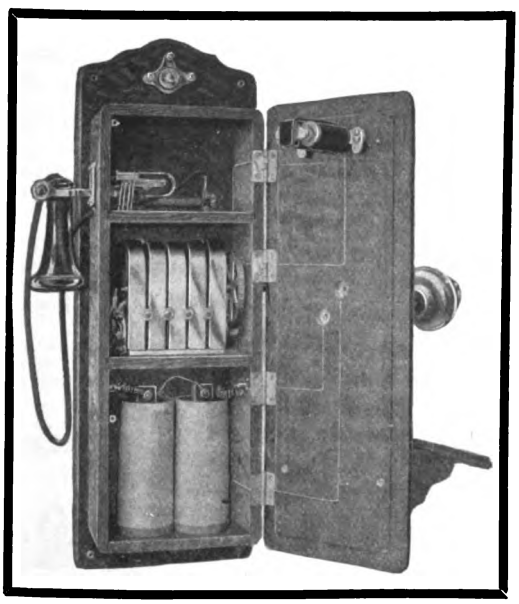
DEAN

TELEPHONE APPARATUS





SOME of the reasons why Dean Telephones are enthusiastically adopted after a thorough trial. Each telephone has:

¶ A hook switch with a removable lever which is normally *securely* locked in place by a spring catch. When removed, prevents breakage in handling and shipping.

¶ A transmitter arm which can be removed without disturbing the transmitter wiring.

¶ A very sensitive ringer, made so by the new Dean construction which absolutely prevents sticking.

¶ A powerful generator which has stood the test of time.

¶ A self-contained arrester with lock-nut line binding posts. An effective device.

¶ A tapper guard for protecting the ringer from injury.

¶ Four hinges with soldered connection spiral springs to carry wiring to the cabinet lid—does away with loose cords.

¶ Two locks which will not fall out when the cabinet lid is open.

¶ Mounting holes in corners of backboard metal bushed so as to prevent splitting or marring of woodwork.

¶ Circuit wiring run in grooves in woodwork which are afterwards filled with hot beeswax to prevent entrance of moisture—gives permanent and lasting results.

¶ All exposed metal parts entirely insulated from circuit, preventing disagreeable or dangerous shocks.

¶ And last but not least—A talking circuit consisting of the new Dean transmitter, receiver and induction coil, which will talk perfectly through the longest lines.

These telephones can be finished in quartered oak or walnut woodwork

---

We also make telephones for other classes of service. Let us tell you about them in our little Booklet No. 2, which will be mailed upon request

TELEPHONE EXCHANGE ENGINEERING.

ARTICLE XXI.—CONDENSERS (CONTINUED).

BY RAY H. MANSON, ALBION D. T. LIBBY AND CHARLES A. SIMPSON.

EACH manufacturer has a certain schedule of tests to which the completed condensers are subjected. These tests can be divided into four classes: *First,* a direct current flash test for crosses between the terminals and between the terminals and case. *Second,* an alternating current test for strength of insulation. *Third,* a test for electrical capacity. *Fourth,* an insulation resistance test. It is best to make the tests in the order named, as heavy currents may damage the capacity and insulation.

1. *Direct Current Test-Flashing:* The apparatus and circuits necessary for this test are simple. Direct current is passed through a bank of lamps, as shown in Fig. 90, so that a short circuit of the terminals will not do damage. The application of the direct current circuit terminals to the condenser terminals will indicate a cross between the condenser plates by the illumination of the lamps, while the same test applied to the metal case and each terminal in succession will show which of the plates is grounded on the case. The most common cause arises when one of the tin foil plates comes into metallic contact with the other plate. This might be due to a mechanical shock or metal particle, and can, in some cases, be removed by mechanically jarring the condenser. A more permanent cure can be secured by resorting to a flash test, which is accomplished by applying the handles, shown in Fig. 90, to the condenser terminals. The short circuit within the condenser will then become heated, as considerable current will flow, and the foil around the point will be burned away. Thus with no appreciable damage to the condenser the trouble is permanently cleared.

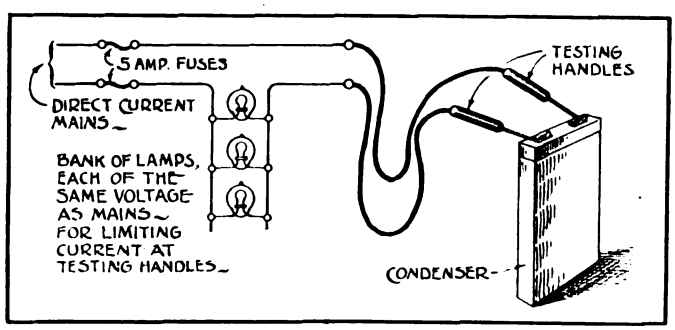

Fig. 90. Direct Current Condenser Test-Flashing.

When a short circuited condenser is attached to a direct current circuit, a flash will appear, and if the short circuit is cleared there will be no flash upon attaching the condenser the second time. Thus it is not necessary to have a bank of lamps in the test circuit to know by their lighting whether the condenser is short circuited or cleared. However, when the lamps are not used the direct current circuit should be protected by 5-ampere fuses. The flash test is a convenient way for the telephone company's repair man to clear condenser troubles, and is practically the only way to redeem broken down condensers.

2. *Alternating Current Test:* This test is similar to that just described, but an alternating current of about 60 cycles and from 220 to 400 volts pressure is substituted for the direct current source. This pressure is applied to the condenser terminals for about a minute, and if there are any weak places in the insulation which are liable to give trouble when the condenser is in commercial use, it will show by breaking down the insulation (dielectric material) and crossing the plates

Alternating current is not so easily handled in testing as the direct current, due to the fact that it will "flow" regardless of the condition of the insulation of the condenser plates from each other. If the condenser breaks down, and a low resistance cross results, the test lamps will light to their full brilliancy. These lamps should be of the same voltage as the alternating current circuit, so that they will not burn out if the condenser breaks down. The formula for condenser reaction given in a previous chapter (A. T. J., Vol. 10, page 163) shows an apparent resistance of 1,327 ohms for a two microfarad condenser, when subjected to a 60 cycle alternating current flow. With a 220 volt, alternating current testing circuit, less than 0.15 of an ampere will flow through the condenser, which is not sufficient to light the test lamps. In case of a breakdown this resistance is reduced to zero and the 220 volt lamps light to full brilliancy.

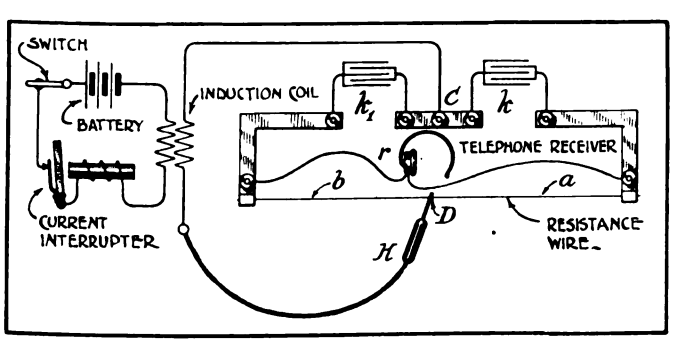

Fig. 91. Slide Wire Bridge Method of Measuring Capacity of Condensers.

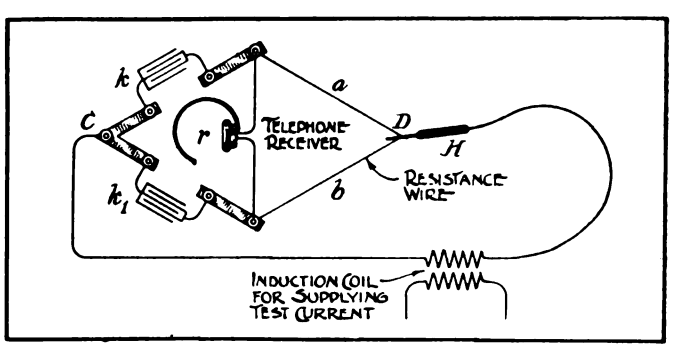

Fig. 92. Wheatstone's Bridge Illustrating the Principle of a Slide Wire Bridge.

3. *Capacity Tests:* The capacity of a condenser can be tested in many ways, but the most convenient commercial method is by the use of the simple *slide wire bridge.* The wiring of this test circuit is shown in Fig. 91, while a simplified diagram of the

Digitized by Google

same circuit is given in Fig. 92. The latter will be recognized as the familiar Wheatstone bridge circuit. It has been previously shown that different capacities have different apparent resistances to an alternating current of constant frequency, the larger capacity acting as a smaller resistance. Now, if an alternating current is applied to the points C and D of the bridge, it will be possible to adjust the resistances in the arms of a and b so as to produce a "balance" and prevent any current from flowing through the telephone receiver r.

Then $a : b = k : k_1$.

With a equal to b or the handle H in contact with the middle of the slide wire, the unknown condenser will have the same capacity as that of the standard. With the unknown condenser

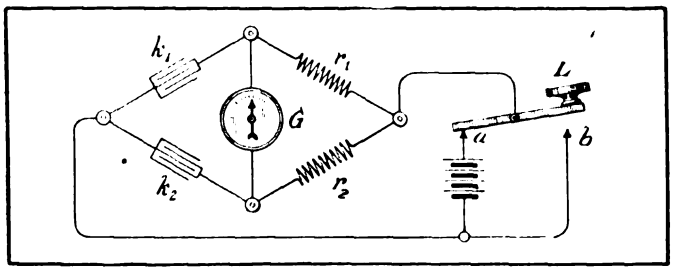

Fig. 93. Wheatstone's Bridge Method of Measuring Capacity of Condensers.

of higher or lower capacity it will be necessary to go to the right or left of this central mark to obtain a balance. In practice it is usually convenient to calibrate the slide wire so that it will read directly in microfarads. The best results are obtained when the standard condenser is taken with a capacity same as those under test should be. In the factory test for capacity, all condensers measuring below the standard are rejected, while those within an allowable percentage above are passed. It is customary to place a plus (+) sign after the capacity figure when marking condensers which have a capacity slightly greater than the standard.

Wheatstone Bridge Method: Fig. 93 shows the Wheatstone bridge method of measuring the capacity of condensers. The condensers k_1 and k_2 are connected in the two arms of a standard type Wheatstone bridge, and the resistances r_1 and r_2 adjusted so that there is no deflection of the galvanometer needle on the charge or discharge. The condensers are charged when the key L is thrown into contact with a and discharged when in contact with b. The bridge is balanced when $k_1 : k_2 = r_2 : r_1$,

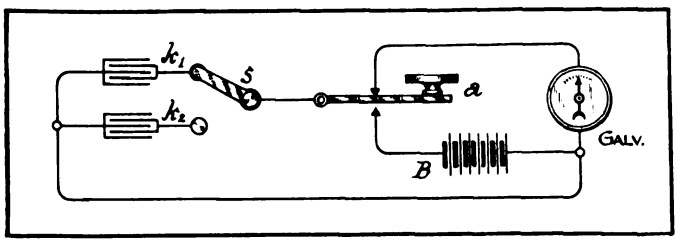

Fig. 94. Galvanometer Method of Measuring Capacity of Condensers.

the *larger* capacity acting as the smaller resistance.

For example, k_1 is a standard 2 M. F. condenser, and it takes resistances $r_1 = 400$ ohms and $r_2 = 300$ ohms to cause a balance.

The unknown capacity $k_2 = \frac{k_1 r_2}{r_1} = \frac{2 \times 300}{400} = 1\frac{1}{2}$ M. F.

Galvanometer Method: Another method of testing the capacity of condensers is by means of a ballistic galvanometer or other measuring instrument having the same properties. A ballistic galvanometer is an instrument designed to measure the strength of electric currents, which last only a short time, by the throw of a pointer or needle which takes a relatively long time to swing. In other words, the moving parts of the instrument are made heavy and are thus slow to move, but are free from any "damping" action so as to get the full effect of the electrical impulse.

The ballistic galvanometer test requires the comparison of two readings obtained by first charging a condenser of known capacity k_1, by a constant pressure, direct current, producing a deflection d_1, and then repeating the operation on the condenser of unknown capacity k_2, giving a deflection of d_2. The unknown capacity is then: $k_2 = k_1 \frac{d_2}{d_1}$.

The connections for this test are shown in Fig. 94. The switch s allows either the standard or unknown condenser to be connected. Pressing key a closes contact with one pole of the battery B, which is preferably of about 150 volts pressure, while releasing the same key allows the discharge from one or the other of the condensers, according to the position of the switch s, to pass through the galvanometer and give a swing to the needle which can be easily read.

For example, suppose that the full swing of the needle for the standard condenser of 2 M. F. capacity was 104 divisions and that of another condenser only 78 divisions. The unknown capacity is given by the above formula:

$$k_2 = k_1 \frac{d_2}{d_1} = 2 \frac{78}{104} = 1\frac{1}{2} \text{ M. F.}$$

If the standard condenser is of the adjustable type, it would be found expedient to adjust its capacity so that the two galvanometer readings are the same; when the unknown capacity will be equal to the amount of the standard capacity then in the circuit. In other words the nearer the ratio $\frac{d_2}{d_1}$ is to unity the greater the accuracy of results.

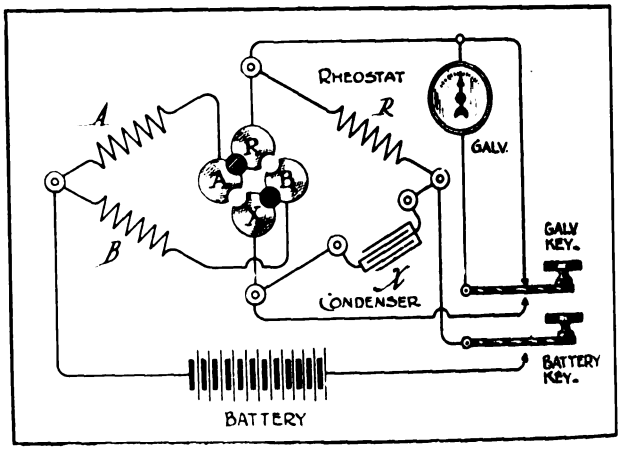

Fig. 95. Wheatstone's Bridge Method of Measuring Insulation Resistance of Condensers.

3. *Insulation Resistance:* The insulation of one plate of a condenser from the other is never perfect, and thereby allows current to leak through the insulating medium. On account of the high resistance of this insulating medium, its value is expressed in megohms; a megohm being a convenient term for a million ohms. Commercial telephone condensers are made with insulation resistances of from ½ to 50 megohms, according to the use to which the condenser is to be put and the space allotted to it.

One type of 2 M. F. condenser used in a common battery telephone is made with a low insulation resistance of about 3½ megohms. As this condenser is normally in the line circuit when the telephone is not in use it is leaking central battery current on an average of 23½ hours per day, one-half hour being allowed for conversations. This waste of current is negligible, even in a 10,000 line exchange (10,000 bridged condensers), as the insulation resistance of one condenser is 3,500,000 ohms or a total of 350 ohms for the entire exchange cited.

Insulation resistance can be measured by means of the Wheatstone bridge, voltmeter or galvanometer.

Voltmeter Method: A high resistance voltmeter is often used for measuring the insulation resistance of condensers.

Wheatstone Bridge Method: Up to 10 megohms the insulation resistance of a condenser can be measured on a standard

Digitized by Google

Wheatstone bridge. In testing such high resistance, however, it is necessary to provide a battery or direct current source of at least 100 volts. The bridge is then operated as in measuring ordinary resistances. The ratio of the bridge arms *A* and *B*, Fig. 95, should be taken as 1 to 1,000.

For example, a condenser under test requires 3,500 ohms in the rheostat of the bridge in order to cause the balance, the arms *A* and *B* being respectively 1,000 and 1.

Then $X = R\frac{A}{B} = 3{,}500\frac{1{,}000}{1} = 3{,}500{,}000$ ohms or 3.5 megohms. While small portable testing sets are designed for these high readings, there are discrepancies and difficulties entering into their practical use, especially where many condensers are to be measured. For these and other reasons, chiefly the low range (less than 10 megohms), this type of instrument is not used in commercial condenser testing.

REPORT OF THE INTERSTATE CONVENTION

By Special Representative.

THE fourth annual convention of the Interstate Telephone Association began its opening session in the banquet hall of the Auditorium Hotel, in Chicago, Tuesday afternoon, December 13. President Henry A. Barnhart, of Rochester, Indiana, was in the chair. E. M. Coleman, of Louisville, Kentucky, served as secretary.

As soon as the convention had been called to order, at the suggestion of the secretary, a credential committee of three was appointed to assist the secretary in limiting the attendance to properly accredited representatives or members. W. Mathews, of Kentucky, F. C. Holdoegel, of Iowa, and Mr. Flee, of Ohio, were appointed to this committee.

Mr. Holdoegel quoted the resolution passed by the last convention recommending that at future meetings no one be admitted at any session without proper credentials, and moved that the word executive be inserted before the word sessions. The motion was carried.

These preliminaries having been disposed of President Barnhart read his annual address, and was followed by Secretary Coleman, who read the annual report. After the reports were read the president appointed Mr. Gibbons, of Missouri, doorkeeper during the sessions of the convention, and then George N. Bandy, of Iowa, was called upon for the report of the committee appointed to investigate the attitude of express companies toward Independent telephones. Mr. Bandy said that as express companies had generally changed the methods complained of he had thought it unnecessary to make a detailed report.

The question of consolidation with the National Association was called up, and the minutes were read of a joint conference between the officers of the two associations held at the Auditorium November 18, 1904. These minutes included written statements by the president of the Interstate and the president of the National Association in regard to the meeting, and to their attitude toward the consolidation movement. It appeared that the conferees were all heartily in favor of the plan, but the committee representing the Interstate Association had no power to act. A resolution was therefore adopted pledging the members to secrecy in regard to the movement until after the annual convention of the Interstate Association, when a committee would be appointed with power to act to meet a similar committee from the National Association.

After accepting an invitation to visit the plant of the American Steel and Wire Company, at Waukegan, Thursday afternoon, the association went into executive session to consider the matter of uniting with the National Association.

Wednesday's Session.

THE association held an interesting session Wednesday afternoon for the consideration of papers on various subjects important to Independent telephony. One of the most important of these had to be omitted because of the illness of O. M. Bake, vice-president of the Miami National Bank, at Hamilton, O. Mr. Bake had been assigned the subject, "Why Independent Telephone Securities Do Not Command the Market Price They Deserve According to Their Earning Capacity."

Theo. Thorward, president of the Indiana Independent Telephone Association of South Bend, Ind., read a paper on the subject, "What the Independent Telephone Companies Owe the Public; What the Public Owes the Independent Telephone Companies."

In the discussion of the paper which followed, the question was raised as to the attitude of the Illinois Telephone Company in Chicago toward the Independent companies who are trying to get into the Chicago field. Mr. A. B. Conklin, of the Interstate Independent Telephone and Telegraph Company, was asked to reply, as his field of operations immediately adjoins the Chicago territory. Mr. Conklin replied that his company had not been turned down by the Illinois company, and yet they were feeling somewhat discouraged in the matter. They had made application for connection with the Illinois companies' lines, and had even offered to put in the connecting line at their own expense, but had not yet received the desired permit, action having been postponed from time to time. Mr. Conklin stated that the matter was of considerable importance to Chicago people, as the Interstate company could now give them access to seventy-five thousand telephones over first-class lines.

An interesting discussion was precipitated by the announcement that Mr. Richmond, an Independent telephone operator from Southern Wisconsin, was present in search of light. He was considering an attractive proposition from the Bell people, who desired him to connect with their toll system

Mr. E. D. Graham, of the Mexico Telephone Company, Mexico, Missouri, read a short paper on the subject, "Manufacturers' Duties and Their Dues." Mr. Graham's conclusions were that it is the efficiency of the service that counts, and that this efficiency cannot be attained without good construction and good apparatus. It is the duty of Independents to uphold the hands of the people who make good apparatus, and to encourage Independent manufacturers as far as possible. The duty of the manufacturer is to protect the people to whom they sell apparatus and to give them the best equipment that can be made, rather than to find a market for their goods by organizing competing companies.

On motion of A. C. Barber, the chairman was instructed to appoint a committee of three to wait upon the Illinois Telephone Company and ascertain its intentions in regard to connecting with the Independent lines. The chairman appointed Mr. Barber, Mr. Veneer, of Kankakee, and Mr. Thorward, of South Bend.

Mr. John E. Jones, of Jonesboro, Arkansas, appeared as a substitute for Mr. J. H. James, president of the Minnesota Independent Telephone Association. His subject was "Uniformity of Equipment and Standardization of Apparatus the Imperative Demand in the Operating Field."

Thursday's Session.

THE association in executive session had voted to consilidate with the National Independent Telephone Association according to plans to be formulated by a joint committee of five from each organization. The session of Thursday, therefore, was the final meeting of the Interstate Independent Telephone Association.

Digitized by Google

After the convention had been called to order the president appointed the following nominating committee to select officers for the ensuing year: Messrs. Lichty, of Iowa; Graham, of Missouri; Hull, of Illinois; Mathews, of Kentucky; Harper, of Wisconsin; Fee, of Ohio, and Reeves, of Indiana.

A short discussion of the subject which had been assigned to O. M. Bake, of Hamilton, O., "Why Independent Securities Do Not Command the Market Price They Deserve According to Their Earning Power"; then followed, the concensus of opinion, ascribing the reason to the practice which obtains among brokers of calling in Bell men to determine the value of these securities.

H. C. Barber, of Ottawa, Ill., chairman of the committee appointed to confer with President Wheeler, of the Illinois Telephone Company, of Chicago, and ascertain the intentions of his company toward the Independent lines, reported. Mr. Barber said that the committee had had a pleasant conference with Mr. Wheeler, who had informed them that his company stood ready to connect with any Independent company at the city limits whenever he could be assured by responsible parties that such Independent company possessed standard construction and equipment.

As Mr. Conklin, of the Interstate Independent Telephone and Telegraph Company, had explained Wednesday the repeated attempts his company had made to connect with the Chicago concern, the question arose what would be considered "standard." Mr. Barber stated that from the remarks of President Wheeler he thought that any first-class construction and equipment would be acceptable. There being no better constructed system in America than that built by the Interstate Company, now seeking entrance into Chicago, a motion was made and carried that the committee, with Mr. Conklin added, be further instructed to go to President Wheeler and present to him in a proper manner the facts concerning the Interstate lines and ask for a connection as soon as possible, according to his promise.

Of the four papers announced on the programme only one was read. Senator Rome C. Stephenson, of Rochester, Ind., presented a carefully prepared paper on the subject, "How to Avoid Personal Injury and Responsibility in Telephone Construction Work and Maintenance."

Mr. Stephenson stated that it would be impossible to lay down any rules that would avoid all responsibility, but certain safeguards could be adopted whereby the loss could be reduced to a minimum. He cited the importance of using material not defective, notably cross arms which are free from all knots and decay. The courts hold the company liable in cases of accident from defective material known to the company and not known to the workman. A corporation is not bound to use the best material and appliances that can be obtained, but is required to use all reasonable care and to purchase material and appliances that are reasonably safe. If it does not, it will be held responsible for all injuries received on account of that neglect. Therefore it is important that all material should be carefully inspected by a competent and reliable inspector before being used.

Especial care should be taken to keep telephone wires away from electric lines carrying a heavy current. If necessary to cross such lines, a space of at least four feet should be left between them to allow for sagging, and a guard wire should be placed below if possible.

Courts have decided that electric lights and trolley lines should be constructed so as not to interefere with telephone lines. When a telephone company uses the ground for the return circuit, and an electric railway operates also with a single-wire system, using the ground for the returning current, but in such a way that abnormal electric conditions result, the courts have held that the railroad company is liable to the telephone company for damages ensuing.

It is often unavoidable to place telephone wires near electric lines, in which event there should be regular and systematic inspection at the danger points. Dead wires should be removed or fastened up out of reach in case they should ever become alive. Only by exceptional vigilance can a telephone system be constructed so as to reduce the danger of accident to the minimum point.

Messrs. Stanton, Young, Thompson and Johnson participated in the discussion which followed. The principal points emphasized were the necessity of employing competent men and the advantage of carrying an ample indemnifying insurance.

L. L. C. Brooks, of St. Paul, chairman of the committee appointed to confer with the United States Postoffice Department concerning the order issued by Postmaster Payne to the effect that only Bell telephones should be used in postoffices, could not be present. His report was read by the secretary. It developed from the reading that the committee had done an immense amount of work and had accomplished a great deal of good, principally in calling general attention to the excellence and growth and importance of the Independent telephone systems. They had ascertained that Postmaster-General Payne had been an officer and stockholder in a Bell company. He acknowledged that such instructions had been sent out and that but one telephone system would be used by the department, and that one having connections with Washington. Such a storm of protest went up from all over the country that the department had to materially change its views. As a result, the orders are no longer carried into effect, and the department head stated that hereafter each case would be decided on its merits. The committee attacked the department in its most vulnerable point, namely, in the appropriation bill. A clause was added to the bill which passed the House to the effect that no part of the appropriation be expended in any office where the postmaster is required to use no telephone except the Bell. This clause was stricken out in the Senate, as the bill finally passed contains no reference to the matter.

The report of the treasurer, A. B. Conklin, was read. It showed an empty treasury, except as to the money received from new members during the convention. As there were a number of claims unpaid Mr. Barber, of Ottawa, Ill., was appointed chairman of a committee to audit the bills and raise sufficient money among the members to take care of all just claims.

On motion of Mr. Thompson a vote of thanks was extended to the retiring officers of the association.

The appointment of a committee of two from each State was authorized to gather information as to the condition of Independent toll lines, and forward this to the committee, who is to wait upon the Illinois Telephone Company. The committee is to report not later than January 15, 1905. The names of the committee will be announced to the secretary later.

A STUDY IN TRAFFIC.

By the Traffic Manager.

THE figures which have preceded have illustrated loads which may be expected in a large city, a medium-sized one and in manufacturing and rural communities of small size. It remains to consider the proper load line of a village; for, while the subscribers in centers of this description do not form a large proportion of the total telephonic clientele of the country, the number of small exchanges of under 500 subscribers is numerically very large, and consequently of corresponding importance.

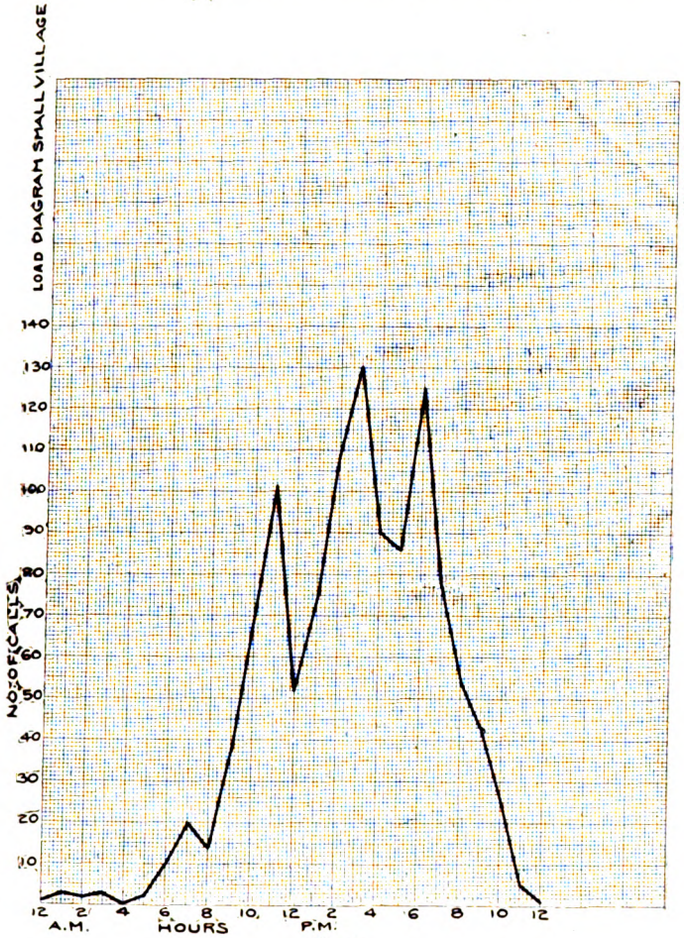

Fig. 7.

Fig. 7 is a load line from a village of about 2,000 inhabitants, served with a non-multiple switchboard of three positions, containing about 200 lines. The diagram presents a striking contrast to those which are obtained from larger centers. The first noteworthy feature is the decided peak occurring at 7 A. M., and then succeeding this is another peak at 11 A. M. The reduction in the rate of traffic which inevitably occurs during the middle of the day is here noticeable as taking place at exactly 12 o'clock, and is relatively greater in proportion to the total load line than is found in larger places. In the afternoon there are two peaks, one at three o'clock and one at six. But little study is necessary to convince the reader that an inspection of the load line of a telephone exchange reflects with the utmost fidelity the daily habits and customs of the town from which it is taken. It is exceedingly instructive to transform the total load lines obtained from telephone exchanges in such a manner as to show the number of messages per line instead of the gross load in calls.

In figure 8 this transformation has been performed for tne load diagram previously shown in Fig. 3. As this is simply a transformation of co-ordinates, the shapes of the diagrams giving the total load of messages per line are similar. But the diagrams showing the messages per line is particularly instructive, as indicating the rate at which telephonic business is received. An inspection of Fig. 3 indicates a great difference in the total loads between the lines of the outlying offices and those of the main exchange. In Fig. 8, however, this difference is markedly reduced, thus showing that, while the gross loads of the main office and its companions may differ very widely, the messages per line in all districts closely approach each other.

Fig. 9 shows a similar transformation made for the load lines of Fig. 4; and in this case the difference in the relative co-ordinates is still less marked, showing that in the medium-sized city the call rate in the office district and in the outskirts is nearly the same.

A knowledge of the unit loads to which the various parts of the telephone plant may be properly subjected is of the greatest value to the general manager, as showing whether all parts of the exchange are working at the proper rate or not; and it is vital to the engineer to enable him to design adequate equipment to fit new conditions. Traffic record forms the only basis from which accurate statistics of this description can be obtained.

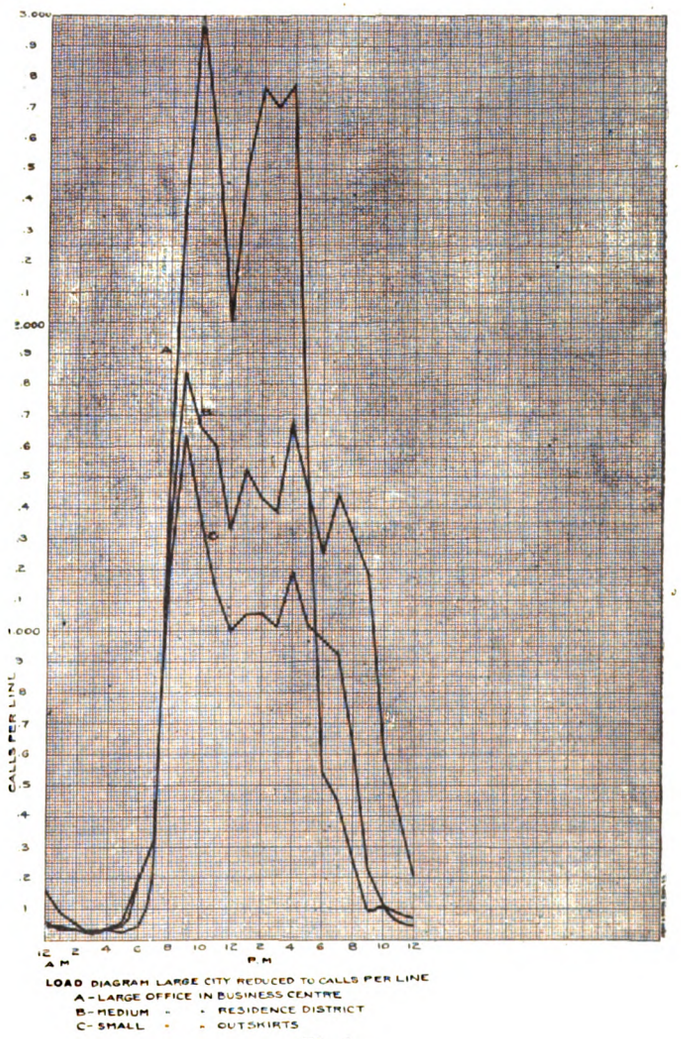

Fig. 8.

one of its most useful purposes is that of supplying information to be used in this manner.

Fig. 10 is a diagram giving information relative to the loads which operators are able to carry. In this diagram the lower scale represents upon a percentage basis the total number of returns which have been employed in constructing the curves. The left-hand scale represents the number of calls per day. In the top of the chart four curves will be found. The first pair (Nos. 1 and 2) refer to the total number of calls which operators handle

Digitized by Google

per day. No. 1 relates to the operators under flat-rate service, and No. 2 those working upon measured service positions. The other pair refer to the number of calls in the busy hour, No. 3 dealing with flat-rate positions, and No. 4 those containing measured service lines. This chart is based upon returns from exchanges in large cities, and the method of using it can best be explained by example. For instance: Select, say, 1,700 upon the right-hand scale, follow horizontal towards the left until curve No. 1 is intersected, and thence a vertical line to the bottom of the sheet, finding 55 per cent. The interpretation of this result is that 45

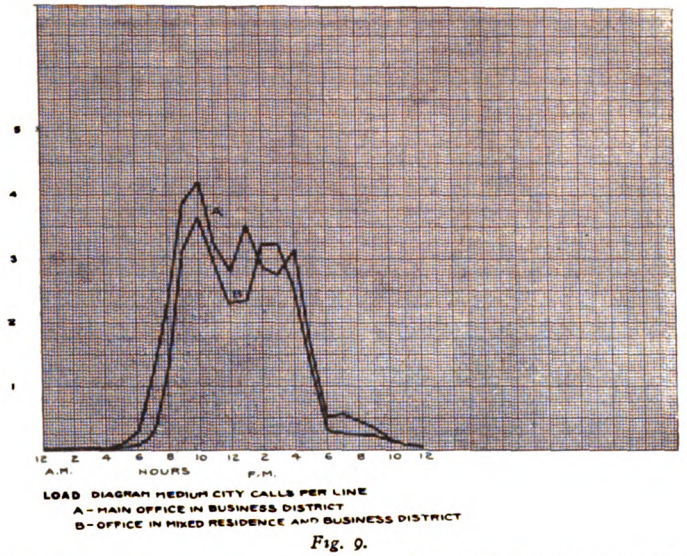

Fig. 9.

per cent. of the operators under consideration handle 1,700 or less calls per day, while 55 per cent. handle 1,700 or more calls per day. Again select, say, 2,100 upon the right-hand scale, follow a vertical to the same curve, then a horizontal to the bottom of the sheet and 9 per cent. is found; which means that 9 per cent. of the operators from which the returns have been secured handle 2,100 calls or more per day, and 91 per cent. 2,100 calls or less.

Curve No. 2 is drawn to the same scale, and from it statistics may in a similar fashion be obtained relating to work upon measured service positions. The curves 3 and 4 are read in the same manner, giving information as to the loads in the busy hour.

Curve 5 is plotted to show the ratio between the work done by operators upon measured service positions and those upon flat rates.

For this curve the same bottom scale is used as applies to the preceding ones, while the ratio scale is to be found upon the left-hand side of the sheet. For example, take 90 per cent. upon the bottom scale and follow a vertical to curve 5, thence a horizontal to the left-hand side; 54 per cent. is obtained, this means

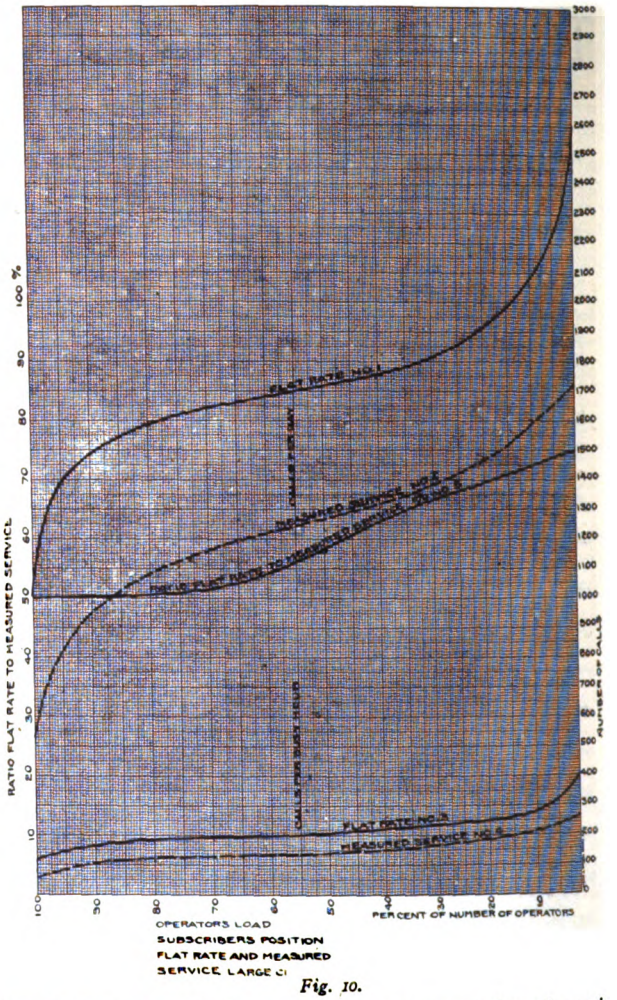

Fig. 10.

that 60 per cent. of the operators upon measured service work handle 54 per cent. or more of the calls done by flat-rate operators, and that 40 per cent. handle 54 per cent. or less.

Subsequent loads of operators working in smaller cities, and those which may be used with trunk work will be discussed.

EDITOR'S NOTE:—This article is the third in the series dealing with traffic conditions.

FIGHT AGAINST BELL IN MISSOURI.

RESOLUTIONS adopted by the Retail Grocers, Butchers and Bakers' Association and by the Retail Druggists' Association, of St. Joseph, Mo., pledge the members of those bodies to cause the removal of the instruments of the Missouri & Kansas Telephone Company from their places of business if the annual rental of the telephones is increased to $60 January 1, as has been announced by the Bell Company.

The grocers and butchers adopted a resolution, declaring that they would refuse to pay the increased rental. The druggists then met and adopted a similar resolution. A representative of the Grocers and Butchers' Association addressed the druggists, urging them to co-operate in the effort to prevent the increase in the cost of Bell telephones.

"We pledged ourselves to discontinue the use of Bell telephones after January 1, unless the price remains where it is now," said President G. W. Akers, of the Retail Grocers and Butchers' Association.

"We are paying $50 per year for the Bell telephone now. Some time ago, representatives of the Missouri & Kansas Company called upon the merchants of St. Joseph and told them that the service was to be improved by the installation of metallic circuits. Many merchants were persuaded to allow the change. Those who refused to yield were told that metallic circuits would be put in whether they liked it or not and the price would be $60 per year, an advance of ten dollars. We cannot afford to pay that price when the Citizens' cost but $40 per year."

Contained in the Missouri & Kansas Telephone Company's contract for this year is the following extraordinary provision, which seeks to permit the company to readjust its rates in the event the city, county, or State attempts to make any change in the corporation's rate of taxation:

"If the city, county, or State in which the subscriber's telephone is to be located, shall require payment of any license, privilege or occupation taxes, fees, rentals, or similar charges by the company on account of its business or property, other than that mentioned in the city ordinances accepted in writing by the company, then there shall be added to the rate herein and paid to the company in the same manner as such rate, such proportionate part of the total amount for each year of such taxes, fees, rentals and charges as the number of telephones in use in the city, county or State bears to the total annual amount of such taxes, fees, rentals and charges."

QUERIES

Questions on any subject relating to telephony will be answered on this page.

LONG-DISTANCE LEADS.—(475.)

We are contemplating changing the lead of a long distance line carrying a number of circuits. We can save a long distance by crossing the bed of a creek, which is frequently quite dry. What bracing do you advocate?
G. L.

A method frequently used in building power and telephone circuits where there is an extra amount of stability required is to use two poles and place the cross arms as shown in Fig. 475. Such

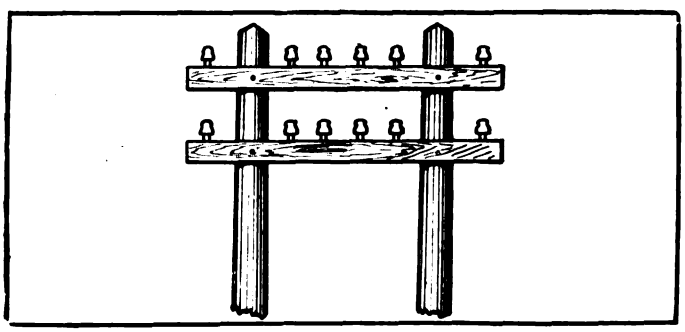

Fig. 475.

a scheme should meet your requirements and, if properly braced, will be as nearly permanent as it is possible to make a line. This is commonly called an H fixture.

LOCATING OPENS.—(476.)

What is the best method of locating an open wire on a copper metallic circuit?
T. R. S.

It is very difficult to locate accurately the position of a break in a conductor. If the line is highly insulated and the break is free from all grounds, it is possible to obtain the approximate location by measuring the capacity of the line, provided the capacity per unit of length is known. Thus, for example, in an underground cable, the position of the ruptured end of the conductor may be ascertained by measuring the capacity of a neighboring conductor, and then the capacity of the ruptured one up to the break. It is often desirable to make a measurement from each end, in order to locate the break more accurately. If the broken wire is grounded at the ruptured end, any one of the various loop tests may be used for the purpose of locating the break. Finally, if the wire is partially grounded at the break, the problem becomes a very difficult one, and usually impossible of solution.

COMMON BATTERY SYSTEMS.—(477.)

What is the voltage of common battery systems? Can ordinary magneto apparatus be converted to work on a common battery system, and what additional apparatus is needed?
G. N. J.

Common battery systems are operated with different voltages. The Bell companies use 24 v. for local work, but sometimes resort to 48 v. for long-distance operation. This additional voltage is used, however, to operate the signals. Some of the Independent manufacturers use 48 v. for general operations, others 30 v., and some 24 v. It is impracticable to attempt to reconvert magneto instruments to operate on common battery systems for several reasons. In the first place, the primary circuit of the induction coil has too low a resistance and the transmitter has a similar trouble. Then the secondary circuit of the coil has too high a resistance for good operation; again, the circuits would have to be entirely rearranged and a condenser added. In fact, the only part of the instrument that remains the same is the ringer. When a change is made from magneto to common battery a condenser is cut in series with the bell circuit of the magneto instrument to prevent it shunting the line and causing the line signal to operate. This is only a temporary arrangement to allow the use of the old magneto instrument till it can be changed for a common battery one.

TRUNK TROUBLE.—(478.)

We have the following trouble on a long trunk line: When *A* calls *B* the circuit seems O.K.; but if *B* calls *A*, quite frequently it is impossible to carry on a conversation, and the line is very noisy; that is, it hums badly at night. What is the trouble?
A. B. C.

From your description the trouble might possibly be in the trunk calling cord of the exchange at *B*. There may be a loose connection somewhere in the cord circuit which goes open at times. This would account for the noise on the line and also for the difficulty in carrying on a conversation. Look over the cord carefully and test it for a cut out, also see that the plug is not worn too much or is dirty. Examine all the connections to the keys, and if you employ a repeating coil, go over this very carefully. An open circuit, such as you seem to have, sometimes occurs at the ringing key, and thus the trouble when *B* calls *A* can be accounted for.

OHM-METER CIRCUIT.—(479.)

Enclosed find an ohm-meter circuit for general testing. Please inform if combinations are correct for satisfactory results. If not, please correct.
J. W. N.

In reply to your query respecting ohm-meter circuits, we found it very difficult to trace the connections shown upon your drawing; therefore, in order to answer your query, we herewith reproduce in Fig. 479 an ohm-meter circuit for general connec-

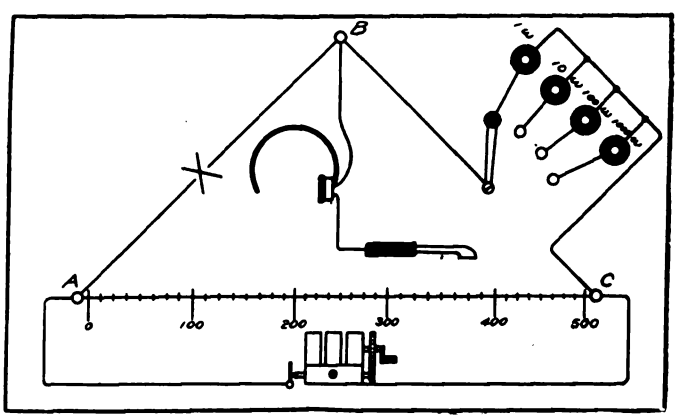

Fig. 479.

tions. If you wire up your ohm-meter in accordance therewith you will, no doubt, obtain satisfactory results.

RECEIVER ADJUSTMENT.—(480.)

Why are paper rings placed between a receiver diaphragm and the cap?
L. N.

Paper rings are used to aid in the adjustment of the receiver. In some of the old style apparatus the receiver magnets were fastened to the end of the case when the cords are attached. Quite frequently the expansion of the magnets is greater than that of the case, and consequently the diaphragm is brought too close to the magnet. The rings are used to increase the distance so as to secure the best results.

Rings are also used when the cap does not hold the diaphragm tightly; in this case they should be placed between the cap and the diaphragm. When a receiver reaches this point, necessitating the use of rings, it would be much better to take it out, as it is almost impossible to secure good results.

IMPORTANCE OF KNOWLEDGE OF TRAFFIC CONDITIONS.

WE desire to draw the attention of the men whose duty it is to manage and superintend telephone plants to the series of articles now appearing in THE AMERICAN TELEPHONE JOURNAL upon traffic. It is safe to say that no department of telephone exchange operation requires more attention than the one termed traffic, and it is also quite true that except in the case of the larger companies there is none so little understood. The prime reason for this is perhaps to be found in the fact that its details and requirements have not been considered except in a very general way, and consequently the invaluable information which a study of the subject contains is rarely discovered, if ever thought of. Yet how important it is can be illustrated by using a railroad system as a simile. It is very certain that a general manager of a railroad system who does not apply himself to the details of the traffic will very soon find out that the system is being run on a losing basis; and that, instead of an adequate supply of cars to handle the rush periods at various hours of the day, his lines are overcrowded and his patrons discontented.

The position of the manager of a telephone system is exactly similar. He must be acquainted with the amount of business done over the various lines; he must acquaint himself with the subscribers who use the telephone lines; and he must also know just at what periods the greatest amount of business is being collectively done, so that he may adequately provide operators sufficient to handle the load, and yet arrange it so that there is no waste force. In the articles to which we refer we are giving illustrations which tend to show, under varying conditions, the distribution of the traffic of a telephone system.

When the business of a subscriber warrants the addition of more lines, this should be immediately known to the manager, because it offers additional revenue to the system. Another important point is that quite frequently a business house could use to great advantage a branch exchange. Now, the subscribers' knowledge of the business is limited, and they do not understand why it is that people so frequently complain that they were called up and told that the line was busy. Thus the business house is liable to censure the system, when this condition might have been averted had the manager posted himself upon the traffic requirements of that particular station.

Trunk lines demand that they should be worked to their maximum capacity, and yet not overloaded. This state of affairs can only be discovered through a careful study of the traffic over these lines. If, for instance, the traffic line between two points is busy but one-third of the time, it is very evident that an additional line would be a loss. Contrawise, if the trunk line is worked to its maximum capacity, and necessitates the holding up of messages on account of the lack of facilities, it is evident that a new trunk is required between the two points. The only way this can be readily determined is through a study of the trunk lines' traffic.

We do not believe that the traffic problem can be solved in a day, a week or a month. It is a constantly expanding problem, which demands constant attention; and which, unless handled with a large amount of common sense and executive ability, is liable to prove the Waterloo of any system. Therefore, to those who have the interest of the system at heart it is imperative that their knowledge should not be limited to the operation of a certain line, or to the details of the construction of the system; but it should include every detail, from the simplest arrangement to the most complicated problem of traffic.

AN IMPORTANT DEPARTMENT OF TELEPHONY.

We earnestly request that all managers give this series of articles their close attention, as we fell certain it will open up a new field and broaden ideas, which will eventually lead to the most gratifying results.

THE NECESSITIES OF A TELEPHONE PLANT.

PAGES could be written of the necessary details to be looked into and considered in the matter of exchange equipment and then not cover the field in more than a cursory manner. The part that makes it still more difficult to lay down a set of general ideas is that no two systems are similar, each and every one requiring special attention. Where party line service is given there are the details of operation to be considered, the various types of this type of apparatus on the market should all be investigated with a view to selecting the one which most nearly fits the requirements of the service. In determining the type of switchboard the probable growth of a system should be taken into consideration, so that a provision may be made for future expansion which shall allow of the additional equipment being installed with the least delay to operation of the plant and at the lowest cost.

When a plant has to be reconstructed because of lack of foresight on the part of its original designers, the cost of such work is far in excess of what would have been necessary where the engineering details had been properly worked out in the start. There is no business which insures such steady growth as a telephone system which is properly designed with a view to economy in operation and that is managed by an efficient force.

Experience has shown that unless the executive heads are men who thoroughly understand the intricacies of the business, the results will not be satisfactory. This point was strongly brought forth by Charles Russel, who said in an address before the Pennsylvania State Convention:

"There are three officials who must work in harmony—the engineer, who provides an equipment of the highest efficiency and is alert to secure for the public the best transmission, either local, toll or long distance; the superintendent of maintenance, whose duties are to keep the equipment in perfect working order, and the traffic manager, who handles the business for whom all others are providing a means for accomplishment."

These remarks cover the general ideas very thoroughly. For success everything about a telephone system must be properly designed, every detail of construction must be carried out with a view to securing the best possible results, and every person concerned in the plant's operation must be capable, and not only capable, but have a direct interest in the welfare of the company.

In summing up, the following points are evident as absolutely necessary to success: First, good apparatus and construction, for without it the best force in the world would be unable to secure results; secondly, a high grade of employees, that is, men and women who can appreciate the responsibility of their positions and who will work to show their ability; and, last but not least, harmony among all employees. With these qualities abundant, any telephone plant must succeed, and since the Independents have, as a general rule, considered all these cardinal points, there is no reason why they should not continue to enjoy the prosperity so well deserved.

The Telephone in the Courts

Conducted by A. H. McMillan.

Readers are invited to submit questions on any point of Telephone Law. They will be answered and explained on this page.

INTERFERENCE BY HOUSE MOVING.

We have several exchanges in Iowa and have been troubled a great deal by parties moving buildings through the streets in our exchange towns. In some cases they do not even notify the telephone company that they want to get through, but go ahead and get through and break down the wires. We have franchises in all the towns. What can we do to protect ourselves or have there been any Iowa decisions in this matter? N. T. Co.

WHILE there have been no Iowa decisions upon the subject, the law is well settled that house movers have no right to break down wires without making compensation to telephone companies. It was held in Northwestern Telephone Exchange Company v. Anderson (N. Dak.), 98 N. W. 706, that the franchise of the company constituted a contractual relation between the company and the city, which became a vested right that could not be impaired by subsequent action of the city licensing defendant to move a building through the streets. Said the court in Williams v. Citizens' Railway Company, 130 Ind. 71, 29 N. E. 408, 15 L. R. A. 64, 30 A. S. R. 201: "Where a right to use a street is acquired pursuant to statute and under a license from a municipality, it is in the nature of a contract right, and the municipality itself cannot destroy or materially impair it. . . . It is undoubtedly true that all such rights are subordinate to the paramount power, usually denominated the 'police power,' for that power cannot be annihilated by contract. . . . It would violate the plainest principles of law to permit an individual citizen to confiscate or destroy the property of a corporation which has assumed to exercise rights under the laws of the State, and to which the officers of the government have given recognition by granting it the use of the streets of the city. . . . The appellants in this case are not asking to be allowed to make an ordinary use of the streets of the city. They are, on the contrary, asking that they be permitted to use the streets in an extraordinary mode, and for an unusual purpose. . . . It would be strange, indeed, if large buildings could be moved along the thronged streets of a city without control or restriction, and it would be equally strange if the owner of a building could destroy the property of others in order to enable him to move his building from one place to another."

Your remedy for a violation of your right of immunity from house movers would be either an injunction to restrain interference with your wires or a suit for the damages inflicted by the interference. In N. Y. & N. J. Telegraph Co. v. Dexheimer, 14 N. J. Law J. 295, the defendant was a licensed house mover, and in moving a house cut the wires of the defendant's system. Suit was brought for damages and the jury was charged that the defendant was liable if he cut any wires that were put up and maintained in accordance with the city ordinance under which they were put up, and ordered damages assessed in plaintiff's favor for such as were thus maintained and were cut, and these only.

See also Millville Traction Co. v. Goodwin, 53 N. J. Eq. 448, 32 A. 263; Penn. Tel. Co. v. Varnau (Pa.), 15 A. 624; Day v. Green, 4 Cush. 433; Graves v. Shattuck, 35 N. H. 257, 69 A. D. 536; Townsend v. Epstein (Md.), 49 A. 629, 52 L. R. A. 409, 86 A. S. R. 441.

IMPLIED LICENSE.

A TELEPHONE company erected telephone poles along a highway without the consent of a person whose land abutted upon the highway and whose title extended to the center thereof. The land-owner permitted the telephone company to occupy the highway for some time and then attempted to force the company to remove its lines. It was held that the company's occupancy of the premises after knowledge of the entry by the land-owner was an implied license which, having been initiated by a trespass, did not confer on the telephone company an easement to maintain its poles, and as such was subject to revocation at the will of the owner of the land.

It was also held in this case that the grantor of the land-owner was entitled to maintain ejectment to oust the telephone company from the use of the highway and was not required to bring a suit in equity in which its equitable rights, if any, might be ajudicated.

Little *vs.* American Telephone and Telegraph Co. 89 N. Y. S. 136.

ENFORCEMENT OF CONTRACT.

AS part of the consideration for the release of a right of way to erect and maintain a telephone line along a public highway adjoining the premises of Oliver M. Foster and Edward E. Foster in Jackson county, Ind., Charles Leininger, the owner and operator of a telephone exchange in Seymore, Ind., agreed to place in the residences of each of the Fosters, and also of John Q. Foster, a telephone and connect same with the Seymore telephone exchange. The company was to maintain and keep in good repair said telephone for the period of five years and each of the Fosters was to pay therefor a dollar per month. It was further provided that J. Q. Foster was to erect, at his own expense, suitable telephone poles upon which to attach telephone lines from the city to his residence. Leininger failed to supply J. Q. Foster with a telephone and he brought suit for damages. In the Circuit Court a demurrer to the complaint was sustained, but the Appellate Court of Indiana refused this judgment.

One of the objections to the complaint was that it was not enforcible at the suit of the appellee because it was not averred that he had erected at his own expense poles upon which to string wires. It was argued that the erection of the poles was a condition precedent to his right to demand the placing of the telephone in his house and the connecting it with wires leading to the exchange. The Court held that this would be a correct statement of the law if appellee had performed the conditions of the contract on his part. It is a firmly established rule of law that it is unnecessary to allege performance and an offer to perform on the part of the plaintiff when it is shown that the defendant has repudiated it and denies liability under it.

Another objection of the plaintiff was that the contract upon which the complaint was based was not mutual. In this case the plaintiff was not a party to the contract and his rights, if any, exist by virtue of the fact that defendant agreed with others upon certain conditions to place a telephone in his house and connect it with the telephone exchange. The Court held that this did not change the facts for the rule of law is that a contract between two parties made for the benefit of another may be enforced by such other party although he was not privy to it and no consideration passed from him to the party bound. Neither is it necessary for the plaintiff for whose benefit the contract has been made to aver an acceptance of the contract, for this is implied by bringing a suit upon it.

Foster *vs.* Leininger (Ind.) 72 N. E. 164.

CITATIONS OMITTED.

CITATIONS were accidentally omitted in the article entitled "A Pole an Appliance, not a Place," in our number of November 26, and in the article headed "Illegal Use of a Telephone," in the issue of December 17, of this year. The case referred to in the first article is Britton v. Central Union Telephone Co., 131 Fed. 846; the other case is Godwin v. Carolina Telephone & Telegraph Co. (S. C.), 48 S. E. 636.

IN THE OPERATING FIELD.

GOOD SHOWING OF RED RIVER VALLEY COMPANY.

THE annual meeting of the Red River Valley Telephone Company was held recently at Buxton, N. D., 200 of the 500 stockholders being present. The following officers were elected: President, T. J. Smith; vice-president, P. M. Paulson; secretary, treasurer and general manager, F. H. Hagen. Directors—T. J. Smith, S. K. Knudtson, O. J. Sorley, Theo. E. Ostlund, C. G. Thoreson, D. M. Paulson, S. H. Hagen, Lewis Thompson, Walter Christen.

The company declared a dividend of 12 per cent. and transferred a nice surplus to the reserve fund. The company has a paid-up capital of $65,000.

The company has 1,050 telephones in use among farmers and business men in Grand Forks, Traill, Steel and Nelson counties, North Dakota, and Polk county, Minn.

KINLOCH IMPROVEMENTS AT ALTON, ILL.

A SERIES of improvements which will amount to over $40,000 has been inaugurated by the Kinloch Telephone Company at Alton, Ill. Large, heavy cables will be installed that will extend all over Alton, Upper Alton, North Alton and parts of Yager Park. The latter has never been reached before by the Kinloch company. These cables are being installed in order to give more facilities for the growing business in this city. The system in Middletown will be improved by the placing of these cables in that vicinity. The entire work will take about three months to complete, states Local Manager W. H. Reed.

THE MEADVILLE (PA.) TELEPHONE COMPANY TO EXTEND ITS SYSTEM.

THE Meadville Telephone Company, which has in the past made extensive additions to its toll and long-distance service, is at present contemplating new additions which will give its subscribers a greatly increased territory. Recently connections were completed with Franklin, Oil City, Cochranton, Titusville, and Pittsburg. The circuits, both local and long-distance, are metallic and the instruments of the latest improved types.

The growth of the company's business has been very rapid, there now being 1,200 local subscribers. In addition to these, free service is given with the exchanges at Conneaut Lake and Harmonsburg, and also with about 65 farmers in the vicinity of Watson's Run, who are thus, to all intents and purposes, on the local exchange list.

NEW TELEPHONE COMPANY OF INDIANAPOLIS TO ERECT NEW BUILDING.

THE New Telephone Company, of Indianapolis, Ind., has recently ordered plans prepared for a new exchange building to occupy the present site in Meridian street. The specifications call for the erection of a fireproof structure to cover the entire lot, 50x195 feet. The building will be erected in two parts; the first to be four stories high, and will be utilized for the switchboard and auxiliary apparatus. When completed a large amount of new equipment will be installed to take care of the phenomenal growth of the company's business. The old building will then be torn down and an eight-story structure erected, which will contain the offices of the company and operators' quarters, such as dining hall and rest room.

This company has enjoyed an extraordinary growth during the past year, having added since January 1,856 telephones to the list. To accommodate this increased patronage the company has had to enlarge the capacity of tne switchboard 25 per cent.

S. P. Sherrin, the president of the company, states that there are 166,000 Independent telephones in Indiana, and that of these 84,000 are within a radius of fifty miles of Indianapolis.

HOME COMPANY, OF RICHMOND, IND., GIVES FREE TOLL SERVICE.

THE Home Telephone Company, of Richmond, Ind., upon the completion of its new switchboards recently, gave its subscribers free long-distance telephone service over the U. S. Telephone Company's lines in its Ohio territory. The above territory includes practically all of Ohio and parts of Michigan, Pennsylvania and West Virginia. The company has just installed new and up-to-date toll swithboards and now has entirely separate apartments for its long-distance business. The boards installed are the latest and best type and place the company in excellent position to take care of its long-distance business, as neither money nor time was spared in its effort to make its toll system as perfect as possible. Work is now in progress on additional copper toll lines between Richmond and Indianapolis which will materially improve the service and facilitate prompt handling of toll business going west.

TO TELEPHONE FROM MOVING TRAINS.

IT is reported Aloysius S. Peshong, of Dunkirk, N. Y., has practically completed a system of telephoning from moving trains. He says by his method it is possible for a man to step to the end of a moving car and converse with his family as though in his office in the city. He also says trains can be dispatched as safely by his invention as by telegraph. Among the other advantages Mr. Peshong claims his system will have over the telegraph is the fact that the train dispatcher can carry on a conversation at any time with the engineer, and knows exactly what time he is making between stations and could figure accordingly in case of a breakdown to the locomotive or train. He is confident that the railroads will adopt the new system and declares that wrecks on single track road in the future will be reduced to a minimum.

NEW U. S. CIRCUITS.

THE United States Telephone Company is making great headway with the construction of its new lines in Ohio. These circuits are being put up in the most approved manner and consist of heavy copper lines which will be able to handle the business under the most exacting conditions. New lines are being built from Columbus to Toledo and to Plain City and Marysville, which will greatly aid the growing demands of the system.

CONNECTING LINES OF CITIZENS' COMPANY, OF ST. JOSEPH, MO.

THE connecting toll lines of the Citizens' Telephone Company at St. Joseph, Mo., now connect with towns and cities all over Ohio, Indiana, Kentucky, Illinois, Kansas, Iowa, Nebraska, Missouri and some places in Michigan.

New toll lines are being extended into Oklahoma, Indian Territory and Arkansas, on the south and southwest. The latter lines will be giving service in about ninety days; and in about

Digitized by Google

sixty days connections will be made with Sioux City, Iowa; Sioux Falls, S. D.; St. Paul and Minneapolis, Minn., and the hundreds of intermediate towns and cities.

The company has recently been connected with Lincoln and South Omaha, Neb., together with cities and towns in the vicinity of the two latter places.

The Citizens' Telephone Company is stringing new cables into the suburbs of the city, and will continue to do so until the entire city is practically covered. During the next ten or twelve months they will put into use sufficient cable to accommodate from 3,000 to 3,500 patrons, in addition to those they now have.

Besides the city lines it has several hundreds of farmer and country town subscribers, to whom the city subscribers can talk free.

ANOTHER INDEPENDENT STATEMENT.

THE New Ottawa Telephone Company, which operates a system in the town of Elmore, Ohio, has recently issued a comparative statement for the years 1903 and 1904, which is given herewith.

Attention is drawn to the rate of interest paid on dividends,

COMPARATIVE STATEMENT, NEW OTTAWA TELEPHONE COMPANY, FOR 1903 AND 1904.

	For year ending Nov. 1, 1903.	For year ending Nov. 1, 1904.
Gross receipts	$20,706.92	$23,973.67
Expenses	8,981.72	10,806.80
7 per cent. dividend....	8,680.00	8,680.00
Surplus	3,045.20	4,486.87
Net increase	.....	1,441.67

which compares favorably with any paid by the Bell companies. Another noteworthy feature is the amount carried to surplus, which is nearly 50 per cent. greater than for the preceding year.

In view of the fact that the Bell Company has contended that Independent securities were not on a paying basis, this report is timely inasmuch as it tends to refute that statement.

MARYLAND'S LONG-DISTANCE CONNECTION.

THE Maryland Telephone Company will open its Western connections January 4. With these connections completed the Maryland will become a part of a great telephone system covering practically all the Middle Atlantic States and reaching to the West as far as St. Louis and Chicago. Through its connections with the Keystone Telephone Company, of Philadelphia, and other Independent lines ramifying lower Pennsylvania and its connections with Western Maryland Independent companies, the Maryland now has the neighborhood around Baltimore pretty well covered.

Mayor Timanus will be invited to open the Western lines and will speak to the mayors of St. Louis and Chicago to celebrate the opening. Members of the city council, the city and State government, and prominent bankers and business men who have helped to make the Maryland Telephone Company a success will be invited to attend the opening ceremonies and then to partake of the luncheon which will follow.

A NEW FIRE-ALARM SYSTEM.

W. L. DENIO, of Rochester, N. Y., is now demonstrating a new fire-alarm system, which operates over the regular telephone wires either automatically or when rung in by the person discovering a blaze.

A company for the manufacture of the apparatus will be formed within a week or two by H. F. Atkinson, Mr. Denio, C. M. Henderson, B. B. Clark and Frank Bouton, who are interested in the device.

The apparatus consists of a signal box, which is placed near the telephone and connected with the regular telephone wires. From this signal box wires will lead to any part of the building or office desired with thermostats placed at stated intervals, all on the same circuit. These thermostats are so constructed that at the moment they are subjected to more than 150 degrees of heat they collapse, a stout spring drawing a copper bar against the circuit wires, thus allowing a current to pass through, which releases a spring in the signal box and sets the machinery in motion.

Connection is thus made with the central telephone office, the operator being warned of the fire by a series of intermittent flashes of the electric light. This warning of fire cannot be mistaken for anything else, as the operator is able to hear the mechanism of the signal box as it whirrs out its signal.

The system apparently guards against every possible accident. As long as the telephone wires are in working order an alarm is bound to be sent in. The same result is obtained when the telephone is in use, when the receiver is left off the hook or when one of the telephone wires is cut. As long as there is one wire connecting the telephone with the central exchange an alarm will be sent in the moment the flames touch any one of the thermostats.

HULL MUNICIPAL SYSTEM OPENED.

THE Municipal Telephone system of Hull, England, has recently been opened. The system was originally designed for 2,000 lines, but so many subscribers have been secured that it is probable an extension to the switchboard will have to be made in the near future. The plant was designed by Mr. A. R. Bennett, who also has charge of the municipal system in Glasgow, Scotland. Underground distribution to the extent of about 19 miles has been employed. It is noteworthy to remark that the largest cable is reported to contain over six hundred wires. Provision has been made for interconnection with the National Telephone Company's system, there being 120 trunks now employed. Additional connections have been provided for the long-distance lines of the Port-Office Department.

The switchboard was made by the Ericsson Bell Company, of London, and resembles the American type of common battery board.

The rates for service will be, £6 6s. ($30) for business unlimited; £5 ($24) for residence unlimited, and a sliding scale for message rate service.

NEW L. D. CONNECTIONS OF PITTSBURG AND ALLEGHENY.

THE Pittsburg & Allegheny Telephone Company is making rapid progress in the construction of its line from Pittsburg to Butler, a distance of about thirty miles. At Butler the Pittsburg line will connect with the lines of the People's Telephone Company, which has over 1,000 local subscribers. The connection when completed will put the Pittsburg subscribers in close touch with residents of Butler, Kittanning and several other smaller towns north of Pittsburg.

The Pittsburg and Allegheny Telephone Company expects to have its line to Wheeling completed by Christmas time, and also its long line to the West in the best working order. Extra care is being taken in the construction of this line, and very heavy No. 6 and No. 8 copper wire is being strung on the best poles procurable. Through its Wheeling connection the P. & A. company will be able to put its local subscribers in direct connection with Columbus and Dayton, O.; Richmond and Indianapolis, Ind.; and Kansas City and St. Louis, Mo. All these cities have large exchanges and by the through service to the West the value of the P. & A. service to Pittsburgers will be greatly increased.

CHICAGO TELEPHONE COMPANY AGAIN.

IN an opinion on the telephone ordinance of 1899, Corporation Counsel Tolman has ruled that the Chicago Telephone Company shall pay the city 3 per cent. of its receipts from its telephones in the territory annexed after the passage of the ordinance. Between $300,000 and $500,000 is involved. He also held that the company has no right to charge tolls within the city limits, and that the city can compel the company to inclose public telephones in boxes or booths.

IN THE MANUFACTURING FIELD

"SUCCESS LIES IN THE KNOWLEDGE OF OUR TOOLS"

A STREET TELEPHONE PAY STATION.

THE Controller Company of America has recently devised a new coin telephone set, which is shown in the accompanying illustration. It is styled the No. 7 combination, and consists of a cast-iron pedestal, which bolts to the sidewalk or to a bed stone laid flush with the pavement, upon which is mounted a controller encased in an iron box having a self-closing door. The service wires may either drop from the pole and enter the box through a water-excluding gooseneck or may enter from underground through the pedestal. Space does not permit us to discuss at length the possibilities of this method of giving telephone service, except to say that it meets the necessities of a class of pay-station service that has not heretofore been developed.

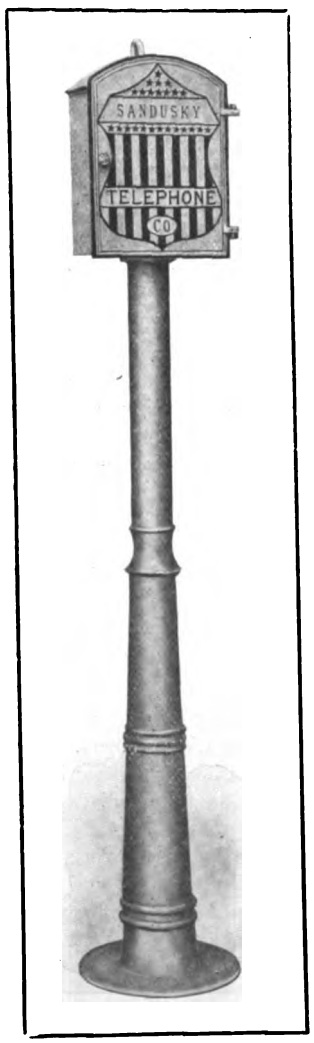

Fig. 1. Controller Co.'s Street Pay Station.

The reason for this new development is obvious from the fact that no apparatus had been specially devised which would be able to fill the various requirements of pay-station service operating under these conditions.

In conjunction with the fire and police service of a city, telephone companies should find no trouble in having the fire and police ordinances so amended as to include this form of communication. By referring to the illustrations a general idea of its practical design can be obtained. Fig. 1 shows the box closed. The design on the front of the door is striking enough to draw instant attention to the fact that it is an Independent pay station and should therefore form an excellent advertisement for a company. At railroad stations the instruments could be placed at any convenient point on the platform and thus be within instant reach of the traveling public. In cases where no arrangement can be made with the railroad company for their installation at the stations, these pay stations could be placed at some conspicuous point near by.

The Controller Company of America is preparing to issue bulletin No. 7, which will very thoroughly describe this type of apparatus and its possibilities from every standpoint. To parties interested the company will be pleased to supply all information, including the preceding bulletins already issued, which describe its telephone apparatus for measured service.

COOK APPARATUS.

ONE of the most novel and interesting advertisements in our last issue was that of Frank B. Cook. The advertisement told, without a word of descriptive matter, a most comprehensive and interesting story of the line of protective apparatus and construction material which Cook makes. It was a surprise to most exchange managers, for there are many who did not realize how complete Cook's line is.

In the advertisement the artist has shown a complete system of protectors, from the central station apparatus to the protector for the subscriber's instrument.

Back of the switchboard is shown a diagram of Cook's well-known No. 444 protector for the central station, the feature of this protector being the self-soldering heat coils. Cook's patented test plug is also shown. Cook has sold about 70,000 pairs of this type of protector in the last six months.

The cable leads out from the central station protector to the office pole. Following it, one's attention is next attracted to the Marlin cable hangers, also handled by Cook. Crossing to the pole which is the pole at the outermost end of the cable, Cook's type S. A. pole cable terminal is shown. From here the jumper wires lead to the cross-arm and are there distributed to the glass insulators.

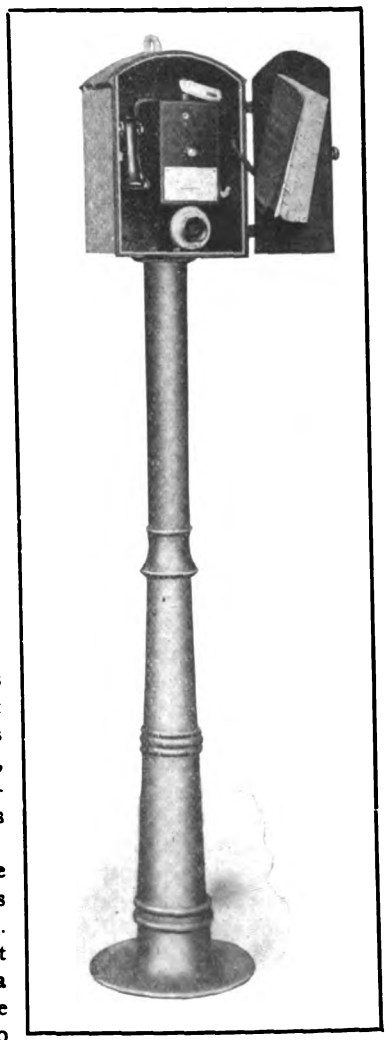

Fig. 2. Showing Interior of Controller Co.'s Street Pay Station.

One drop from the cross-arm leads to the subscriber's instrument, which is protected by one of Cook's type 12-A subscriber's station protectors. Another drop leads to a building, outside of which are shown two different types of Cook's tubular line fuses.

The pole is guyed with a hevy stranded cable, on which is used one of Cook's universal guy clamps. It appears that Cook has passed this way recently, for his card is seen hanging from one of the steps on the pole.

The cross-arms on the pole are supported by Cook's tubular cross-arm braces. On a pair of line wires at the office pole is shown a transposition in which are used two of Cook's Type 00 test connectors. On one of the line wires at this pole is also shown a sleeve connector for making a splice in the wire, this also being handled by Cook.

THE MOUNTAIN STATE ELECTRICAL COMPANY, Wheeling, W. Va., has recently received orders from some of the largest telephone companies for its Hall type D cable terminal with distributing ring. This terminal has been specially designed for underground installations and possesses some features not found in others. Each pair is provided with absolute lightning protection and is mounted on a hard rubber strip. Cross connections can be easily made and the wires neatly arranged in a better way

NEW PROTECTIVE AND CROSS CONNECTING APPARATUS.

THE Swedish-American Telephone Company has recently put on the market a new protective and cross connecting equipment that is meeting with the general approval of all telephone men, judging from the heavy demand that there has been for it. There has always been an urgent need for good equipment of this character. The Swedish-American Telephone Company has gone forward another notch in the art of telephony in designing this new apparatus.

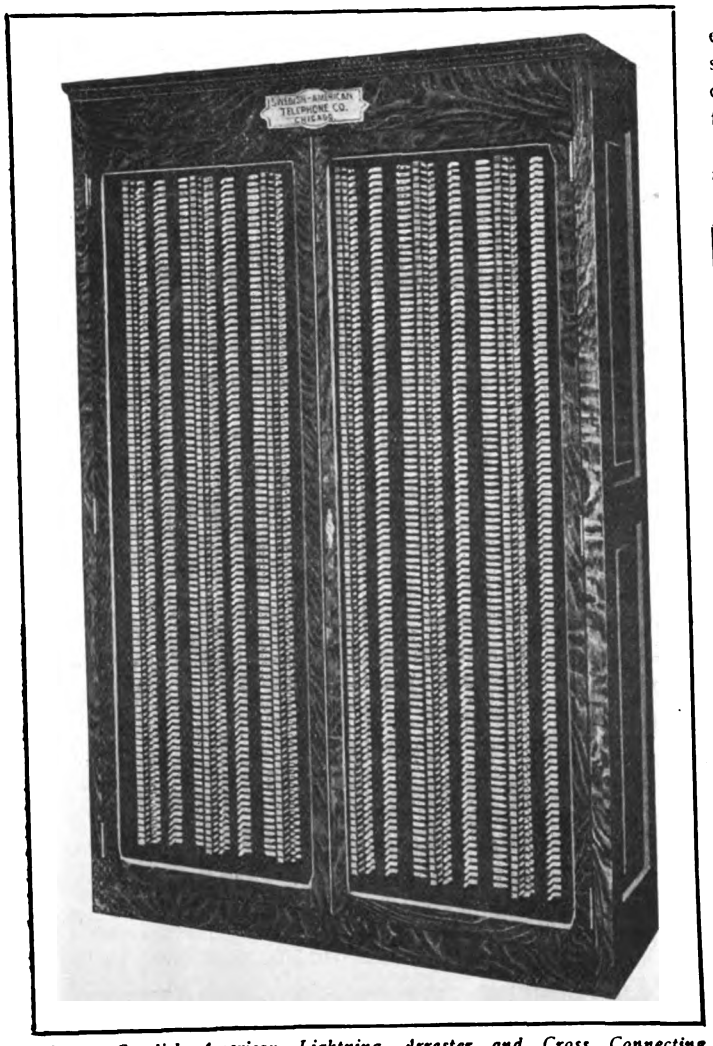

Fig. 1. Swedish American Lightning Arrester and Cross Connecting Cabinet.

Fig. 1 represents a combination carbon and fuse lightning arrester and cross connecting cabinet with a capacity of 300 metallic lines. The lightning arresters and cross connecting clips are mounted on three-ply, thoroughly seasoned maple strips, each strip having a capacity of 100 single lines. The boards are so arranged that all the cross connecting is done in the back, and is consequently hid from the front view. They are mounted in a highly finished quarter-sawed cabinet, as illustrated. The cabinets are furnished in three different sizes, 300, 200 and 100 metallic lines. It is not necessary to get the cabinet complete to its full capacity, as an additional strip can always be mounted in the cabinet as needed.

Fig. 2 shows the method of connecting metallic and grounded lines and also gives dimensions of board. This equipment adds materially to the appearance of central offices, as well as providing a simple, inexpensive method of protection and an accurate record of the different cable lines, each strip being numbered in such a way as to enable one to instantly locate the line desired and make the cross connections in a thorough and complete manner. Heretofore cross connecting wires have generally been seen on the front side of the board where the clips were mounted, and in a number of cases they have been the cause of confusion and mistakes.

The above described lightning arrester and cross connecting equipment has the features of being very compact and at the same time simple and easy to work on. By opening the cross door of the cabinet the operator can instantly find a certain line fuse, thereby saving considerable time in locating trouble.

The carbons in the lighting arrester are of a grooved pattern and easy to remove and replace. The little clips holding the line fuses are arranged so as to create a strong tension, thereby pro-

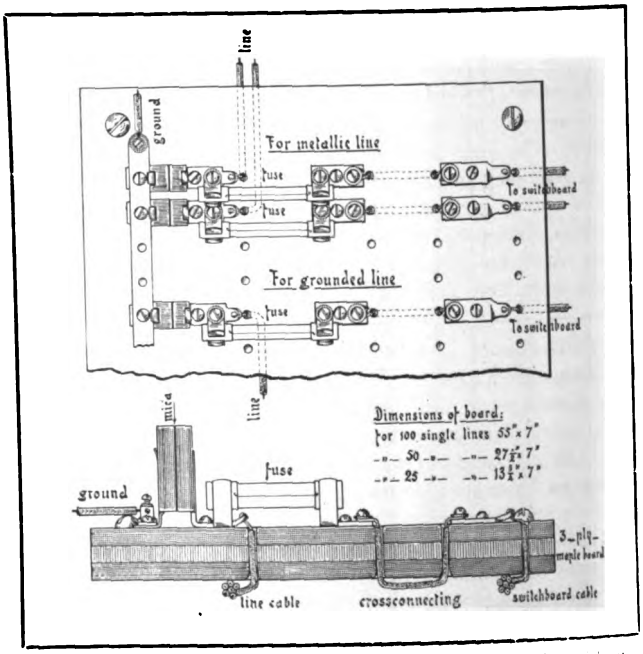

Fig. 2. Circuits for Cross Connecting in Swedish American Cabinet.

viding a good contact. They are made from strong German silver and will not lessen their tension. The clips holding the fuses are slightly bent, thereby giving the fuses an inclined position, which will prevent dust from settling on the fuses.

Other particulars and prices will be gladly furnished on application to the Swedish-American Company.

FRANK B. COOK, of Chicago, Ill., has recently had three decisions rendered in his favor by the United States Patent Office in interference case No. 23,636, Cook vs. Kaisling, relative to a self-soldering heat coil. July 25, 1904, the department denied Kaisling's motion on leave to amend his preliminary statement. August 11, 1904, the department, upon a rehearing, again denied Kaisling's motion on leave to amend his preliminary statement. August 12, 1904, decision was rendered denying Kaisling's motion to dissolve the interference on the ground that Cook had no right

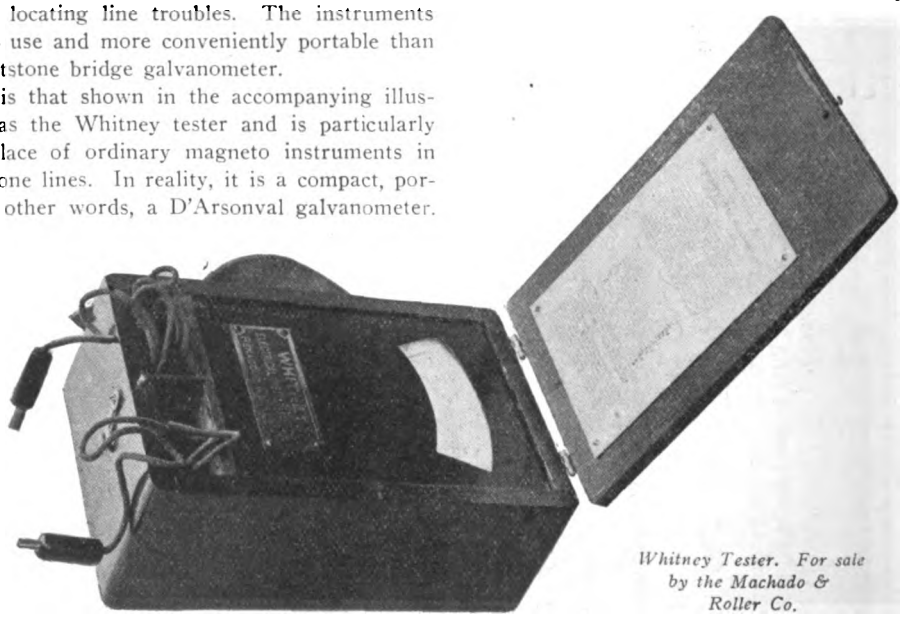
to make the claim, the examiner deciding that Cook alone was entitled to the claim in interference. Limit of appeal expired September 1, and as no appeal was taken, the subject matter defined in the issue remains in Cook's application and must be erased from Kaisling's.

A NEW TESTING INSTRUMENT.

THE Machado & Roller Company, of 203 Broadway, New York, selling agents of the Whitney Electrical Instrument Co., has recently issued an interesting and descriptive catalogue relating to electrical measuring instruments, many of which will be found of considerable utility in telephone work. The catalogue chiefly deals with the various forms of voltmeters and ammeters, embracing all ranges of this form of measuring instrument from the milli-voltmeters and the milli-ammeters, reading to one thousandth of a volt and one thousandth of an ampere respectively, to large central station instruments capable of registering great quantities of current and high pressures. A notable feature of the catalogue is a description of the new forms of the Sage ohmmeter, which telephone linemen will find particularly convenient in locating line troubles. The instruments are much more easy to use and more conveniently portable than any form of the Wheatstone bridge galvanometer.

A novel instrument is that shown in the accompanying illustration. It is known as the Whitney tester and is particularly adapted to take the place of ordinary magneto instruments in making tests on telephone lines. In reality, it is a compact, portable voltmeter, or, in other words, a D'Arsonval galvanometer. It is arranged so that it may be carried either in the pocket or slung over the shoulder. It measures 7½ x 4¾ x 3 inches and weighs about four pounds. These instruments for testing purposes are wound from 5,000 to 25,000 ohms, and are correspondingly sensitive. Each instrument is accompanied by a pair of small dry cells and an adjustable rheostat. The terminals are so arranged that they may be easily used in making any of the well-known resistance measurements.



Whitney Tester. For sale by the Machado & Roller Co.

TELEPHONES FOR SOUTH AMERICA.

THE Monarch Telephone Mfg. Co., of Chicago, has just closed an order for two hundred telephones and a large amount of construction material, as well as telephone and switchboard parts, to be shipped to Guayaquil, Ecuador. The instruments are the standard Monarch No. 30 series sets, equipped with the latest devices of the Monarch Company. The company at Guayaquil has succeeded in building up a good business and reports that the native South Americans are enthusiastic users of the telephone, as they can thus talk most outrageously to their worst enemies and still feel moderately sure that a stiletto will not come into play the next instant. The Monarch Company guaranteed that their transmitters would transmit any speech, no matter what the language might be or how it was spoken. Shipment of the apparatus were made about December 20, and the goods will then arrive in Guayaquil about February 5, 1905.

THE GEMMILL TELEPHONE AND MFG. CO., Orrville, Ohio, is manufacturing a "reversed" solid back transmitter, that is meeting with unqualified success. This transmitter is built upon lines which insure the greatest volume of sound without loss of clearness and quality of tone. Its mechanical construction is as nearly perfect as it is possible to be made and leaves nothing to be desired. This firm also manufactures express and toll line switchboards of any capacity, and a party line telephone which is well called the Sampson, on account of the strength of its magneto generator, which makes it one of the best instruments for rural line service so far devised. Central energy apparatus to meet the most exacting requirements has been designed, and so well has it been received that orders from every part of the country are being constantly received. The company believes that it has the most practical apparatus on the market to-day, and therefore hopes to hear from every reader of this paper. Prices and all other information will be furnished upon request.

THE HADLEY WILLIAMS COMPANY, of Pittsburg, Pa., is placing on the market two new devices for telephone users which are unique. One of them is termed a muffler and consists of a cap which fits over the mouthpiece of a transmitter. Its use is to prevent dust getting in and also to prevent any sound being conveyed over the line that is not desirable when the receiver is off the hook. The other novelty consists of a spring wire clip to hold the receiver when it is desired to call a party to the telephone. This clip fastens over the transmitter and forms a secure holding place for the receiver, thus preventing the wear upon the cords which occurs when the receiver is allowed to hang down. The company will be pleased to furnish further information and prices upon request.

THE CHICAGO WRITING MACHINE COMPANY, Chicago, has recently doubled its manufacturing plant. It has added considerable new machinery, including a full complement of new adjustaphone tools, dies, etc., and the company takes pleasure in announcing that it is now prepared to handle orders of any magnitude quickly and satisfactorily.

The phenomenal sale of this apparatus, and the universal approval and satisfaction that it has met with by telephone companies throughout the country, indicate that the adjustaphone is a most profitable investment. The manufacturers claim that this apparatus has long since passed the experimental stage, and although only a little over a year on the market, has been standardized and adopted by thousands of telephone companies in the United States, Canada and Europe.

The company is making an exceptional offer on two types of the adjustaphone and will be glad to send one on free trial.

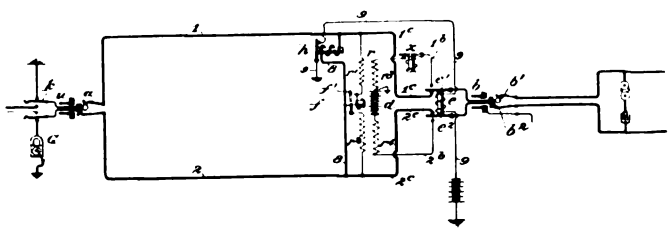
TELEPHONE PATENTS

RINGING CIRCUIT FOR TELEPHONE TRUNK LINES.

E. H. Smythe, of Freeport, Ill., patents (No. 774,283) an improved ringing circuit for telephone trunk lines and assigns to the Western Electric Company, of Chicago, Ill.

The object of this invention is to provide a ringing circuit whereby the A operator upon a trunk line or toll line is enabled to ring the subscriber without the intervention of the B operator. The essential features of this circuit are shown in the accompanying illustration. The ringing generator *G* is connected with the trunk line by a ringing key *k* and plug *u* inserted in the spring jack *a* of the trunk line. At the other end a repeating coil *r* di-



vides the line, the windings *r'* and *r2* being connected with the trunk line conductors *1* and *2*. The windings *r3* and *r4* are connected with the conductors *1b* and *2b*, which lead through the normally closed contacts of an electromagnetic switch *e* to the tip and ring of the plug *b*. Battery *d* is in a bridge between the windings *r3* and *r4*, and windings *r'* and *r²* can be connected by contact *f'* of relay *f*. Relay *h* is permanently connected in a bridge *8* of conductors *1 2* and must have sufficient impedance so that it will not shunt the talking currents, but is adapted to respond to ringing current. When excited this relay closes circuit *9* from battery *d* through magnet of electromagnetic switch *e* which has two armatures *e'* and *e2* connected to tip and ring of contacts *b'* and *b²*. Normally these are in contact with the extension of conductors *1b* and *2b* leading from the windings *r3* and *r4* of the repeating coil. When the magnet of the switch is excited by closing local circuit *9* by the relay *h* the armatures *e'* and *e2* are closed as shown cutting off the battery and repeating coil and connecting contacts *b'* and *b2* to the extension *1c* and *2c* of the trunk conductor *1* and *2*, thus a through conductive circuit is provided from one end of the trunk line to the other, independent of the repeating coil, and then the A operator may ring the distant subscriber in the usual manner, being provided with any desired form of ringing key or ringing current.

SUBSTATION SIGNAL SYSTEM.

J. W. Fouche, Ryan, Va., patents (No. 774,059) a substation signal system, and assigns two-thirds to H. B. Hutchison and C. A. Hutchison. The object of this invention is to provide an improved signal for telephone substations. The inventor provides an electromagnet which carries a vibrating armature. This electromagnet is sensitive to alternating currents, and if actuated thereby, its armature is thrown into vibrations in a manner similar to the ordinary vibrating bell. This armature carries contacts which are in circuit with the local battery and so arranged as to act as a pole changer, and consequently the device may be used to operate a signal that is actuated by direct current in any of the usual ways.

ADJUSTABLE SUPPORT FOR TELEPHONE RECEIVERS.

G. W. Sebastian, of Ashland, Ky., patents (No. 775,254) an improved support for telephone receivers, and assigns one-half to J. Leicht, of Ashland, Ky. The object of this invention is to provide a support for a telephone receiver so that it may be secured in some fixed position with reference to the transmitter in such a way as to suit the ear of the one using the telephone. The inventor provides a rod which, by means of a clamp at its lower end, may be secured to any portion of the telephone set. The upper end of the rod carries another clamp for the purpose of holding the receiver. These clamps are adjustable, so that the receiver may be fixed in any desired position.

PARTY LINE TELEPHONE SYSTEM.

C. Vollmer, of Winsted, Minn., patents (No. 774,543) an improved party line system. The object of this invention is to provide an improved party line telephone system in which any subscriber may call any other subscriber on the line without notifying any other station and to provide a busy signal which shall indicate to all other stations that the line is in use.

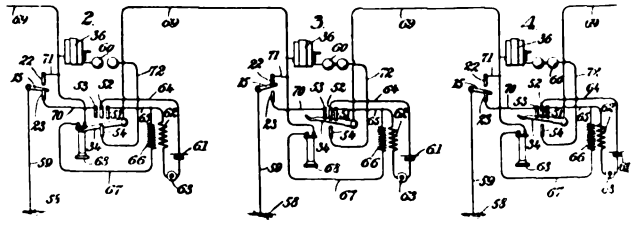
The invention is a complicated one employing a clock-work mechanism for operating the various contacts at each substation, and cannot be adequately described in an abstract. Those interested are recommended to secure a copy of the original patent.

AN ATTACHMENT FOR PARTY LINE SYSTEMS.

W. A. Shackleford, of Lexington, Ga., patents (No. 774,608) an improved attachment for party line systems. The object of this invention is to produce an attachment for party line substations whereby any subscriber other than those engaged in conversation is prevented from hearing the conversation between those using the line; and to enable any pair out of several stations that possibly may be connected to converse independent of all others, and secure from interruption.

In the accompanying illustration the circuit is shown, three stations, numbers *2*, *3* and *4*, being represented, numbers *2* and *4* being assumed to be in conversation.

The attachment consists of a pair of contacts *22* and *23*, a lever *15*; the drawing shows a grounded circuit, but a metallic line may be substituted for the ground without changing results. To make a call, any subscriber actuates his magneto *36*, sending current over line *69*, switch hook *34*, contact *54*, conductor *72*, bell *60*, generator *36*, conductor *69* to the station, and in that station through a similar circuit. Suppose No. *4* calls No. *3*, and *3* has answered; after No. *3* removes the receiver No. *4* would force lever *15* upwards and complete circuit from No. *2* through wire *71*, contact *22*, lever *15*, conductor *59* to ground. The talking circuit is now complete between the two stations but no further, and is from ground *58* at station *4* through *59*, lever



15, contact *23*, wire *70*, switch hook *34*, contact *51*, conductor *65*, secondary *66*, conductor *67*, receiver *68*, conductor *69* to station *3*, switch hook *34* at this station to contact *51*, conductor *65*, secondary *66*, conductor *67*, receiver *68*, conductor *71*, contact *22*, lever *15*, ground wire *59* and return. The stations *3* and *4* are thus connected and the others excluded. If two other stations, say *2* and *4*, are talking, and No. *3* removes his receiver, the circuit through No. *4* would be grounded, and therefore the conversation interrupted and the parties notified thereof.

THE WEEK'S MESSAGES

FINANCIAL.

CHICAGO, ILL.—The directors of the Strowger Automatic Telephone Exchange have declared a dividend of 50 cents a share, payable on January 2, to stock of record of December 22.

UNIONVILLE, IND.—The Unionville Telephone Co. has increased its capital stock from $1,300 to $13,000.

FRANCHISES.

OCEAN PARK, CAL.—The City Council has granted Louis Blankenhorn a franchise for the Home Telephone Co.

KINGSTON, ONT., CAN.—The City Council has granted the Kingston Telephone Co. a five-years' franchise. The company will erect a $30,000 building.

OTTAWA, CAN.—Application will be made under the name of the Northwestern Telephone Co. to construct and operate telephone lines throughout Ontario, Manitoba and the Northwest Territory in the Dominion of Canada.

GOWRIE, IA.—J. F. Nordin has been granted permission to erect and maintain poles and lines in the town of Guthrie.

CULIACAN, MEX.—Oscar Braniff, of the City of Mexico, has applied for a franchise to put in a telephone system at this place.

VENTNOR, N. J.—The City Council of Ventnor City has granted to the Atlantic Coast Telephone Co. a franchise to erect poles and string lines in the streets for telephone service.

NIAGARA FALLS, N. Y.—The Niagara Co. Home Telephone Co. has made application to the Common Council of North Tonawanda for a franchise to distribute electricity for lighting, heating and power purposes. They will use their own pole lines for the distributing cables.

SPOKANE, WASH.—Charles E. Sumner, representing the Empire Electric Co., of Toledo, O., has applied for a thirty-five-year franchise and, if granted, will install a system costing $300,000.

WESTON, W. VA.—The Peoples Telephone Co. has applied for a franchise in this city.

ELECTIONS.

WINDSOR, ONT., CAN.—The Ontario Independent Telephone Co., at a recent meeting, organized with the following officers: President, John H. Connelly; vice-president, James H. McRae; treasurer, F. J. Lawrence; secretary, A. D. Prosser; general manager, C. W. Taylor; assistant general manager, P. T. Shesley. The directorate consists of the foregoing officers and J. R. Brooks and Mayor Brault, of Amherstburg. The company will install an automatic exchange system and will commence work immediately on its lines throughout Essex county, beginning at Amherstburg. Over 400 subscribers have already been secured.

MIAMI, FLA.—The Miami Telephone Co. has elected the following officers: G. C. Frissell, president; H. C. McCown, secretary and treasurer.

BLOOMINGTON, ILL.—The McLean County Telephone Co. has elected the following officers: F. Y. Gamilton, president; W. H. Johnson, vice-president; Henry Thobro, vice-president; George Burr, treasurer; E. C. Martens, manager. A dividend of 7 per cent. was declared.

CARLISLE, IND.—The Carlisle Co-Operative Telephone Co. has elected the following directors: Claude A. Ellis, John Whipps, and Thomas B. Hart.

FORT WAYNE, IND.—At the annual meeting of the Home Telephone Co. the following officers were elected: President, Charles S. Bash; vice-president, John B. Reuss; secretary and manager, William L. Moellering.

GRINNELL, IA.—At a recent meeting of the stockholders of the Interior Telephone Co. the following board of directors was elected: J. F. Wilson, W. S. Hendrixon, E. A. Marsh, J. P. Lyman, C. W. H. Beyer, M. Rew and C. R. Clark. After the stockholders' meeting was adjourned the board of directors met and elected the following officers: President, E. A. Marsh; vice-president, J. F. Wilson; secretary, W. S. Hendrixson; treasurer, C. W. H. Beyer. The plant is in first class condition and the company has made extensions during the present year to the value of $2,000. The company expects to be able to pay a dividend of 10 per cent.

KALONA, IA.—The Kalona Mutual Telephone Co. held a meeting recently for the election of officers and other business. Mr. Rawson was elected president; John Durst, treasurer; U. G. Smith, secretary; Dr. Kisor, W. G. Brooke, Dr. Allen and Harry McCully, directors.

LEMARS, IA.—The LeMars Telephone Co. has elected the following officers: A. C. Colledge, president; I. S. Mayhin, treasurer and counsel; A. C. Colledge, L. N. Dalton, F. A. Post, I. S. Mayhin and E. Dukenaven, directors.

LINCOLN, NEB.—The Lincoln Telephone Co. at a recent meeting elected the following officers: C. J. Bills, president, A. W. Field, vice-president; F. H. Woods, secretary; A. C. Faulkner, treasurer.

ALBANY, N. Y.—The Independent Union Telephone Co. has elected the following officers: Samuel B. Rawson, president; Irving H. Griswold, vice-president; Theodore M. Brush, secretary and treasurer.

COHOES, N. Y.—At a recent meeting of the stockholders of the Cohoes and Waterford Home Telephone Co. it was decided to increase the number of members of the board from eight to eleven, and P. H. Andrae, of Cohoes, and F. H. Sudro and T. M. Brush, of Elyria, O., wore elected members of the board. It was also decided to put in an additional cable in certain parts of the city where the lines already erected are in use and more subscribers waiting.

ANDOVER, PA.—The Andover Electric Telephone Co. at their annual meeting elected the following officers for the ensuing year: N. H. Bishop, president; William Webb, vice-president; J. H. Hipple, secretary; E. Harmon, manager.

SALIX, PA.—At a recent meeting of the Salix Telephone Co. the following officers were elected: President, A. S. Hoffman, vice-president, W. R. Foster, secretary and treasurer, Louis Hostetler.

COMBINATIONS.

FREEPORT, ILL.—The Badger State Telephone Co. has purchased the Crosby & Blaisdell Telephone Co., and will take possession at once.

BLOUNTSVILLE, IND.—The Blountsville Telephone Co. has sold its plant to the Cambridge City Co. Mr. Lamb is president of the new company.

LIBERTY, IND.—The Liberty Telephone plant has been sold to James Davis and others for $30,000.

ST. PETER, MINN.—Stockholders of the Nicollet Co. Telephone Co. have voted to purchase for $35,000 the St. Peter Telephone Co. from James Bennett.

OLEAN, N. Y.—Mr. A. V. Hunt, of Olean, has purchased the Home Telephone Co., of Port Allegheny. He will extend the wires to Smethport and Coudersport.

PARK RIVER, N. D.—Henry Wilson, of Wymbledon, has purchased the telephone system from Noxon and Oglesby.

MADISONVILLE, TEX.—The Madisonville Telephone Exchange has been purchased by Messrs. A. B. Foster and H. D. Hunter, who are now owners of the local exchange. It is understood that extensive improvements are contemplated by Messrs. Foster and Houston.

NEW COMPANY NOTES.

RICHIBUCTO, N. B., CAN.—The Richibucto Rexton Telephone Co. has been incorporated with a capital stock of $20,000. A. B. Carson, R. O'Leary and others are the incorporators.

HASKELL, I. T.—The Haskell Telephone Co. has been incorporated with a capital stock of $10,000.

JANSEN, IA.—The Jansen Telephone Co. has been incorprated with a capital stock of $10,000.

WATERLOO, IA.—The Warren Township Telephone Co. has been organized. August Nolfe is president, W. Wendt vice-president.

BENTLEY, KAS.—The Peoples' Telephone Co. has been incorporated with a capital stock of $1,500.

ERICSSON TELEPHONE CO.
Mfrs. and importers of Switchboards, Telephones, and Telephone Supplies.
298 Broadway, New York

Will you ever again buy cables as cheap as now?

Not unless copper takes a long drop, and none of us look for that. On the present copper market we are selling cables way below what we should. That is plain to any man that figures it. Advances are certain, and coming quick.

Big orders are coming in, and more in sight. Everyone needs cable, mostly big lots. Deliveries will be choked as badly as in 1902 and '03. (Remember them?)

Business is already heavier than most buyers think. Those now under cover are wise, because they will get THEIR cables on time, and at present prices.

Profitable contracts for future delivery may be made now if you send us your specifications. Buy enough for all of 1905. It will be good property.

TOLEDO, O. **THE F. BISSELL COMPANY**

Digitized by Google

CHARLESTON, W. VA.—The Eglon Mutual Telephone Co. has been incorporated with a capital stock of $5,000.

HUDSON, WIS.—The Hudson Prairie Telephone Co. has been incorporated.

MISCELLANEOUS.

STUTTGART, ARK.—It is reported that, owing to the rapid increasing in extension of lines and volume of business, a re-organization of the Stuttgart Telephone Co. is to be effected, and subscriptions for stock are being received.

TIFTON, GA.—The Tifton Telephone Co. is making rapid progress in the reconstruction of its system which was recently damaged by fire.

DANVILLE, ILL.—The Vermillion County Telephone Co. has moved into its new building and is now using its new switchboard.

OOLITIC, IND.—The Home Telephone Co.'s exchange at Oolitic was recently destroped by fire.

BURLINGTON, IA.—J. C. Hubinger will commence the manufacture of selective party line systems at an early date. The factory will be located in this city and will be known as the Telephone Construction and Manufacturing Co.

KEOKUK, IA.—It is reported that the Mississippi Valley Telephone Co. is to be reorganized in the near future.

NEW LIBERTY, IA.—The New Liberty Telephone Co., which was recently organized, will construct a telephone system at once.

COVINGTON, LA.—H. H. Smith and Paul Laborde are interested in a new telephone system, which is being organized.

RUSTON, LA.—It is reported that a telephone company will be organized in this town in the near future.

LEWISTON, ME.—The Lewiston & Auburn Telephone Co. is planning to have their system in operation by January 1. It expects to begin business with about 1,700 subscribers in these two cities.

LISMORE, MINN.—The Lismore Telephone Co. has been organized.

KANSAS CITY, MO.—At a recent directors' meeting of the Home Telephone Co. the matter of an extension of the long distance lines out of Kansas City into Missouri, Kansas and Nebraska was the principal business under consideration. Those present were Henry Kichler, Jr., and E. L. Benoist, St. Louis; Arnold Kalman, St. Paul, Minn.; J. J. Heim, Hugh C. Ward, W. S. Dickey, J. J. Swofford and O. C. Snider.

BINGHAMTON, N. Y.—The North Eastern Pennsylvania Telephone Co. has entered into an agreement with the York State Telephone Co., of Binghamton, whereby the stockholders and subscribers of the North Eastern Pennsylvania Telephone Co. will be enabled to connect with Binghamton and Lestershire.

CHURCHVILLE, N. Y.—T. A. Perry and M. J. Bruton are interested in the Churchville Telephone Co. which is being organized.

MADISON, N. Y.—The Madison Mutual and the Richmond-Brewer Telephone Companies will issue a joint directory giving a list of subscribers in Madison, Solsville, Oriskany Falls, Knoxboro, Bouckville, Pine Woods, Eaton, Morrisville, Pratts, Munnsville, and Stockbridge.

CLEVELAND, O.—Cuyahoga Telephone Co. has installed two street pay telephone stations as an experiment.

DEXTER CITY, O.—The Dexter City Southwestern Telephone Co. is planning a farmers' line from Dexter City to Warner.

HAMILTON, O.—W. F. O'Gara is interested in a telephone line which will be built at Sugar Grove.

HOLLIDAYSBURG, PA.—Mr. John B. Elliott has the matter of organizing a new telephone company, with lines running through Frankstown, Catherine, Tyrone, Blair and Logan townships, in charge.

PARKERSBURG, W. VA.—The Mountain State Telephone Co., with chief offices at Parkersburg, has just received a charter from the secretary of State. Following are the incorporators: E. S. Moore, R. S. Moore, E. Browne, S. P. Moore, and P. M. McDonough Jr. These gentlemen own two telephone lines connecting Grantsville with Spencer and Arnoldsburg. They propose making some improvements, and may decide to extend their lines in other directions. The authorized capital stock of the company is $10,000. Grantsville will be the center of the system.

CLINTON, WIS.—A recent fire caused considerable damage to the wires of the Cherokee Telephone Co.

UNDERGROUND.

SANTA MONICA, CAL.—The Home Telephone Co. was granted permission to place its wires underground.

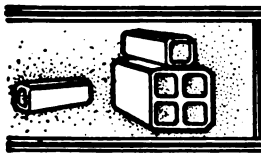
PERSONAL.

GEORGE BENNETT has been appointed manager for the Cumberland Telephone Co. at Lexington, Miss.

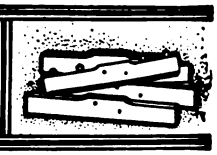
WILLIAM D. MARTIN has been appointed county superintendent for the New York & New Jersey Telephone Co., at Long Branch, N. J.

RAY MUNROE has been appointed district and local manager for the Michigan Telephone Co., at Alpena, Mich., succeeding H. C. Johnson, who has resigned to accept a position in Detroit.

HENRY ROSS has been appointed manager of the Grand Rivers, Ky., Cumberland Telephone Co. office to succeed Mr. Harry Perkins, resigned.



New Construction in the Field



FULLERTON, CAL.—The Home Telephone Co. has commenced the construction of its long distance line from Buena Park to Fullerton, a distance of four miles. It will touch the main Los Angeles-Santa Ana line at the Cox ranch.

RED BLUFF, CAL.—Work has been commenced on the Red Bluff and Paskenta Telephone line. The circuit to Warmouth is being extended to the neighborhood of Paskenta.

MIAMI, FLA.—The Miami Telephone Co. has been organized and will at once commence the reconstruction of its system, using new poles, wire and apparatus exclusively.

ALTON, ILL.—The Kenloch Telephone Co. will expend $40,000 in aerial cable construction in this vicinity.

DES MOINES, IA.—The Mutual Telephone Co. is putting in its new telephones in the vicinity of Des Moines College in North Des Moines. When that part of the new system is completed it will commence working on the down town district. Managers of the company state that they expect to have the down town telephones in by the latter part of December. The company is now in its new building, 1006, 1008, 1010 Grand avenue.

WELTON, IA.—The Delmar Telephone Co. is now extending its lines to Welton where it will connect with the farmer lines. The company has recently run its lines to Maquoketa, also to Elwood, intending to connect the farmers' lines of Delmar with those of Maquoketa, Preston, Welton and Elwood, which will in turn give them access to the Lost Nation, DeWitt and Sabula lines.

WHITEWATER, KAN.—The Whitewater Telephone Co. is completing its line from Whitewater to Wichita. The line will connect with the lines of the Wichita Independent Telephone Co. at that point.

BEAUFORT, MD.—The Peoples Telephone Co. is extending its system through Beaufort county.

MANISTIQUE, MICH.—The Manistique Telephone Co. has recently constructed a long distance line to Garden. The line will be continued to Gladstone and Escanaba.

NORWAY, MICH.—The Menominee Range Telephone Co. has completed its line to Pine Creek.

CLOQUET, MINN.—The Duluth Telephone Co. has been making extensive improvements.

EVELETH, MINN.—The Mesaba Telephone Co. is building a new line into the city.

BEATRICE, NEB.—The Independent Telephone Co. is making plans to build another telephone line southwest of Blue Springs as soon as possible.

FREMONT, NEB.—The Fremont Telephone Co. will extend its line into new territory at once.

GLOUSTER, N. J.—The Peoples Rural Telephone Co. is completing its system of rural lines in this county.

VINELAND, N. J.—The Interstate Telephone Co. has begun the construction of a trunk line from Vineland to Pleasantville.

FARMINGTON, N. Y.—The Wayne-Monroe Telephone Co. will make a number of extensions to its rural line in the near future.

FESSENDEN, N. D.—A new telephone exchange is to be installed here.

SALAMANCA, N. Y.—The Independent Telephone Co., of Salamanca, has completed the construction and equipment of three copper circuits to Buffalo, via Gowanda. Direct service is thus established to all towns in the vicinity now reached by the Inter-Ocean Co.

GRAND FORKS, N. D.—The long distance line of the Tri-State Telephone Co. was recently completed from this city to Minneapolis, Minn.

COLUMBUS, O.—Work on the new telephone circuit from Columbus to Toledo has been completed by the United States Telephone Co. as far as Amline, a point near Marysville. The circuit will be completed as far as Marysville in about ten days. From Columbus to Marysville a new cross arm is being added to the United States company's poles, but north of that point there is a space on the present arms sufficient to accommodate the new Columbus-Toledo circuit. In addition a new circuit is being built from Columbs to Plan City; and Marysville, it is said, will have an additional line into Columbus.

LAKEVIEW, O.—The United Telephone Co. has reached the grand total of 2,600 telephones on their system, and 311 miles of toll lines. Preparations are being made to install a large number of telephones next sping all over the whole system.

MARYSVILLE, O.—The new circuit of the United States Telephone Co. from Columbus to Toledo, will be completed as far as Marysville within ten days. A new circuit will also be built from Columbus to Plain City.

CANONSBURG, PA.—The State Mutual Telephone Co., a branch of the Pittsburg and Allegheny Telephone Co., is arranging to place a pay station in this village and will build a line from McConnells Mills to Canonsburg.

CARMICHAELS, PA.—The Carmichaels Telephone Co. has purchased a new switchboard and will have it installed soon. Business has grown so rapidly of late that this was necessary.

LOCK HAVEN, PA.—It is proposed to construct a telephone system reaching all of the principal farmers in Frankstown, Catherine, Tyrone, Blair and Logan townships, with connections to all the towns in Blair county.

MEYERSDALE, PA.—The Economy Telephone Co. is making a number of extensions and improvements to its system. It has a construction crew at Berlin, where it is putting in an exchange. It is about ready to enter Somerset borough. It will also have a spur line or two from Berlin.

WATSON, PA.—J. J. Beatty, of Watson, is superintending the building of an extension to the Meadville Telephone Company's inlet line. Mr. Beatty is also ooking after other extensions for the company.

BEAUFORT, S. C.—The People's Telephone Co. will extend its lines from Yemassee to Pocotaligo and McPhersonville. The company will also extend its line from Beaufort to different points along Broad river.

PAXVILLE, S. C.—The Sumter telephone line is being extended from here to Summerton.

ELK POINT, S. D.—Mr. W. W. Main is preparing to biuld a twelve-mile telephone line to Spink.

SALT LAKE CITY, UTAH.—The Utah Independent Telephone Co. is pushing its extensions in the direction of Bingham, Provo and Park City. The first mentioned place will be reached in three weeks, and the other two in the spring.

ORWELL, VT.—The Co-operative Telephone Co. is extending its lines to this village, where they will connect wth the Peoples line at Brandon. It is also building to Ticonderoga by way of Mount Independence.

SOUTH ROYALTON, VT.—The Rapid Telephone Co. is building a line from Hartford to White River Junction.

WEST UNION, W. VA.—The Peoples Telephone Co. is now putting in poles and preparing to wire this town and put in a telephone system.

WASAU, WIS.—The Wausau Telephone Co. is building a line to River View Park to give Mr. M. C. Thorn connection.

LARAMIE, WYO.—J. T. Jones has secured a contract to construct another seventeen miles of telephone line near Elk Mountain.

Bituminized Fiber Conduit
For Underground Construction

Combines the **good features** of other conduits. **Eliminates** the **bad features** existing in many kinds. **Has valuable features** not found in any other ducts. :: ::
Made in 7-foot lengths with male and female joints, making construction very rapid and simple, with consequent low cost. :: :: ::
Alignment is perfect and permanent without tedious care and skill required in laying of butt-joint conduits. Users are astonished by the ease and rapidity with which cables can be drawn in, and this without the slightest scratching or injury to the lead covering thereof.
Made in sizes from 1-inch to 10-inch diameter. ::
Bends of any radius and any angle. :: ::

THE AMERICAN TELEPHONE JOURNAL

The Greatest Bargain

Last week we said the best advertising medium for reaching the telephone trade was the most popular telephone paper.

We offered proof in the shape of a voluntary letter of praise from a prominent telephone man that THE AMERICAN TELEPHONE JOURNAL was the most popular paper.

Here is more proof:

"I consider THE AMERICAN TELEPHONE JOURNAL the greatest bargain I ever knew."

FRANK M. WELCH,
Telephone Constructor,
Martinsville, Ind.

Very convincing, is it not? We have a thousand and a half other letters equally as strong.

PAUL LATZKE, President WILLIAM H. McDONOUGH, Editor

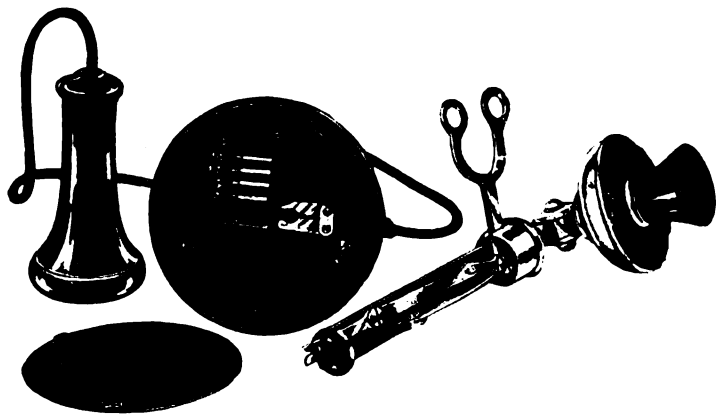
DEAN

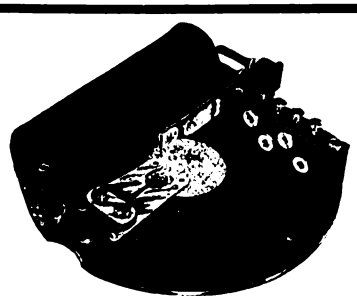
TELEPHONE APPARATUS

MADE with a seamless steel inner framework. Exposed metal parts are finished in heavy nickel plate. Upright encased in a hard rubber tube. No unsightly wear or tarnish.



THE Dean desk stand can be opened as shown above without the use of tools or without disturbing the wiring, thereby fully exposing all working parts. No loose screws or small parts to be lost in this operation.

The hook switch contact springs are mounted edgewise within the base, and are open for inspection by simply removing the base cover.



THIS INTERCHANGEABLE CIRCUIT PLATE, mounted in the base of the Dean desk stand, contains all of the talking apparatus, switch springs and connecting rack, completely wired. These units are arranged for ***local*** or ***common battery,*** the remainder of the stand, excepting the transmitter, being the same for both services.

For a complete description see our little booklet No. 2, which will also tell you why Dean telephones give the best possible service.

MILITARY TELEPHONES

By Dr. Alfred Gradenwitz.

MODERN warfare extends over so great areas that too much stress cannot be laid upon the preparation of facilities whereby a commander may be placed in constant relation with all of the corps which are operating on the field. In the past much attention has been given to the development of telegraphic facilities, in such a manner that telegraph stations could be installed and a line strung from place to place around the battlefield with great celerity. And now the telephone comes to the front demanding recognition for the same purpose.

It would be trite to endeavor to repeat all of the advantages to which telephonic communication could be put as an aid to the military commander. The lightness and portability of the apparatus, the ease with which a line can be strung, and the fact that communication does not require any particular skill, as is necessitated by the Morse code, all go to make this means of communication particularly advantageous for the temporary work of the battlefield. Even in times of peace, telephonic communication between the divisions of a practice corps, or upon the grounds of a military academy, as a means in training, cannot be overestimated.

At first sight it would appear that a cavalry regiment could have very little use for the telephone, as it would naturally have to be operated over a space so great as to preclude the possibility of connection by wire. But even here the telephone has found an acceptable field. Each trooper can carry upon his saddle a light coil of wire, and may often rapidly string the same along the ground by allowing his horse to walk, while the cable unwinds itself; and thus in a reconnoissance a single horseman may convey in this manner to headquarters information which could not be secured in any other manner.

The technical side of the problem of building telephones for army use is a serious one, to which but little attention has been given in the past; and consequently it is not unnatural to find that telephonic apparatus has not been received by the army with particular favor. It is necessary to design special apparatus, as the conditions to which the instruments are exposed are entirely different from those commonly found. For example, in frosty weather the breath of the speaker will congeal and be deposited as a film of ice upon the diaphragm, preventing the receiver from responding. Or the telephone outfit may fall into a ditch, and, becoming thoroughly saturated, will be entirely out of commission, unless built in a manner to be absolutely water proof.

The horse of a cavalryman may become entangled in the wires over the field and rupture same by a single kick unless so constructed as to withstand an accident of this description. In a general way, all of the apparatus should be built in the most solid, substantial and durable manner, with particular care to the avoidance of all screws, binding posts and other parts which are likely to be loosened under severe usage. Each portable outfit should be so designed as to be practically ready for instant service, avoiding entirely the consumption of valuable time in unpacking and arranging the instruments in such a manner as to be ready to talk.

It would appear on first thought that simplification might be secured by using a magneto instrument both as a transmitter and receiver; but, unfortunately, it has never been practical to build

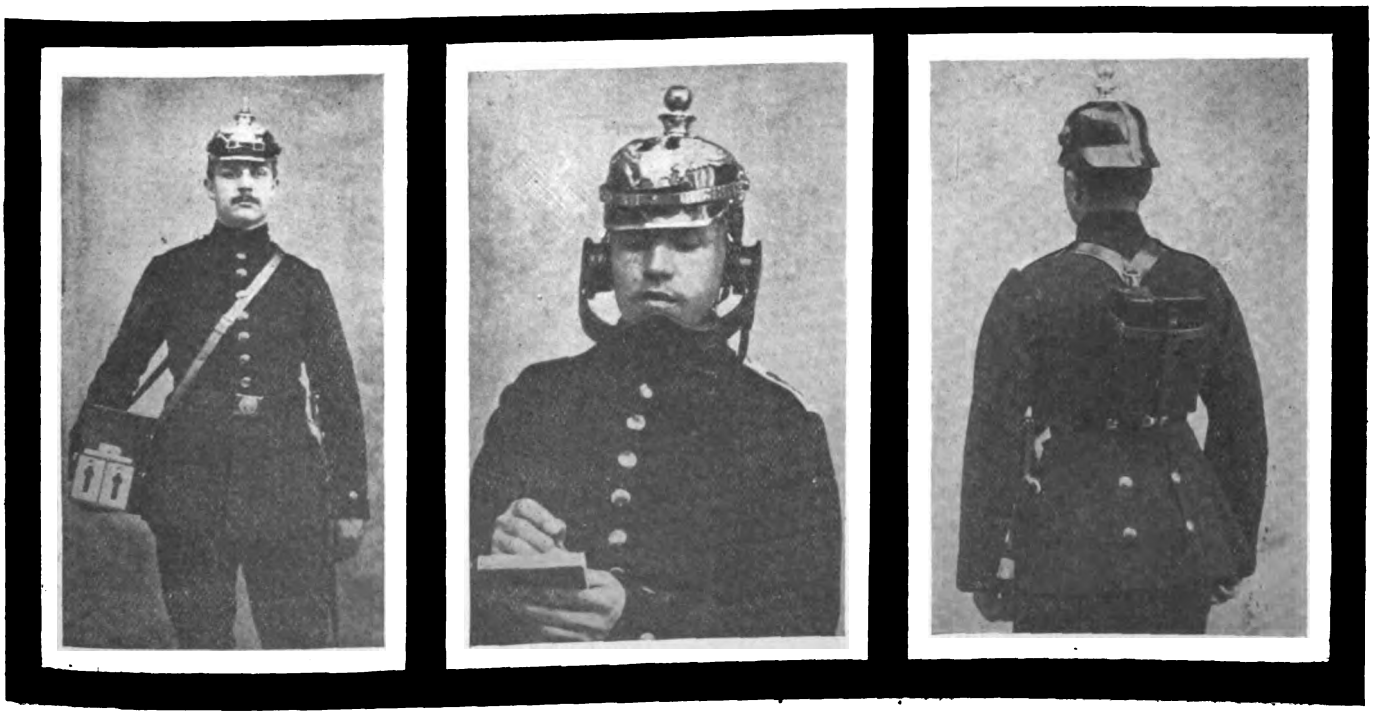

Fig. 1. German soldier equipped with scout set.

Fig. 2. Combined Transmitter and Receiver with Head Piece to Allow Free Use of Hands.

Fig. 3. Portable Carrying Case as Worn on the Back Similarly to a Knapsack.

Digitized by Google

one which would talk with sufficient loudness to be valuable upon a battlefield; and, therefore, the regular outfit of the carbon microphone and a magneto receiver must be provided in order to be serviceable. The receiver should be particularly compact, and at the same time provided with very powerful magnets and windings proportioned to the current sent by the transmitter. It is well to supply every set with a pair of receivers arranged upon a proper head brace, so they may be secured to both ears of the operator in such a manner as to leave his hands entirely free for other manipulations. The microphone must be an exceedingly

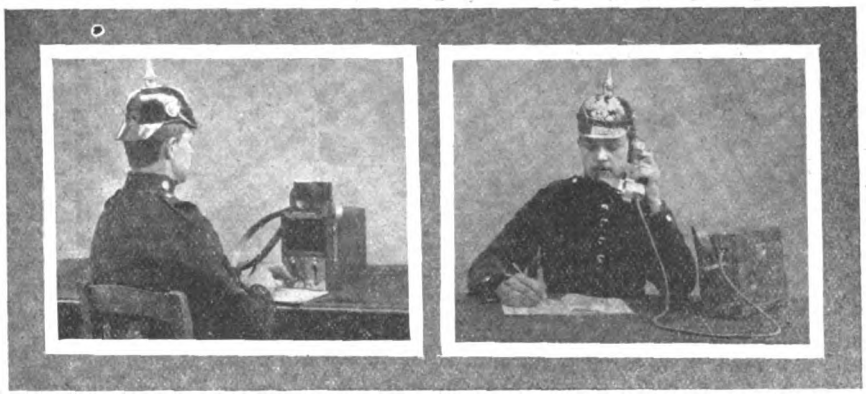

Fig. 4. Telephone Scout Set of German Army in Operation.

Fig. 5. Portable Set Using Hand Microtelephone.

powerful one, preferably provided with a carbon diaphragm, for it has been found that a carbon diaphragm can be made sufficiently substantial so that it will not be injured in transportation. From many standpoints the carbon diaphragm is less liable to accident from other causes than the ordinary metallic one, and superior in its ability to give free, clear, distinct and loud transmissions. To produce a loud-speaking transmitter, it is necessary to so arrange the granular carbon that it shall not burn or oxidize under the heavy currents delivered by the battery; and it is also desirable to so design the microphonic parts that they may be readily replaced in case of accident, and to provide each cavalryman with one or two duplicate carbon capsules, which may in a few seconds be inserted in case of accident.

The calling device is an important feature. The ordinary call bell has not been found so successful as the buzzer, and for many reasons; notably the fact that the call bell produces too loud and piercing a tone, and frequently might notify the enemy of the presence of a scout. Again, the buzzer can be made to operate inductively from a telephone line and thereby can transmit Morse signals, or any other form of code which may be adopted, insuring the secrecy of the messages sent. For this purpose a differential buzzer designed by Mix & Genest is so arranged as to do away with all adjusting springs, employing two magnets, one of which operates against the other in a differential fashion. This avoids complication and the liability to disarrangement which is inherent in the spring, and provides an instrument which may be operated with any intensity of current that may be desired. In some cases the telephone stations may be so arranged as to use the Rysselberghe system, thus rendering it feasible to talk and telegraph simultaneously over the same set of conductors. The Germans have recently made considerable advance in the designing of military telephone apparatus, which is herewith illustrated.

Figs. 1, 4 and 7 show the scout set, which is of simple construction, the entire apparatus being contained in a case carried over the shoulder by a leather strap. When desired for use, it is simply necessary to unstrap the box and open the cover, disclosing the microphone. In this instrument the receiver can talk sufficiently loud so that those with fairly acute hearing can understand conversation without the necessity of attaching the receiver to the ear. Another form of apparatus is illustrated in Figs. 6 and 8, which is simply a modification of the familiar combination set so frequently seen in Europe. This may be as light and small and compact as possible, so that it may be placed in the pocket without requiring the use of the carrying case.

Fig. 2 suggests a system in which the receivers and microphone can be attached to a single head band, and thus enables the operator to clamp the three instruments in the best respective positions upon the head, both for receiving and for talking. Fig. 5 is a type of portable apparatus contained in the carrying case, which includes all of the accessories which are necessary, such as battery, call bell, band, receiver and transmitter. The box is made of aluminum, so as to be strong and at the same time light, and can be readily carried in a leather pouch or in the saddle bag. The batteries must necessarily be proportioned to the service. They are dry cells, having small internal resistance, and possessing a charge capable of developing strong currents for a short period of time. Fig. 3 shows the portable carrying case shown in Fig. 5 attached to the back of an officer in such a way as to be easily carried, and at the same time attract but little attention. The field conductors form an important part of the outfit, for the value of the telephone in the field depends very much upon the quickness with which a conductor may be strung and the message delivered. The best conductor for the purpose seems to be a pair of fine copper wires, carefully insulated, and then overstrung with a couple of fine steel wires of the strongest description. By this means a cable of great flexibility and at the same time of great strength, together with the necessary insulation, can be secured.

The obvious advantages possessed by the telephone where it has been designed for military work has not been overlooked by any of the progressive powers. In Germany perhaps, the mechanical design has been furthest developed, but other countries are not far behind. In England its use has become general, primarily from the results obtained in the South African war. Russia and Japan each place a great deal of reliance upon telephonic communications, there being several instances on record where the telephone was a prime factor in attack and defense. In the United States telephone scouts form a part of the forces of many of the regiments of the National Guard, either as an independent corps or else in conjunction with the electrical department of engineering battalions, and in the regular army the telephone is rapidly supplanting other means of communication.

THE CONSTRUCTION OF RECEIVER HOLDERS.

By Harold A. McMann.

PROBABLY no inconvenience incidental to the use of the telephone is more greatly experienced than that of holding the receiver to one's ear. The necessity of doing this naturally precludes the use of both hands for writing, etc. Devices are constantly being brought forth to overcome this difficulty, but to one of a mechanical or ingenious turn of mind, the construction of a home-made holder may prove of interest; to one at all familiar with the use of ordinary tools the problem will present few difficulties.

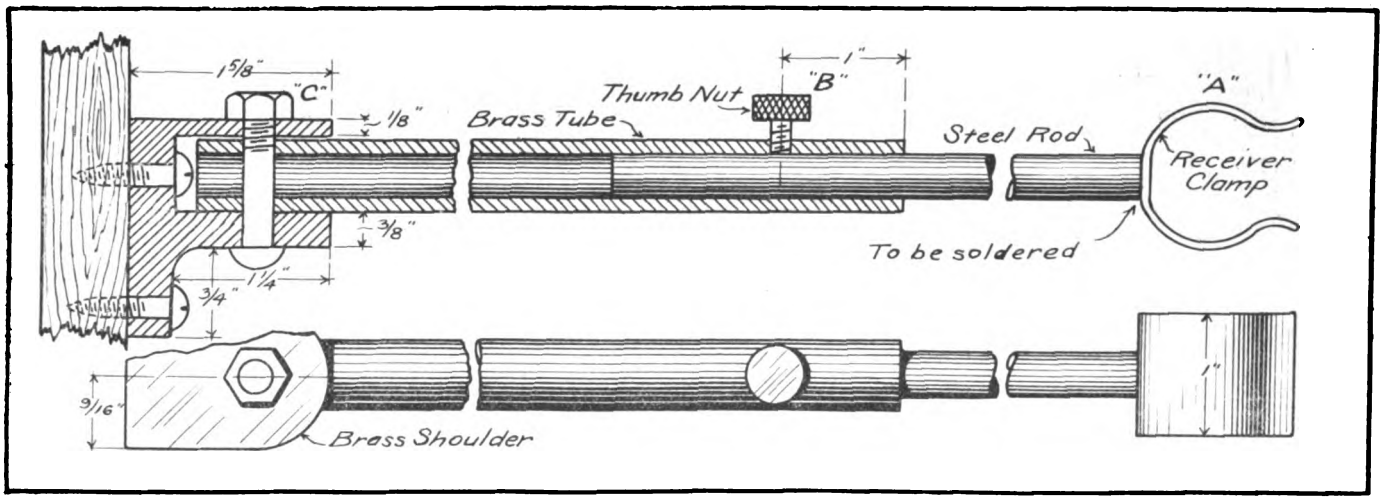

Fig. 1.

In Fig. 1 is illustrated one type of holder that may be easily made. The first thing to get is a piece of steel rod 3/8" diameter and about 8" long. Next obtain a piece of smooth, straight brass tubing about 12" long; the inside diameter of this tube should be a trifle over 3/8" to enable the rod to slide in and out without causing it to jam. At one end of the tube a hole 3/16" in diameter should be drilled about 1" from the end of the tube and tapped with a 1/32" thread; a small thumb nut should be fitted to the hole. At the other end of the tube, about 1/2" from the end, a 1/4" hole should be drilled. A clamp to hold the receiver should now be made of a springy piece of brass about 3/32" thick and 1" wide, and bent to conform generally to the shape of the receiver; this is shown at "A" in Fig. 1. It should be bent so that when the receiver is put in place it will be held firmly; it is also a good plan to glue a piece of felt on the inner side of the clamp to avoid marring or scratching the receiver. The clamp should now be soldered to one end of the steel rod, as shown in the drawing.

The next consideration is a shoulder or brace to hold the brass tube; this should be, if possible, cast of brass according to dimension of the drawing. If the means for casting are unavailable it may be filed out of a piece of soft brass. Two holes should be drilled, 3/16" in diameter, through the back, and two holes through the two lugs; these latter two should be large enough to accommodate a 1/4" bolt.

The brass tube may now be fitted to this shoulder and held in position by a 1/4" bolt and nut. The steel rod should be slid in the tube and the thumb nut tightened up; if the rod slides in and out too stiffly a little oil or graphite may be applied, which will remedy the evil.

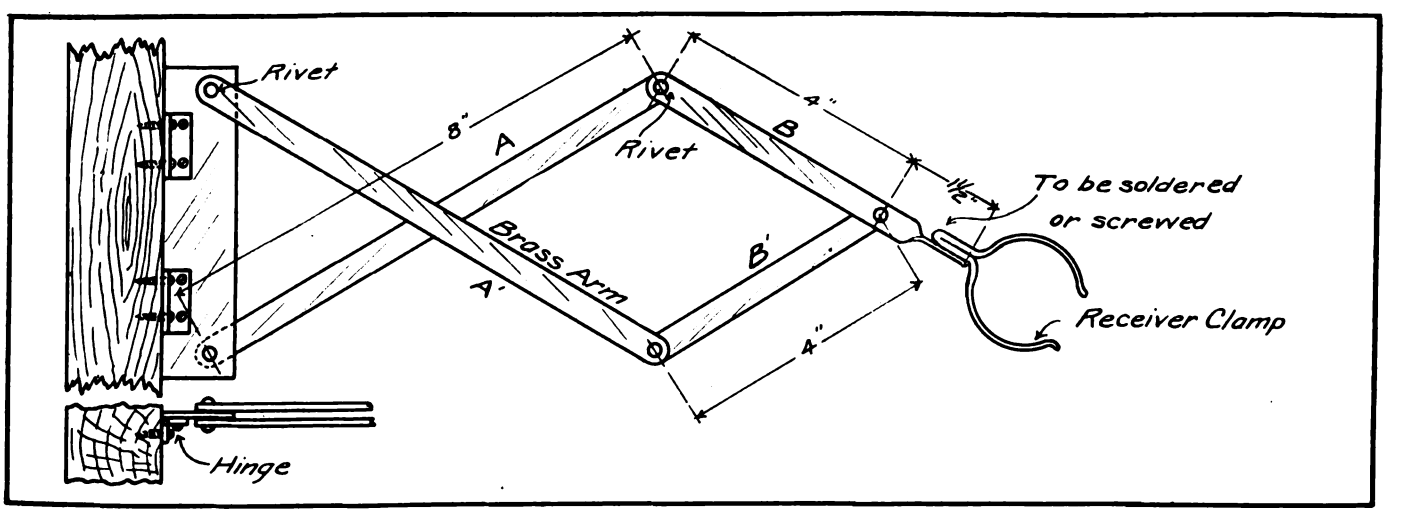

Fig. 2.

The contrivance is now ready for use; it should be screwed either to the backboard of the telephone or the wall. The receiver is placed in the clamp and the steel rod slid in or out until the desired adjustment is obtained; the adjustment may be made permanent by tightening the nut "B." The nut on the shoulder at "C" should be loose enough to allow the tube and rod to be swung clear of the telephone when not in use, and yet not so loose that it will swing out of position when the ear is applied to it.

Digitized by Google

The second type of receiver holder is illustrated in Fig. 2. It consists essentially of a series of hinged arms working on the lattice principle; these should be ½" wide and ⅛" thick. The arms A and A^1 are 8" between the centers of the holes at each end, which are 3/16" in diameter. The arms B and B^1 are 4" between centers, with 3/16" holes at the ends; the length of the arm B should be about 1½" longer beyond the hole on one end than on the other, and should be twisted 90°, as shown in the drawing; this extension is to provide room for the receiver clamp, which should be soldered or screwed on. The shape of this clamp differs slightly from the one previously described, but is made of the same material.

All of the arms should be neatly rounded off on the ends and put together either with rivets or small bolts and nuts; the rivets are to be recommended, as there is no possibility of their working loose. A block to hold the now completed lattice should be made of a piece of brass ½" thick and about 5" long and 1" wide; two small, stout hinges are to be fastened on one side, as shown in the drawing, to enable the device to be swung out of the way when not in use. Either of these receiver holders may be greatly improved in appearance if nickel plated, which can be done at a small extra expense.

The third type is constructed on very original lines, as shown in Fig. 3. It consists principally of the flexible part of a portable electric-light holder, which may have been relegated to the proverbial scrap heap. The base and standard should be cut off with a hack saw at "A," leaving about 2" of the standard; the lamp socket may easily be removed by taking out the screws that hold it together.

A base should be turned out of brass or hard wood; if a lathe is unavailable it may be made square with equally good results. A hole should be drilled and tapped in the center, and the end of the standard screwed in place; a thread should be cut on the end for this purpose. A clamp for holding the receiver may be made according to the drawing, of the same material as the previous ones; a small hole is to be drilled in the center. The end of flexible tube should be plugged up with hard wood; then through the hole in the clamp insert a screw, and fix the clamp to the end of the tube.

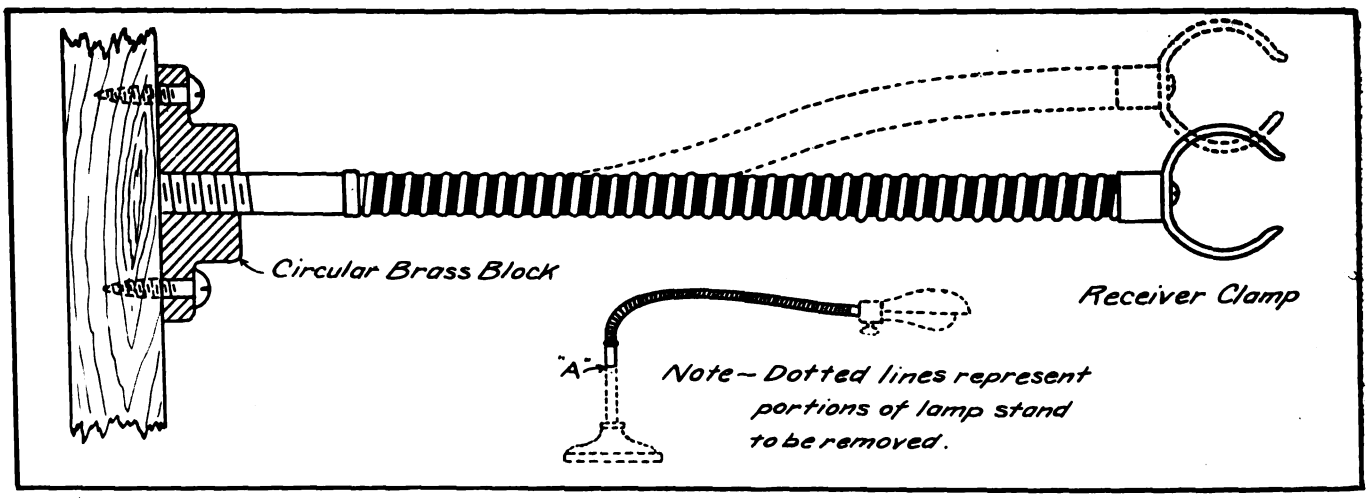

Fig. 3.

This holder is intended to be screwed to the backboard of the telephone or wall, similar to the ones previously described; a few holes may be drilled in the brass or wood block for this purpose. This holder is probably the simplest one to rig up, and gives better satisfaction. It is capable of being put in almost every conceivable position, and is practically rigid when set in position, and will not swing out of the way.

If, with any of these receiver holders the receiver is to be fixed in the clamp permanently, it will, of course, be necessary to provide a weight sufficiently heavy to keep the receiver hook down when not in use.

TELEPHONE EXCHANGE ENGINEERING

ARTICLE XXI.—CONDENSERS (Continued).

By Ray H. Manson, Albion D. T. Libby and Charles A. Simpson.

Voltmeter Method: A high resistance voltmeter is often used for measuring the insulation resistance of condensers.

A voltmeter is connected in series with a battery and the condenser under test, as shown in Fig. 96. The reading obtained is compared with that of the same circuit with the condenser cut out. This expressed in the terms of a simplified formula, will be $I = r\left(\frac{v}{x} - 1\right)$, where I is the insulation resistance in ohms, r the resistance of the voltmeter, v the voltage with the condenser cut out of circuit, and x the voltage with the condenser in circuit.

If a 150 scale voltmeter is used, having a resistance $r = 17{,}500$ ohms (voltmeter resistance is always specified by the manufacturer) and a battery which shows a voltage $v = 140$ volts, then the reading with a certain condenser in series is found to be ½ a volt. Substituting these values in the formula $I = 17{,}500\left(\frac{140}{0.5} - 1\right) = 4{,}882{,}500$ ohms or 4.88 megohms.

It can be seen from these figures that higher insulation resistances would give a smaller value to x which would be difficult to estimate with any degree of accuracy on the regular voltmeter scale. A more sensitive voltmeter and battery of higher voltage would give a larger reading and more accuracy. With a constant battery voltage it would be possible to calibrate such an instrument so as to read directly in megohms, thus making a very convenient commercial method of measuring insulation resistances of condensers.

Galvanometer Method: This means of measuring insulation resistance is essentially the same as the previously described voltmeter method, but the use of a properly designed galvanome-

Digitized by Google

ter will allow of very accurate results. Fig. 97 shows the circuit connections. The battery *B*, galvanometer *G*, and condenser under test *K* are connected in series and the circuit closed by pressing the key *A*. The deflection of the galvanometer is that due to the current passing through the insulation or dielectric of the condenser, and is inversely proportional to the resistance. Having obtained the deflection through the condenser, the "constant" of the galvanometer is divided by it and the result is the insulation resistance of the condenser in megohms.

The "constant" of the galvanometer is that deflection which would be obtained were the galvanometer in series with one megohm resistance and the testing battery.

In obtaining this constant the connections are same as before, but a standard resistance is substituted for the condenser, as shown in Fig. 98. The standard resistance taken is for convenience, usually 1/10 of a megohm (100,000 ohms) as larger units would be too bulky and expensive for regular use. The deflection obtained through the standard resistance would in this case be multiplied by 10 to get the constant in terms of megohms. This constant, once correctly obtained, can be used through a long range of tests and needs only to be taken at intervals to check the testing circuit and make sure that the conditions have not changed.

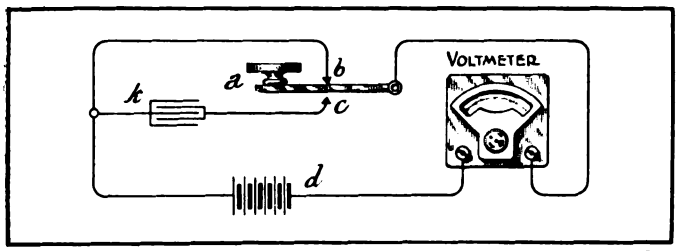

Fig. 96. Voltmeter Method of Measuring Insulation Resistance of Condensers.

An example of the above methods is as follows: In taking the constant of the galvanometer a reading of 90 scale divisions is obtained with a 1/10 megohm standard in series with the testing battery and galvanometer. This would give a "constant" of $90 \times 1/10 = 9$. Now, if the deflection with the galvanometer, battery and condenser connected in series, as shown in Fig. 98, is 4 scale divisions, the insulation resistance of the condenser would be $9/4 = 2\frac{1}{4}$ megohms.

In making galvanometer tests it is often necessary to shunt part of the current from the instrument in order to keep the deflection on the scale. A common form of shunt which can be obtained for any make of testing galvanometer has four steps calibrated so as to allow either 1/10, 1/100, 1/1,000 or 1/10,000 of the current to pass through the galvanometer, and the remainder through the shunt. If the 1/100 shunt was used to bring the deflection on the scale and leave it sufficiently large to give an accurate reading, it would be necessary to multiply the reading by 100 to obtain the true value of the deflection.

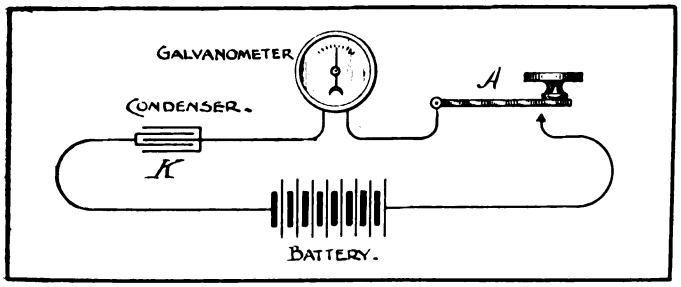

Fig. 97. Galvanometer Method of Measuring Insulation Resistance of Condensers.

If a 1/100 shunt had been used in obtaining the above constant and the same deflection of 90 resulted, then its value would have been $90 \times 1/10 \times 100 = 900$. Now, if the deflection, when testing the insulation resistance of a condenser, was 40 scale divisions, the actual resistance would be $900/40 = 22.5$ megohms.

In making insulation tests by the galvanometer method it is best to put a 1/10 megohm resistance in series with it to prevent the battery current from doing damage should a condenser under test be crossed. Fig. 99 shows this modified testing circuit as well as a four-step shunt placed around the galvanometer for varying its sensitiveness. A short circuiting key *A* is used to shunt out the galvanometer when not in use, instead of opening its circuit. This is the usual wiring for a galvanometer test circuit, the "constant" of the galvanometer and the insulation resistance tests being performed as previously described. The numerical value of the 1/10 megohm resistance can be neglected in commercial condenser tests, but where great accuracy is desired its value should be subtracted from the result to give the true insulation resistance.

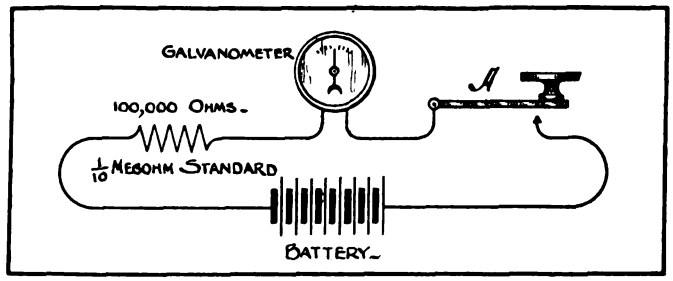

Fig. 98. Method of Obtaining Galvanometer Constant for Resistance Measurements.

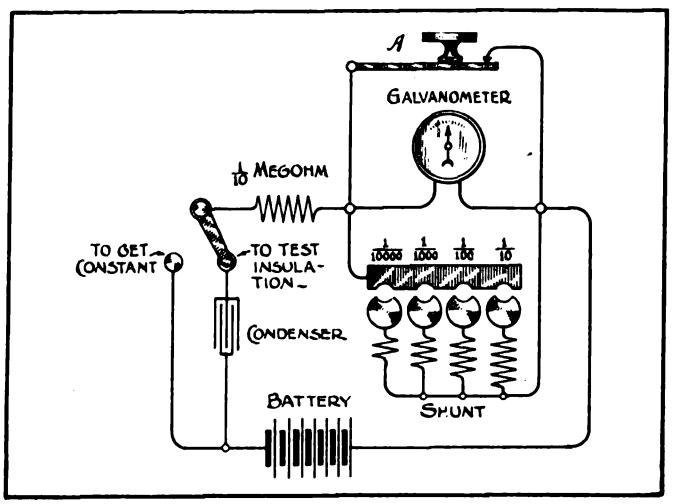

Fig. 99. Complete Galvanometer Circuit Arranged for Measuring Insulation Resistance of Condensers.

MEETING OF TRI-STATE INDEPENDENT TELEPHONE ASSOCIATION.

THE Tri-State Independent Telephone Association held a meeting recently at Westville, I. T. The main points discussed were ways and means for mutual benefit and protection and also for the betterment of local and long-distance service.

H. E. Scovern, manager of the Home Telephone Company, of Joplin, Mo., delivered an address upon "The Value of Toll Lines." A proposition to build a new circuit from Little Rock, Ark., was discussed and it is thought will be put through at an early date. The proposed line will run from Little Rock to Fort Smith to Tahlequah, I. T., through to Fayetteville to Monett, Neosho and Joplin.

Among the telephone men present at meeting were:

H. E. Scovern, manager Home Telephone Company, Joplin, Mo.; H. C. Slaughter and Mr. Berry, North Arkansas Telephone Company, Fayetteville, Ark.; J. I. Potter and D. M. Bostwick, Potter Telephone Company, Gravette, Ark.; W. T. Stehl, Siloam Springs, Ark., Telephone Company; M. M. Collier, Prairie Grove Telephone Company; J. L. Lauderman, Pann Telephone Company, Fort Smith Ark.; A. R. Carroll, Cane Hill Telephone Company; W. D. Wasson, Wasson Telephone Company, Gentry, Ark.; K. G. Comfort and T. A. Cales, Westville, I. T., Telephone Company.

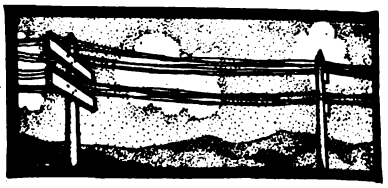
QUERIES

Questions on any subject relating to telephony will be answered on this page.



TREE SUSPENSION.—(481.)

We can save a number of poles in a run in to a subscriber's place from the main line if we suspend the wires to the trees. Will you show us a way to do this? P. F.

A method which is often employed to suspend lines to trees is shown in Fig. 481, and requires but little explanation. In the figure twisted wire is shown running through an insulator suspended from a limb of a tree. The reason for using the insulator is this: If the wire is fastened directly to the tree and it sways in the wind the probability is the wire will break, whereas when the insulator

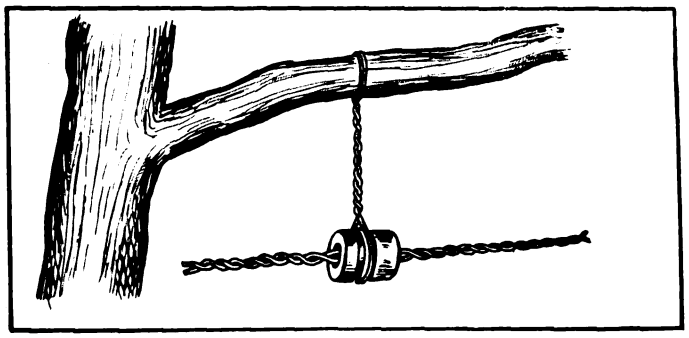


Fig. 481.

is used a flexible support is formed which allows the wire to be held in place irrespective of the movement of the tree.

MAGNETO BOARD CORD CIRCUIT.—(482.)

Will you kindly draw me a diagram of a magneto switchboard? I only want the cord circuit. A. S.

Almost every type of switchboard varies to some extent, and this is true of the cord circuit. In Fig. 482 is illustrated one which will give a good general idea of the requirements. The circuit illustrated is for one-way ringing only.

TWO WAY LISTENING KEY CIRCUIT.—(483.)

Will you please describe what is meant by a two way listening key circuit giving diagram? G. N.

A two-way listening key circuit is one in which the operator in listening in on one cord cuts out the remaining half. Such a circuit is illustrated in Fig. 483. It will be noticed that the operator's set is bridged on to the outside contacts of the key, the cord circuits to the middle contacts and the clearing out drop to the inner contacts. The normal position of the key is with middle contacts closed to the ring off drop. Thus either side of the line is able to call the operator. If the operator wishes to listen in

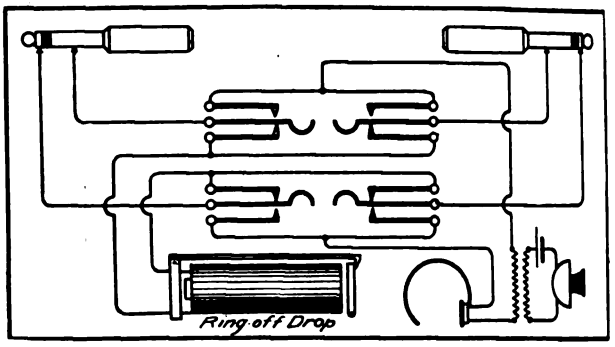

Fig. 483.

she moves the key, opening the circuit between the parties talking and closing one side of the line through to her listening set.

GENERAL QUERIES.—(484.)

We have telephone sets of a small box type placed in hotels with a switchboard. These sets have no induction coil at telephone and are intended to talk long-distance as well as local. How is it accomplished? Where can I find a book that will give information about circuits, etc., of switchboards used by this company? I have a line on my district that has one subscriber, a doctor, which uses X-rays, static, and other apparatus of that style to a great extent; others on the line complain frequently of being noisy. The subscribers are under the impression a swing-gound is the trouble, but if that was the case it would show up in office on signals, etc. I have not been able to catch noise yet, so cannot express my opinion. Could the apparatus mentioned cause trouble? J. W. N.

In reply to your queries, we beg to advise you that we believe you are in error in considering that substation instruments which are not supplied with induction coil are intended to be used on long-distance circuits. Such instruments are not intended for this purpose, the induction coils being intentionally omitted so they cannot be used successfully on long lines.

In reply to your second query respecting switchboard circuits, since you fail to give us the name of the switchboards used by this company, the company to which you refer, it is impracticable for us to reply.

As to the third, unless the subscriber attaches his induction coil or static electrical machine directly to the telephone lines, there would be no probability of his apparatus causing any noise. Your difficulty is probably due either to a grounded line or to a parallel electrical light or power wire.

The Telephone in the Courts

Conducted by A. H. McMillan.

Readers are invited to submit questions on any point of Telephone Law. They will be answered and explained on this page.

FRANCHISE TAXES.

On March 4th, 1904, a franchise was issued to the Wm. N. Knotts Telephone Co., of this city, the franchise running for a period of twenty years. One paragraph in the franchise reads as follows: "In consideration for the privileges granted in this franchise the said telephone company agrees to pay into the treasury of the incorporated town of Medaryville, 10 per cent. of the earnings of each telephone maintained." For the first two years Mr. Knotts paid $28 per year. On May 1st, 1903, Mr. Knotts took a partner, and on November 1st he sold out, leaving the plant in the hands of a new company. When the new company went to pay the franchise taxes for 1903 the treasurer demanded the 10 per cent. on the gross earnings. We went before the Board asking a reduction. The Board cut the rate to 5 per cent. from March 1st, 1904, but instructed the treasurer to collect 10 per cent. of the gross earnings up to that time. Can the Board collect? We contend it is too much and no telephone company can exist under such rules or taxation. W. N. K.

THE paragraph in the franchise is perfectly valid, and the town can collect the franchise taxes there provided for. It would be a question of fact whether the per cent. should be taken upon the gross earnings or the net earnings. It would seem the town, having interpreted it for two years to mean net earnings, would not then be allowed to change this interpretation and collect the taxes upon the gross earnings.

FRANCHISE FROM STATE.

THE Laws of New York (Laws 1890, Pg. 1152, C. 566, Sec. 102) gave to a telephone company the right to erect and maintain the necessary fixtures for its wires over any of the public roads and streets within the State. A law passed in 1897 authorized the trustees of villages to regulate the erection of telephone poles and the stringing of wires over the State. The trustees of a village adopted a resolution authorizing a certain person to erect poles and fixtures and to string wires for the telephone system under the direction of the trustees and in their resolution declared that if the work was not completed within the specified time the consent should cease. The work was not completed within the specified time and it was contended that the consent of the village had ceased and the telephone company had no right to demand a right of way in the State. The Supreme Court of New York held that the franchise to use the streets comes from the State and the power to regulate the erection of the poles and wires in the streets of the village rests with the trustees, making it immaterial whether the consent granted by the village had expired or not. The telephone company could therefore demand a right of way although its line was not completed within the time prescribed in the resolution of the village trustees.

The Court held further that the telephone company should be permitted to acquire in condemnation proceedings an easement for its poles and wires in the street.

New Union Telephone Co. *vs.* Marsh 89 N. Y. 79, 96 App. Div. 122.

EXCAVATION IN HIGHWAY.

A SUIT was brought against a Telephone Company for damages for failure to safeguard with due care an excavation made by it in a public highway. The trial court was requested by the defendant to charge the jury: "That the duty of the defendant was to exercise reasonable care in protecting by fence or guard its manhole, and that it was not, in the exercise of this duty, necessary that it should provide the best appliances or guards, but only such appliances and guards as were well known and in general use." The Supreme Court held that this request correctly stated the law and should have been charged as applicable to the case in hand. Each of the propositions contained in the request was pertinent to the issue that had been tried, and the second of them was especially pertinent. The rule of law stated was applicable to the conduct of the cause within the issue that was submitted to the jury, and hence when the defendant requested the court to instruct the jury upon this point, it was the defendant's right to have the law correctly stated. Van Vechten vs. N. Y. & N. J. Telephone & Telegraph Company. 58 A. 1096.

A QUESTION FOR THE JURY.

WHERE the person using a highway was injured by coming in contact with the telephone wire, which had fallen on the wire of an electric railway, which used the same supports for its wires as did the telephone company, and such detached wire became heavily charged with electricity, in an action for the injuries it was a question for the jury whether the telephone company was negligent in failing to properly guard its wire and it was proper to deny a motion to take the case from the jury and render a judgment for the telephone company.

Burton Telephone Co. *vs.* Gordon, 25 Ohio Cir. Ct. R. 641.

RECKLESS HOUSE MOVING.

AN illustration of the dangers and damage that may arise when house-movers interfere without authority with wires belonging to telephone and other electrical companies is found in the recent case of Nagle vs. Hake, decided by the Supreme Court of Wisconsin.

Hake, a house-mover in Milwaukee, was moving a building along Walker street, and to gain passage for it took down an unused telephone wire belonging to Julius Andrae & Sons' Co. This wire, as it crossed National avenue at the intersection of Walker street, hung a few inches above an electric-light wire heavily charged with electricity and belonging to an electrical railway company and protected only with a coating of weather insulation. The plaintiff, a boy about eight years old, lived with his parents in a house near the intersection of the above-mentioned streets. When the house-mover reached the wire with his building he cut it, and, rolling up the end for some distance in a coil on his arm, he hung the coil on a nail in the side of the house where the boy lived. The boy accidentally touched the coil and was severely burned. It was found the wire had sagged where it crossed the street until it rested on the electric-light wire and that the insulation of the latter wire had worn off. Andrae & Sons were made joint defendants, but the suit was discontinued as to them upon their paying the father of the plaintiff $500 and receiving a release for the damages claimed by the father against the company.

From a judgment in favor of the plaintiff the defendant appealed. The Supreme Court held that the release of the father and the discontinuance of suit against Andrae & Sons did not release the defendant. It also held that plaintiff had made out a case and was entitled to recover. Numerous questions of minor interest as to testimony and instructions are discussed.

Nagle vs. Hake (Wis.) 101 N. W. 409.

RESPECTING CONTRACTS WITH BELL COMPANIES.

THE value of Independent organization is having a fine illustration at Middletown, New York. Inspired by its success in seducing the Glen Telephone Company, operating at Johnstown and Gloversville, New York, into a so-called operating contract, the Hudson River (Bell) Telephone Company laid out a scheme for capturing the Orange County Telephone Company at Middletown on similar terms. Immediately this fact leaked out, a hurry call was issued for a meeting of the Independent Telephone Association of Orange and Sussex Counties. This brought to the support of the loyal men in the Middletown company, the support of every Independent telephone operator in the territory, and the weak-kneed stockholders were bombarded with facts and arguments that proved most convincing. Among other exhibits was a letter written by D. A. Reynolds, vice-president and general manager of the State Line Telephone Company, that is operating most successfully in New York State.

This letter, addressed to W. C. Ramsdell, secretary of the Orange County Company, who is and was strenuously opposed to the designs of the Bell Company, makes such a strange presentation, that the editor deems it good policy to reproduce it in full in this column. After a preliminary introduction, Mr. Reynolds says:

> There is one feature in the proposition you have received from the old-time monopoly that would seem to require an explanation, to say the least. For years you have been able to successfully manage your own affairs, and have built up a business of which you may well feel proud. All this time you have been without long-distance connection, but notwithstanding this handicap, you have shown your ability to rival the monopoly and do for your city what they never would do—give good service at reasonable rates. You now have the respect of your people who look at you as their deliverer, and who will doubtless continue their support in ever increasing proportion. You have forced the monopoly to their knees and now that you nave them at your mercy, why surrender to them?
>
> If they had loved you in the past as they love you now, why did they not offer terms before? Is it because they see the handwriting on the wall? No one knows better than they, how near you are to metropolitan connection, with long-distance lines connecting you with 7,000 other Independent telephone companies who have remained Independent in spite of the most alluring offers and magnanimous promises, made only to be broken. They see the same conditions confronting them here in the East, as they had to meet in the West, where the Independents number as high as five to their one, and knowing that the time is short when they must leave the field to the Independents, they are grasping at the last chance to drag you down with them. They cannot hope to make anything direct in Middletown, by the terms they have offered you, but their indirect benefit is far-reaching. If they can tie your hands and take you out of the Independent column, even without momentary benefit, they have added your number of subscribers to their list, strengthened themselves in other localities where they are being pressed as badly as you have been pressing them, and made it impossible for the other Independents to communicate with Middletown until another franchise is granted and another system established. You can safely calculate that any contract they will offer will prove fatal to your further growth, as they never embrace except to ruin.
>
> It is not wisdom for your stockholders to conclude that by walking into the parlor of the monopolistic spider, they will avoid competition. On the contrary, they will do the very opposite. You now have competition whipped to a standstill, and it will only require independence for a short time in order to have the field entirely to yourself, with possibly a single Bell pay-station on their long-distance lines. On the contrary, if you accept their terms and lose your identity, Independent competition will spring up and you will have to compete against local influence and a much wider field, and it would be very strange if some of your own stockholders did not leave your organization and join a ***real genuine Independent*** company.
>
> An illustration of this kind may be cited at Detroit, Michigan, where the Michigan Bell Company offered practically the same terms they have offered you. The Citizens' Company refused it, but William and John Holmes, two of their directors, entered into an intrigue with the monopoly, got hold of a majority of the stock and sold out the plant at a profit of nearly 200 per cent. Immediately another franchise was granted by the city and Detroit is now building a thoroughly modern system, with men back of the enterprise whose honor is above price. The Holmeses, it is needless to say, are out of the telephone business and nearly out of all other business, as they are regarded as men without honor and to be ostracized in all legitimate transactions.
>
> There are a number of such instances in the West, where the monopoly has been driven to the wall, and I cannot call to mind a single city, where the Independent has succumbed to the wiles of the monopoly, where an Independent company did not spring up in its place and drive the unholy alliance out of existence.
>
> To-day, Michigan has 86 Independent telephone companies operating 90,000 telephones, where the Bell had 13,432 before competition. The old company has been guilty of every crime known to the business world for eight years of competition, and finally succumbed to the inevitable, and was closed out the first of the present year by the receiver, with a loss to its stock and bondholders of over ten million dollars. Ohio has twice as many Independent telephones as are operated by the Bell in that State, Indiana two and one-half times as many, Illinois three times as many, Iowa five times as many, while not a single Bell company in twenty-six Western States and Territories has paid a dividend in the past three years. Over 100,000 Independent telephones have been installed in the State of New York in the last two years, and they are increasing in geometrical progression. The Bell Company cannot meet this growth and they are in worse shape in other parts of the State than you have made them in Middletown. They cannot longer sell their securities to meet competition by installing free telephones, for they are now capitalized for from $300 to $900 a telephone, and free telephones do not pay dividends.
>
> They are like an old, decrepit man worn out by excesses and now seeking new blood to keep them alive. They have, in many parts of the country, ceased to be regarded as legitimate, and the manipulations of the Erie Company is only an example of their tactics. How any self-respecting man, as a director of a legitimate business enterprise, can have anything to do with them after knowing that history, is beyond my understanding, and if he does not know the history, he should inform himself before bringing reproach upon himself and his company. It is not safe to play with fire, even if you think you are getting the long end of the poker. Remember the opposition has everything to gain and nothing to lose. You have won your battle, why surrender your honors? You know from

THE BELL AND THE MIDDLETOWN COMPANY.

MR. VERMILYA'S SCATHING OPINION.

I have examined with considerable care the proposed contract to be entered into between the Orange County Telephone Company and the Hudson River Telephone Company, and, after a full discussion with you in reference to the conditions under which your company operates, I am constrained to say that the contract is pregnant with litigation and it assuredly limits the development of any telephone business by your company.

In the first instance, you are limited to the territory included in the limits of the city of Middletown, and are practically cut out of territory now controlled and operated by you. You are also practically cut out of any arrangements that may exist between you and the other companies now operating in Orange County.

The contract is indefinite as to the system that you shall maintain and equip under paragraph fourth, and more particularly in reference to any further equipment that the River Company may demand of you. I am not referred to any rights, privileges and facilities which the River Company has by contract and otherwise with any connecting companies, and I should advise a very careful examination of these contracts in order that it may be determined just what rights the River Company has.

The last clause in paragraph five is very indefinite as to the number of toll lines that the River Company shall maintain. It would seem that the contract should be changed and a definite number of toll lines installed in proportion to the number of instruments in use by your company.

Paragraph six absolutely prohibits your operation with the other Independent telephone companies in Orange County, which is herein above stated.

The agreement as to the delivery of sets and the installation of the same by you is impracticable, for the reason that the deliveries are contracted to be made by the River Company within the same time that you are under contract to install them, and if the River Company should delay the delivery until the latter days of their term, it would be an impossibility, as I am advised, for you to install within the time agreed upon.

As a business proposition, the installation of Bell sets would seem to me to be bad. I am advised that the receivers and transmitters are purchased at about $3, and it is true that you are allowed that sum for those at present you have. On the other hand, it will be necessary to take them all out and install Bell sets. I am not advised definitely as to the life of those instruments, but at $1.20 per year they will very soon come out to far more than $3, and even then you will not own the instruments. If, for instance, the life of the instrument is ten years, for each new instrument installed the cost will be $12, as against $3 now, and for all replaced the cost will be $8.40, as against $3, and your assets will necessarily be diminished by the number of telephones you now have multiplied by their cost, with nothing to counterbalance this loss except a continuous charge.

Further, as a business proposition, it is for you to determine whether or not the increased toll service, by virtue of your connection with this company, will sufficiently counterbalance the charges that you will have to pay, not only in installing further switchboards, lines, etc., but also in paying the rental upon the so-called sets to make it profitable. In other words, if your tolls amount to 4,000 messages per month incoming and outgoing, which would give you $120, under the agreement, it might be necessary for you to install further equipment, and it would certainly be necessary to pay the $.10 per month per set, which now amounts to $100, and take into account the depreciation and interest upon investment, it would hardly seem that the apparent profit of $20 per month would not be more than used up.

Taking all this into consideration, together with a close analysis of the contract, which shows everything of benefit to the Hudson River Co., and nothing of benefit, and certainly much of detriment, to the Orange County Telephone Co., in that it is limited in its development, I should certainly strongly advise against an execution of the contract.

intuition that they have an axe to grind or they would never make you the offer they have, and if you accept it, you are dead sure to get that axe in the neck.

To-day your company is looked upon everywhere as one of the Independents whose Board of Directors are composed of men of honor, and it has been an inspiration to others struggling for relief from the exactions of the monopoly. The same confidence and respect your stockholders and directors have enjoyed at home, has spread to the entire Independent telephone field, and you are regarded as one of the bulwarks in the Independent ranks. You occupy a position which is known to be impregnable, and every one knows that you have the monopoly under your feet. Now, if you will surrender for what may appear for the moment as a temporary advantage, what can you expect of those who have been building on their faith in your integrity. There is an element known to the business world as *integrity* which is regarded among men of honor as beyond price, and I am not prepared to believe that your stockholders and directors will disregard this priceless heritage and surrender the exalted positions they have gained in the Independent field, when they come to make their final decision.

Little remains to be said in addition to Mr. Reynolds' review of what happens to Independents who ally themselves on any basis with Bell telephone companies. But there is a further object lesson in an analysis of the contract that was submitted by the Bell people to the Middletown company. Such an analysis was made by Mr. Frank B. Vermilya, of the New York City law firm of Sumerwell, Shoup & Vermilya, to whom Mr. Ramsdell submitted this contract. Mr. Vermilya's opinion demonstrates conclusively that even in its simplest dealings, the Bell is tricky and unreliable, and that it always lays it traps so that in the end it is certain to engulf any Independent company that may be short-sighted enough to enter into dealings with it.

The final outcome of the Bell's effort to entrap the Middletown company will not be determined until January 19th, when the matter will be submitted to the sotckholders at their annual meeting. Unless the majority of the stockholders are unusually stupid, it should not be difficult to forecast the result.

Not alone decency and good citizenship, but ordinary business foresight must dictate a course that will steer clear of any alliance with the Bell. Any company that has grown as has the one in Middletown surely has no sound commercial reason for entering into an arrangement with a competitor when it has virtually driven it out of business. When it began operating in Middletown in 1897, the Orange County Company had 296 subscribers. To-day it has 1,000.

IN THE OPERATING FIELD.

MEETING OF PENNSYLVANIA ASSOCIATION.

AS the result of a recent meeting of the Pennsylvania State Independent Telephone Association, held in Philadelphia, assurance was given that within the next three months direct connection will be had between this city and Kansas City and St. Louis over the lines of Independent companies. This marks another step in the progress of the Independent companies, inasmuch as these points, when connected, will be the farthest Western connections of the companies that are fighting the Bell Telephone Company.

The Eastern Traffic Association, which is composed of representatives from all Eastern Independent telephone companies, held a meeting and the universal tolls which have been prevailing for long-distance business over all the lines the past year were ratified. The States represented included Pennsylvania, New Jersey, Delaware, Maryland, Virginia, West Virginia and Ohio. Of this number the last three sent representatives for the first time. The Pennsylvania Association has been in existence three years.

INTER OCEAN EXTENDS LONG-DISTANCE LINES.

THE Inter Ocean Telephone Company, of Buffalo, N. Y., is at the present time engaged in a number of extensions to its long-distance lines that will eventually connect with Independent circuits, reaching points as far distant as St. Louis.

Buffalo is now in touch by that system with all the towns between Lake Erie and the Hudson River. The Southern Tier towns as far East as Binghamton, including Watkins and Penn Yan, as well as Hornellsville, Olean, Salamanca and Jamestown, are speedily to be united with the same circuit. Lines are up between Buffalo and Erie which already give an excellent service with Ohio and Western Pennsylvania points.

HOME COMPANY OF BLOOMINGTON, ILL., ISSUES NEW DIRECTORY.

THE Home Telephone Company, of Bloomington, Ill., has recently issued a new directory, dated December 1, which illustrates the growth of this progressive company. Between the time of going to press and the date of issue there were forty-one new subscribers to the local exchange. Besides the subscribers to the Bloomington exchange there are lists for fourteen surrounding towns and villages, including a list of McLean County toll stations. This company gives direct connections over copper metallic lines of the Interstate Independent Telephone and Telegraph Company to over five hundred towns in Illinois, Iowa, Indiana and Missouri. The McLean County Telephone Company, a list of whose stations is given, reaches 158 different toll points direct and a much larger number of more distant points over other companies' lines.

MAYOR OF LEBANON (IND.) VETOES BELL FRANCHISE.

MAYOR ROSS, of Lebanon, Ind., has vetoed the ordinance recently passed by the council granting the Central Union Telephone Company a franchise to do a local business in Lebanon. The mayor objected to the ordinance because it failed to limit the price of the service, and is opposed to placing the people at the mercy of a greedy corporation. The people are very well satisfied with the service of the local company, and the council is being criticised for granting the ordinance. The quiet manner in which the ordinance was put through is regarded with suspicion. Another ordinance will be introduced and a lively fight is anticipated.

FRANKLIN (IND.) OPPOSED TO BELL.

THE Central Union Telephone Company has asked for a franchise to do a local business in Franklin, Ind., and the application has aroused a storm of opposition. The Franklin Telephone Company has over 800 telephones in operation, and patrons talk all over the county without toll or fee. The rate is $1.00 and $1.50 a month for residence and business telephones, respectively. The local company erected a substantial building and occupied the field at a time telephones were not so much in demand, and is now giving patrons connection with seven Independent switchboards, together with many cities in the State. The granting of a franchise and establishing of an opposition service is opposed by the citizens as unjust, unnecessary and uncalled for. A lively fight is anticipated when the ordinance comes up for passage.

MAYOR OF EVANSVILLE, IND., CALLS MEETING.

MAYOR COVERT, of Evansville, Ind., has called a meeting of the city council, city officials and representatives of the Cumberland Telephone Company with a view of effecting a compromise agreement whereby the telephone question can be settled. Mayor Covert has carefully avoided hinting as to what he expected to be the final outcome of the matter or as to how he would stand when the matter was brought up for discussion. The company, it is understood, has made overtures for a settlement of the telephone question, and it is for the purpose of considering these overtures that the meeting was called. The public will be invited to the meeting.

INDEPENDENT EXTENSION IN THE STATE OF WASHINGTON.

PLANS for extensions that will cost $300,000 and which will practically cover the entire Puget Sound country have been perfected by the Independent Telephone Company, of Seattle, Washington.

It is the idea of the corporation to gradually invade the entire Pacific Coast field for long-distance service, and to this end lines are about to be constructed to several points to the northward of Seattle. The plans that are at present in process of consummation provide over 100 miles of additional lines for the company.

A short time ago the company acquired a controlling interest in the Citizens' Independent Telephone Company, at Port Townsend, and recently perfected arrangements whereby the wires of the Seattle company could be connected with those of the Angeles Telephone and Telegraph Company, at Port Angeles. The former company's lines have a long-distance connection with Port Hadlock, Seguim Junction, Glinn, Fort Washington and several farmers' lines. The latter has an exclusive field at Port Angeles with over 300 subscribers.

The Independent Telephone Company is preparing to build to Dungenness west to connect with the Port Angeles exchange, and from there south to Seattle. The material is already purchased to build long-distance lines from Port Townsend here and to connect Port Angeles and Port Townsend.

The line from Seattle to Port Angeles will be partly cable, running across the bay at Bainbridge Island.

TRI-STATE WINS CONTRACT OVER BELL.

THE Tri-State Telephone Company, of Pennsylvania, has closed a contract with the West Penn Railways Company for the installation of the Tri-State telephone in the general offices at Connellsville and all over their system. The contract will go into effect on January 1, 1905. This will result in the supplanting of the Bell telephones. The West Penn Company has had a private exchange in its general offices in Connellsville, and the resident telephones of officers and employees have been about equally divided between the Bell and the Tri-State.

The West Penn Company decided to adopt the Tri-State, as it has been found to be up to the standard, both for long distance and local service. Beginning January 1 all its offices will be equipped with long-distance Tri-State telephones. Besides all power houses and substations from Pittsburg, McKeesport, Jeannette, Greensburg, Irwin, Manor, Youngwood, Scottdale, Connellsville, Dawson, Uniontown and McClellandtown, as well as residences of all officials and employees.

At the start about 80 telephones will be installed, but this number will be increased from time to time, as business demands.

FINE SHOWING OF CUYAHOGA.

THE Cuyahoga Telephone Company, of Cleveland, in its November statement, shows a gross increase of $18,121.41, and an increase in net earnings of $6,765.43 over the corresponding month of last year. This is an exceptional showing and speaks well for the prospective value of this company's securities. It is noteworthy in connection with this statement that all the other subsidiary companies of the Federal Telephone Company, of Cleveland, show net increases in every instance but one, and that is due to a large amount of construction work done during the past month.

BIG DEMAND FOR INDEPENDENT TELEPHONES IN DUBUQUE.

PRESIDENT VIC STEVENS, of the Dubuque, Iowa, Telephone Company, states that there is a heavy demand for the telephones of his company, which has connections with the Tri-State and Inter-State Telephone Companies. This demand comes from business men and farmers in the southern part of Grant County, Wis., and the northern part of Jo Daviess County, Ill., and from farmers in the intermediate territory. Among the places where telephones have been put in and connection made with Dubuque, and places in Grant and Jo Daviess Counties are the Three Mile House, Happy Corners, Fairplay and Lake Frentress. A gang of men is now at work in Cuba City and vicinity, installing instruments, and others will be put to work as soon as possible in Galena and other towns in the northern part of Jo Daviess County, so that the whole territory may be covered as soon as possible with Independent lines.

SOME TELEPHONE FACTS

FOR YOU TO REMEMBER.

75 percent of telephone subscribers NEVER talk over a TOLL line.

97 percent of telephone subscribers NEVER talk outside of a radius of 35 MILES from HOME.

SOUTH BEND and MISHAWAKA is the commercial center of 95 percent of all telephone users within the 35 mile radius of these cities.

The INDEPENDENT Telephone Companies have 20,000 subscribers in this territory, and therefore do 95 percent of the telephone and toll business in this commercial territory.

The Bell Company has about 1500 telephones in the same territory and therefore does ONLY 5 percent of the telephone business of South Bend and Mishawaka.

The Home Telephone Company reaches 3500 subscribers in St. Joseph county.

No. of Telephones Installed.	Home Phones.	Bell Phones.
In the State of Indiana	155,000	45,000
13th Congressional District	10,000	1,383
St. Joseph County	3,354	1,030
South Bend	2,862	900
Mishawaka	492	125

The above statement is the gist of a circular issued by the South Bend Home Telephone Company, of South Bend, Indiana, showing the remarkable development made by the Independent telephone movement in Indiana. As a statement of facts, it is clear and concise, proving beyond a question of doubt the superiority of the Independents over the Bell.

As an aid to those Independent Companies which are menaced by the Bell interests, THE AMERICAN TELEPHONE JOURNAL *has had the above statement reproduced, and will be pleased to furnish electrotypes at cost (80 cents each) to be used for printing circulars, or in any other way they may think best. To those who may desire to get the circulars printed without the trouble of having an electrotype made,* THE AMERICAN TELEPHONE JOURNAL *will quote a price of $1.50 a thousand, f. o. b. New York.*

PRINCETON, IND., INDEPENDENT CO. TO ERECT NEW BUILDING.

THE Independent Telephone Company, of Princeton, Ind., will erect a new exchange next spring. The specifications call for a two-story building of pressed brick with Bedford stone trimmings. Additions will be made to the switchboard and increased terminal facilities will be installed. The cost for the building will be about $8,000.

The long-distance service of the company was greatly augmented recently by the completion of a circuit to connect with the Knox County Home Telephone Company, of Vincennes. This connection gives the company long-distance service to all the important points in Ohio, Indiana, Illinois, West Virginia, and Pennsylvania, and as far south as Louisville, Ky.

Ultimately this service will be extended to reach points in Kansas, Missouri and other Western States.

COLUMBIANA CO. INSTALLS NEW SWITCHBOARD.

A NEW switchboard is being installed in the plant of the Columbiana Telephone Company and the officers of the Federal Company in Cleveland report that the outlook for that company during the next year is very bright. When the plant was first put in the rates were made too low and the officers decided to raise them. Some of the business men in the territory objected, and there was considerable trouble for a while. The company now has its new rates firmly established and nearly as many telephones as it had before and is increasing rapidly.

IN THE MANUFACTURING FIELD

"SUCCESS LIES IN THE KNOWLEDGE OF OUR TOOLS."

NEW DEAN PORTABLE DESK STAND.

THE new desk stand manufactured by The Dean Electric Company is a radical departure from the time-honored method of construction. It is made in the most substantial manner possible, the inner framework being pressed and drawn from heavy sheet steel, instead of the usual castings. The external design is along graceful and simple lines, while the finish is beautiful and lasting. The upright is covered with a thick, polished, hard-rubber tube and all of the remaining exposed portions are heavily nickel plated.

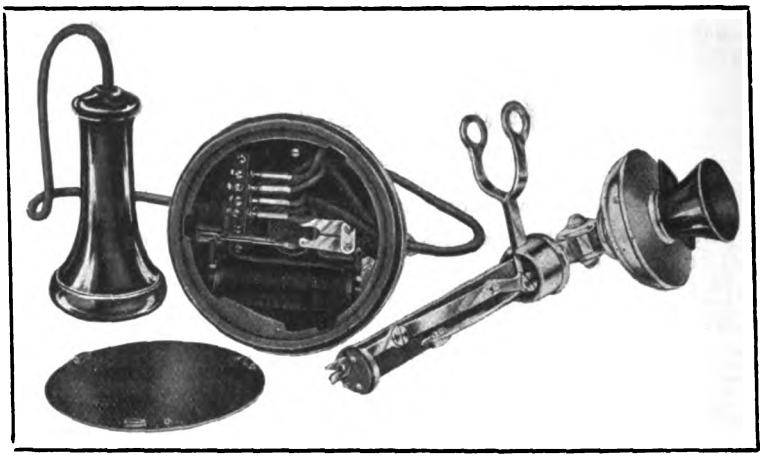

Fig. 2. Dean Desk Stand Opened as Shown Without the Use of Tools.

The hook switch is one of the most novel features of the Dean desk stand. The contact springs, which are of the same as those used in the standard Dean hook switch, are mounted edgewise within the base so that the platinum contact points are open for inspection by simply removing the base cover. The motion of the hook proper is transmitted to the contact springs by a simple intermediate lever, which, together with its actuating or main spring, are mounted on a steel frame. This steel frame is locked in place within the upright tube by a spring catch, which can be released from the bottom of the stand when the base cover is removed. The transmitter is mounted on the top of this steel frame and its circuit carried to spring contacts within the base, thus allowing the entire mechanism concealed within the upright to be removed without disturbing the wiring. The base cover is held in place by a bayonet lock and spring catch, thereby making it possible to quickly open up the stand so as to get at all of the working parts without the use of tools, as shown in Fig. 2. The cushion protection, provided on the bottom of the stand, is left in place after the base cover is removed, so that there is no danger of marring the desk woodwork.

Fig. 1. Dean Desk Stand.

An entirely new feature incorporated in the Dean desk stand is the interchangeable circuit plate. All of the talking circuit apparatus, excepting the transmitter and receiver, is mounted on a metal plate and completely wired so as to form a unit, as shown in Fig. 3. These units are interchangeable and are arranged for local battery and common battery circuits, the remainder of the desk stand, excepting the transmitter, being the same for both services. Thus, in making a change, it is only necessary to replace the circuit plate with the one containing the desired new circuit. Special tools are not necessary, as the plates are complete in themselves and are held in place by three screws. Exchanges contemplating a change from local to common battery at any future time will fully appreciate this new feature.

All of the parts entering into the circuit of the Dean desk stand are concealed and thoroughly insulated, so that there is no chance for the subscriber to receive a shock while using the instrument.

The steel framework and other parts subject to corrosion are carefully plated with copper. The base is provided with a nickel plated, heavy brass covering which will not become dented by severe use. The new Dean "balanced Wheatstone bridge type" common battery talking circuit is especially adapted for mounting in a desk stand, as, outside of the transmitter and receiver, it contains only a single coil. The hook switch has only one contact, while the cord necessary to connect the stand to the desk set box requires only two conductors. All of the circuit apparatus, excepting the transmitter and receiver, are mounted on a circuit plate, as shown in Fig. 3, which is interchangeable with the local battery circuit plate. The use of a one-point hook switch and a two-conductor cord reduces the maintenance of this stand to a minimum.

The local battery or magneto stand is arranged similar to that of the common battery stand the induction coil and contact springs mounted on a circuit plate, which is interchangeable with that of the common battery stand.

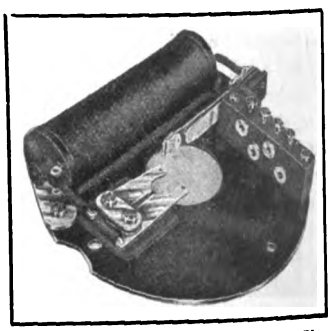

Fig. 3. Interchangeable Circuit Plate Mounted on Base of Desk Stand and Arranged for Either Local or Common Battery.

The bell box used with the common battery stand is made from pressed steel with an enamel finish. It contains only the signaling apparatus, consisting of a ringer and condenser, as all of the talking apparatus is located in the stand. The magneto bell box is made from quartered oak or walnut and contains the ringer and generator.

THE MILLER ANCHOR COMPANY, of Norwalk, Ohio, reports large sales of its anchors to the following companies: The Cumberland Telephone and Telegraph Company, Nashville, Tenn.; The United States Long Distance Telephone Company, Cleveland, Ohio; and the New York and New Jersey Telephone Company, New York. This is sufficient evidence of the good qualities of this type of anchor, since the companies above mentioned

IN THE MANUFACTURING FIELD

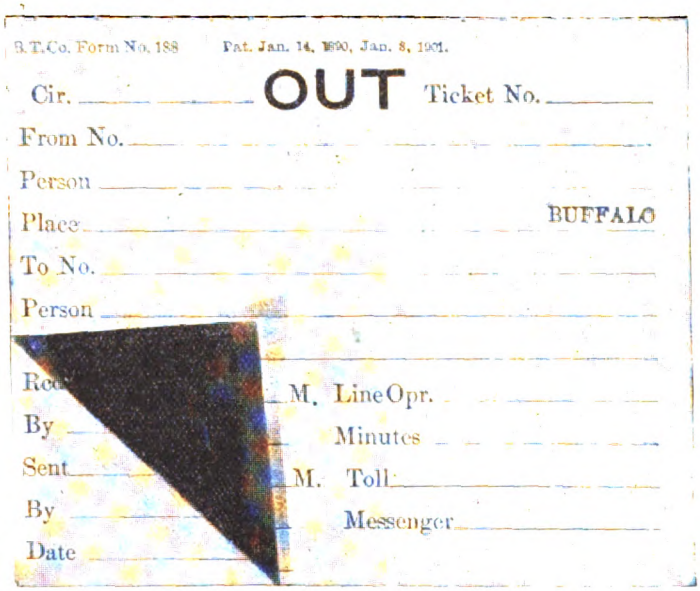
"SUCCESS LIES IN THE KNOWLEDGE OF OUR TOOLS"

are among the largest in the industry. The Miller Company will be pleased to furnish descriptive matter and prices upon application and to give all further information desired.

MANIFOLDED TOLL TICKETS.

ONE of the most irksome problems which faces the general manager is the constant necessity of adjusting questions relating to the toll line charges. Customers are exceedingly prone to question the validity of the charge, both as to the time spent in conversation and the rates assessed. The labor to which the operator is subjected in the making of toll line tickets is an important item, and unless duplicates are preserved there is no means of substantiating bills for service.

The General Manifold Company is placing upon the market a device which will be welcomed as an improved solution of the problems which have thus risen. The toll ticket consists of a piece of paper which is divided in the center by a perforated line, so that it may readily be torn into two pieces, and the halves are printed in duplicate bearing the same legend. On the reverse side of the left hand half the ticket is carbonized, so that when the operator writes upon the outside of the sheet, a carbon copy is automatically made upon the inside. At the end of each day the toll tickets may be collected and torn in two, one copy being sent to the subscriber while the fac-simile is retained by the telephone company. By this means an original autograph copy of all messages transmitted is obtained with no more expenditure of labor than is necessary to make the original ticket.



Manifold Ticket made by General Manifold Company.

THE CARBOLINEUM WOOD PRESERVING COMPANY, of Milwaukee, Wisconsin, has issued a pamphlet describing "Avenarius Carbolineum Wood Preservative," a wood preservative of the highest grade. The pamphlet contains letters of recommendation from some of the largest users of poles in the country, including railroad, telephone and telegraph companies. A comparative illustration of the value of this preservative is shown in two pictures of wooden logs, one of which, after twenty years' use, is still in good condition, having been treated with this preservative; the other, although only in use five years, is badly decayed where it was below ground. An analysis of the preservative is given, together with directions for its use. This preservative will prevent checking and warping of woodwork, dry rot, and decay of any sort. It is easy to apply and does not contain volatile or dangerous ingredients. It is a strong antiseptic and is free from all poisonous matter of any description. The company will furnish more detailed information upon request, together with this pamphlet.

THE T. & A. SELECTIVE CALL COMPANY, of Geneseo, Ill., manufacturers of selective call apparatus for relay party lines, has engaged Mr. S. G. Fletcher as shop superintendent. Mr. Fletcher has had a wide experience with numerous tool companies in Chicago and vicinity, and is eminently fitted for the requirements of his responsible position.

COOK GETS COLUMBUS.

FRANK B. COOK has received from the Automatic Electric Co. an order for a complete distributing and protector frame for the exchange of the Citizens' Telephone Co., at Columbus, Ohio. The capacity of the frame is to be 8,100 pairs, and it will be equipped with 8,000 pairs of Cook's No. 444 self-soldering protectors. This installation is especially worthy of note, as it is the largest protector board that has been installed for several months. Cook is particularly pleased with the order from the fact that it shows the manifest confidence of the largest exchanges and manufacturers in the country in the superiority of his self-soldering protectors.

Other orders which Cook has received from the Automatic Electric Co. are as follows: for the Delaware Telephone Co., Wilmington, Del., a type L frame with a capacity of 2,500 pairs, equipped with 2,000 pairs of No. 444; for the Solvay Process Co.'s System, Syracuse, New York, 200 pairs; for the Home Telephone Co., Los Angeles, Cal., a 900-pair addition to the East Exchange; Home Telephone Co., Santa Monica, Cal., type L frame, 500 capacity, equipped with 360 pairs; for the Ocean Park Exchange, 500 pairs capacity, equipped with 300 pairs; for the Sawtelle Exchange, 300 capacity, equipped with 160 pairs.

THE B. R. ELECTRIC AND TELEPHONE MFG. COMPANY, of Kansas City, Mo., has issued Catalogue No. 5, which contains a complete list of telephones and accessories, construction material, tools, etc. Among the telephones listed are seven different types of magneto instruments to meet any and all classes of service. Switchboards for toll and subscribers' lines, as well as for farmer or rural lines, are listed and can be furnished to meet all requirements. Among the accessories are linemen's testing sets, generators, ringers, extension bells, transmitters, receivers, pay station coin collectors; wire, iron, copper, twisted, insulated; cables, connectors, terminals, distributing frames, cleats, expansion bolts, lightning arresters, tape, solder, testing instruments, pole changers, tools, linemen's accessories, torches, reels, construction tools, and material of every description. The catalogue also contains a short treatise on line construction which will be of interest to the readers. This company is in an exceptional position to make prompt and quick shipments and earnestly desires to hear from all parties interested.

THE CONN. TEL. & ELEC. CO., INC., of Meriden, Conn., has filled a long-felt want for over-loaded country lines in its new non-interfering ringing device. This device is especially designed for stopping the listening upon a heavily loaded bridging line. It makes no difference how many receivers are off the hook, you can

IN THE MANUFACTURING FIELD

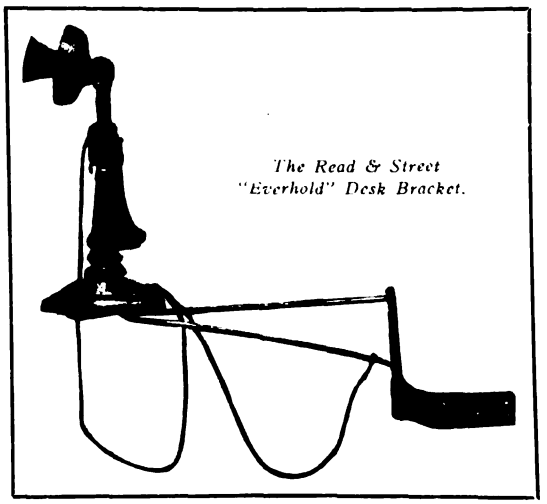
"SUCCESS LIES IN THE KNOWLEDGE OF OUR TOOLS"

ring through them all. The company will furnish particulars of this system upon request.

SWITCHBOARD LAMPS.

THE Howard Miniature Lamp Company, 221-227 Canal street, New York, and 183 Lake street, Chicago, is placing upon the market a wide variety of telephone lamps which are so designed as to fit any of the jacks or sockets commonly found upon the switchboards of well-known manufacturers. In a new catalogue which this company is distributing, these lamps are described and illustrated in a thorough manner, but on account of the diversity of the different types it is impossible to detail all the different ones, and therefore those interested should write, giving full particulars of their requirements.

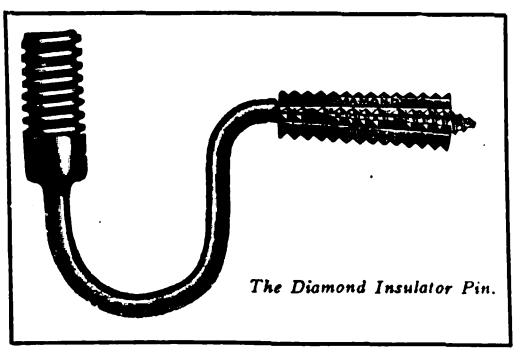
Switchboard lamps require so much care in their design that it is absolutely necessary that all the details incident to their ultimate use are necessary to secure the best results. This firm is in an exceptional position to furnish any and all styles, and will be pleased to confer with all interested. The catalogue lists lamps varying from .2 to .5 candle-power, with working voltages from 4 to 40, and current consumption from .05 to .36 amperes. Special designs for voltages up to 60 will be quoted upon request, and any other information will be cheerfully furnished by the company.



The Read & Street "Everhold" Desk Bracket.

A NEW DESK BRACKET.

FOR quite some time it was realized by exchange managers that the cost of maintenance upon desk telephones was way out of proportion when compared with that necessary for wall instruments. The reason was obvious, a desk telephone could be easily upset, and severely damaged by clumsy handling. The partial solution to this vexatious and expensive problem came with the introduction of desk brackets. Soon there were several types upon the market, each having good points, but it remained for the firm of Read & Street, 48 N. 11th street, Philadelphia, to reach the acme of simplicity and neatness in design in their "Everhold" telephone rest. Its commendable features are many, its faults may be put down as a minus quantity. From the accompanying illustration a good general idea can be obtained of the device. It will be noted that there are no screws or other clumsy attachments necessary to fasten the telephone to the holder, the spring formation of the clamp being so arranged as to enable a desk instrument to be put in place without the use of any tools whatever. It is the lightest and most substantial desk bracket on the market, and having no wearing parts to get out of adjustment, it offers the most economical type of bracket so far devised. The holder is heavily nickeled and presents a graceful appearance. Another special feature is that on account of its spring character it does not convey vibrations to the transmitter as readily as the solid arms, and its use is therefore very advantageous in mills or other buildings subject to vibrations. The firm will be pleased to furnish full particulars and prices upon request.



The Diamond Insulator Pin.

THE NATIONAL CARBON COMPANY, Cleveland, Ohio, was awarded the "Grand Prize" for batteries at the Louisiana Purchase Exposition. It manufactures the Columbia dry cell and therefore it is the first and only "Grand Prize" dry cell in existence. This company has experienced an extraordinary sale for its Columbia cell, and claims that telephone companies are using more of this type of battery than all other makes combined. Further information about all classes of batteries will be gladly furnished upon request.

DIAMOND INSULATOR PIN.

THE New Jersey Foundry & Machine Co., of 9 Murray street, New York, has recently placed on the market an insulator pin, shown by accompanying engraving, which will be of interest to telephone, telegraph, electric light and power, signal companies, and others having occasion to fasten insulators to brick, stone, concrete, or other masonry.

The pin itself is of cast iron, with threads to fit standard glass and porcelain insulators, a bolt being cast in the base and made with a lag screw thread to fit the Diamond Expansion Shield, which will secure a positive hold in any solid material, making a simple, strong and economical fastening. The bolt can also be furnished for use with regular oak or locust pins.

The shank of the bolt can be furnished straight, with a Spanish hook, or any angle desired.

A large number of these insulator pins are being used in the subways of the Interborough Rapid Transit Company, of New York, for carrying wires under station platforms.

The pins are manufactured by the New Jersey Foundry & Machine Co., of 9 Murray street, New York, who will furnish any further information to parties interested upon request.

THE MODEL ELECTRIC COMPANY, 204 North Main street, Burlington, Iowa, has a very attractive proposition in apparatus to offer to telephone companies. This firm is engaged in the manufacture of a type of telephone material that bids fair to quickly place it on a plane with the largest and oldest manufacturers in the country. Telephones and accessories for all classes and conditions of use are offered at a price which heretofore has been considered incompatible with good workmanship, yet so much time and thought has been put into the design of the various parts that increased economy in manufacture is attained, and thus the instruments can be sold at the prices quoted. Every part is designed for the maximum of efficiency by expert mechanics, and before shipping is submitted to the most critical tests to discover any possible defects. A sample instrument will be sent prepaid on approval by the company. This offer in itself proves the quality of its apparatus, because it is certain to be submitted to severe tests.

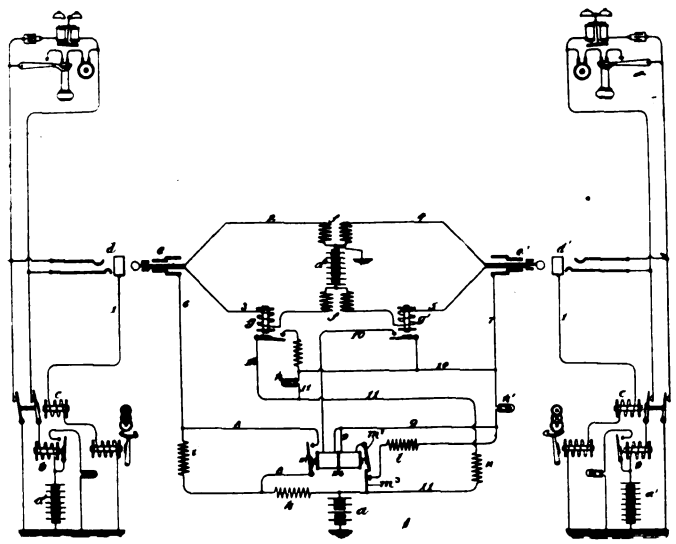
TELEPHONE PATENTS

TELEPHONE SERVICE METER.

F. R. McBerty, Evanston, Ill., patents (No. 777,217) an improved form of service meter, and assigns to the Western Electric Company.

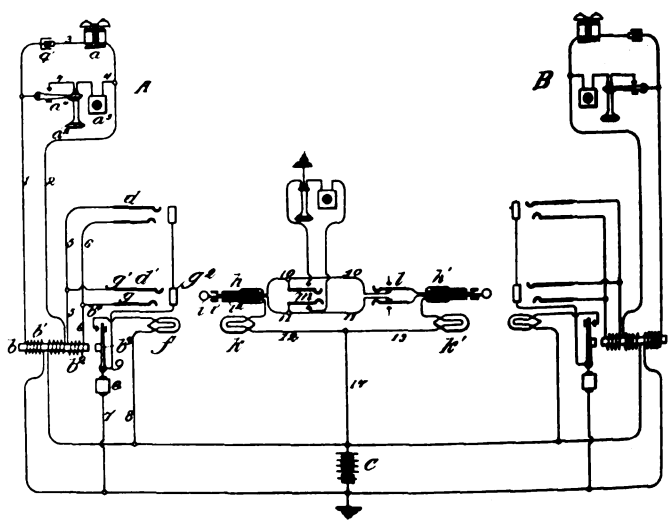
This patent is a further development of Re-issued Patent No. 12185. Circuit is shown in the accompanying illustration. So far as the subscriber's line is concerned it is arranged in the usual manner, excepting that additional magnet and service meter is added to conductor *1* extending through the cut off relay *C*. The cord circuit has the position of the supervisory lamp h_1 changed, and four resistances, *i*, *k*, *l* and *n*, operate in conjunction with



the relay *m*. The operation is as follows: When the operator answers, the local circuit *6 1* is completed. The shunt *8* about coil *i* being open, the current in circuit *6 1*, while sufficient to excite the cut-off relay *c* of the calling line, is inadequate to move the armature of the service meter. Likewise current through *7 11* and conductor *1* of called line is sufficient to excite the cut-off relay; but by reason of the resistance coils and of the high resistance of the signal lamps it is insufficient to operate the service meter of the called line. The current tends to excite the lamps *h* and h^1. Simultaneously with the closure of the local circuit in the answering plug and spring jack of the calling line current is permitted to flow in the line from the source a^2, which excites the supervisory relay and shunts the lamp *h*. Hence lamp remains dark. But the lamp h^1 is lighted. When the telephone at the called station is taken for use, the relay *g* closes the shunt circuit *10* of lamp h^4, excites relay *m* and causes it to close its armature m^1 and m^2 against their front contacts. The movement of lever m^2 breaks the direct path of current from the battery through the lamp h^1 and completes a new circuit through the other winding of magnet *m*, which thereafter maintains the excitement of the magnet independently of the shunt *10*, and subject only to the completion of the circuit *7 9 1* through the local contacts of the calling plug and the spring jack of the called line. The movement of the switch lever m^1 against its contact produces in the circuit *6 1*, through the answering plug and local conductor of the calling line, a current sufficient to operate the service meter of that line, which is thereby caused to register the completed connection. The service meter is then held in its attracted position until the circuit is broken. Both signal lamps *h* and h^1 meantime remain subject to the controlling shunts *12* and *10*, respectively, so that they indicate to the operator the condition of the telephone switches. The magnet of the service meter associated with the called line will not receive sufficient current for its actuation, by reason of the high resistance included in circuit therewith. It is customary for users of telephones to give a number of orders for connection with wanted lines in quick succession, and the operation of making the required connections is greatly facilitated by leaving the answering plug in the spring jack of the calling line, removing the calling plug only from the spring jack of the called line upon the flashing of the calling subscriber's signal lamp *h* and inserting said plug in the spring jack of another wanted line.

COMMON BATTERY SWITCHBOARD CIRCUIT.

C. E. Scribner, of Chicago, Ill., patents (No. 772,833) an improved common battery switchboard circuit and assigns to the Western Electric Company. In common battery switchboards it is common to insert repeating coils in the plug circuits. This arrangement is open to the objection that the signal relays are shunted by the repeating coil and sometimes rendered inoperative. The object of the present circuit is to improve in this respect. The substations are represented by *A* and *B*, connected with the central office by conductors *1* and *2* that extend through the winding *b'* of the repeating coil *b* and thence to the battery *c*. This repeating coil *b* contains another winding *b2* which extends to the springs of the jacks by the conductors *5* and *6*. The core of the repeating coil is provided with an armature *b3*. When the coil is excited this armature closes the contacts *b4* and illuminates the line lamp *f*, the circuit being from the battery *c* through conductor *8*, lamp *f*, armature of relay resistance coil *e*, conductor *7* to battery. When the operator inserts the plug *h*, a new arrangement of local circuits is formed, there being a



path from the battery through wires *14* and *12* to sleeve *i2* of the plug, thence to the ring of the jack *g2* through wires *7* and *9* to the battery *c*, then the supervisory lamp *k* is in parallel with the line lamp *f* and both in series with the resistance *c*. The lamps and the resistance are so proportioned that under these circumstances the lamps do not light. As soon as the receiver is returned to the hook, the relay *d* is demagnetized, its armature falls back and the supervisory lamp *k* is illumined because the shunt due to the line lamp *f* is removed.

IMPROVED TELEPHONE SYSTEM.

Charles Adams-Randall, Boston, Mass., patents (No. 777,324) an improved telephone system. In this invention the inventor proposes to improve telephonic transmission by arranging condensers of sufficient capacity at the ends of the telephone line so that it is unnecessary to employ either a ground return or a metallic conductor to complete the circuit.

THE WEEK'S MESSAGES

FINANCIAL.

CEDARVILLE, ILL.—The capital stock of the Cedarville Telephone Co. has been increased from $15,000 to $40,000.

OSSIAN, IND.—The Uniondale Rural Telephone Co. of Ossian has increased its capital stock from $1,300 to $13,000.

REPUBLIC CITY, KAS.—The Republic City Telephone Co. stockholders voted for a loan not exceeding $2,000 to be used in building new lines.

CENTRALIA, MO.—The Central Telephone Co. has increased its capital stock from $6,000 to $30,000.

CEDARVILLE, O.—The Cedarville Telephone Co., of Cedarville, has recently increased its capital stock from $15,000 to $40,000.

CHESTER HILL, O.—The People's Telephone Co., of Chester Hill, has increased its capital from $5,000 to $15,000.

FRANCHISES.

FULLERTON, CAL.—Application has been made to the Board of Trustees of the City of Fullerton for a franchise for a period of fifty years to erect, maintain and operate a telephone system.

WEST PALM BEACH, FLA.—J. R. Anthony, Jr., and others have applied for a franchise to operate a telephone system at Palm Beach.

MOULTOH, IA.—The Farmers' Mutual Telephone Co. has been granted a franchise.

HOBART, OKLA.—The Washita Valley Telephone Co. has been granted a franchise at Hobart.

ROCHESTER, MINN.—The Tri-State Telephone Co. has been granted a twenty-year franchise.

SEATTLE, WASH.—The Independent Telephone Co. has applied for a franchise, which was granted to them last Thursday, covering every road in the country.

ELECTIONS.

BLOOMINGTON, ILL.—At a recent meeting of the McLean County Telephone Co. the following officers were elected: President, F. Y. Hamilton; vice-president, William H. Johnson; secretary, Henry Thobro; treasurer, George Purr.

CRAWFORDSVILLE, IND.—The Co-Operative Telephone Co. at its annual meeting elected the following directors: David Remley, George Wasson, Clarence Williams, Perry Stump, and John Sewers.

BOONE, IA.—At the annual meeting of the Dodge-Harrison Telephone Co. the officers for the coming year were elected as follows: President, Fred Hein; secretary, Maurice Garvey; treasurer, Adam Moeller.

KALONA, IA.—At a recent meeting of the Kalona Mutual Telephone Co. the following officers were elected: William Rawson, president; John Durst, treasurer; U. C. Smith, secretary; Dr. Kison, W. G. Brooke, Dr. Allen and Harry McNulty, directors.

LEMARS, IA.—At the annual meeting of the LeMars Telephone Co. the following officers were elected: A. C. Colledge, president; I. S. Mahin, treasurer and secretary.

BUXTON, N. D.—The Red River Valley Telephone Co. recently held their annual meeting, and elected the following officers: President, T. J. Smith; vice-president, P. M. Paulson, secretary, treasurer and general manager, F. H. Hagen.

ST. ALBANS, VT.—At a recent meeting of the Franklin County Telephone Co., the following officers were elected: President, Jasper N. Keller, Boston, Mass.; vice-president, J. H. Abbott, of Gouverneur, N. Y.; treasurer, E. S. Willard, of Boston, Mass.; secretary, S. W. Flinn, of St. Albans; auditor, E. W. Longley, of Boston, Mass.

COMBINATIONS.

FT. WAYNE, IND.—The Leavenworth Telephone Exchange has been purchased by George W. Beers, of this city. It is Mr. Beers' intention to reorganize the exchange and make it thoroughly modern. He will spend $150,000 in improvements.

MINNEAPOLIS, MINN.—A syndicate of Minneapolis men, with S. S. Thorpe at the head, has purchased the Mississippi Valley Telephone Company's property in Iowa for $400,000. The property includes extensive exchanges at Muscatine, Burlington, Keokuk, Madison and Wappello, and were formerly operated by J. C. Hubbinger. The name of the company will remain the same, S. S. Thorpe to be president, and Thomas Peebles, secretary and general manager.

OLEAN, N. Y.—A. V. Hurd, of Olean, has purchased the Home Telephone Co., of Port Allegheny, Pa.

EGAN, S. D.—Mr. G. W. Moit, owner of the Egan Telephone, has bought the Flandreau system, and is planning to make one line of the two rural lines.

PENDLETONVILLE, TEX.—Mr. J. V. Moore and son have bought out the Pendleton Telephone Co., and will shortly put up lines along the various public roads.

NEW COMPANY NOTES.

WASHINGTON, D. C.—The Telegraph & Telephone Auxiliaries Co., of Washington, has been incorporated with a capital of $300,000 by F. R. Austin and others.

ALEXIS, ILL.—The Alexis Telephone Co., of Alexis, has been incorporated with a capital stock of $5,000.

CHICAGO, ILL.—The Western Telegraphone & Telegraphex Co., Chicago, Ill., has been incorporated with a capital stock of $60,000. The incorporators are R. P. Jack, Herbert W. Danforth and W. I. Irwin.

FISHER, ILL.—The Grangers Mutual Telephone Co. has been incorporated, and has recently increased its capital stock from $15,000 to $20,000.

GRAYVILLE, ILL.—The Westfall Telephone Co., Grayville, Ill., has been incorporated with a capital stock of $4,000 by W. F. Westfall, Claude O. Ellis and Nathan March.

TEMPLE HILL, ILL.—The Egyptian Telephone Co., of Temple Hill, has been incorporated with a capital stock of $2,500.

AMBOY, IND.—The Amboy Telephone Co., of Amboy, has been incorporated with a capital stock of $20,000 by N. W. King and others.

ELKHART, IND.—The Automatic Switchboard & Telephone Mfg. Co. has been incorporated with a capital stock of $10,000.

BELLAIRE, O.—Good progress is being made in the installation of the underground system of the Ohio Valley Telephone lines. The work has to be done rapidly to prevent the cement freezing.

PERSONAL.

NICHOLAS ARROWSMITH has been appointed district manager of the Morristown, N. J., telephone office of the New York & New Jersey Telephone Co.

J. E. HENDERSON has been appointed division superintendent for the Southwestern Telegraph & Telephone Co. at Fort Worth.

OBITUARY

JOHN C. JOHNSON, secretary of the Delaware & Madison Counties Telephone Co., died suddenly of apoplexy at his home at Muncie, Ind., at the age of sixty-one.

MISCELLANEOUS.

OTTAWA, ILL.—The Bureau County Independent Telephone Co. now has 3,200 telephones in use in Bureau county and the number is still growing.

BEDFORD, IND.—The Home Telephone Company's exchange was recently damaged by fire.

OTTUMWA, IA.—The Hudson Mutual Telephone Co. is negotiating for the lease of a United States circuit from here to Hudson.

WEBSTER CITY, IA.—A recent fire in this town did considerable damage to the Hamilton County Telephone Co.

MAYSVILLE, KY.—George Shaw, of Carlisle, representing an Ohio syndicate, is in this city to perfect an organization with the telephone companies whereby a full metallic service will be put in between this city and Louisville, going by way of Carlisle and Lexington. This will give Maysville communication with the Central Kentucky towns and will give Louisville an outlet to the north by way of this city and Portsmouth, O.

OWINGSVILLE, KY.—A company has been organized to build a telephone line from Moore's Ferry to Salt Lick, this county, a distance of five miles.

LEWISTON, ME.—The Lewiston & Auburn Telephone Co. has issued its first directory of subscribers to the new automatic system in Lewiston.

ALMA, MICH.—The Union Telephone Co. has had a great business during the past year throughout its territory. During the twelve months ending November 1st, they had installed 1,200 new telephones. A great many of these new subscribers are on rural lines, although in each of the towns where they have an exchange the number of subscribers have increased. At Alma the company has doubled in the past eighteen months.

FREMONT, NEB.—A meeting of farmers in this vicinity was recently held to make arrangements for the extension of the Fremont Telephone Company's lines into the rural districts.

FREDERICK, N. B.—At the semi-annual meeting of the New Brunswick Telephone Co., Hon. Mr. Thompson said the cost of repairing the wires after the late storm would cost about $10,000 or $15,000.

PORTAL, N. D.—The Clyde Telephone Company has commenced business here.

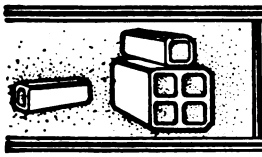
LOWER NEWPORT, O.—Surveyors for the Marietta Telephone Co. are surveying the proposed new line through here to Newport.

SALEM, O.—The Salem Township Rural Telephone Co. has its lines nearly completed, and within a few days the subscribers will be connected up with the switchboard of the Columbiana county exchange at Leetonia. The Salem township company has made arrangements with the Columbiana county lines for interchange service.

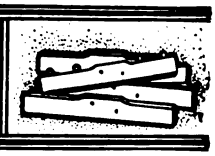
CALIFORNIA, PA.—The Union Telephone now gives service to 250 subscribers in California, Coal Center, Twilight and the surrounding country.

COGAN HOUSE, PA.—A number of citizens interested in the telephone line held a meeting to determine the terminus of the line and the section through which it would be installed.

NEWCASTLE, PA.—The Pennsylvania & Mahoning Valley Telephone Co. is to have an Independent telephone system connecting all points on the line.



New Construction in the Field



BESSEMER, ALA.—The People's Home Telephone Co. has completed a telephone line from Bessemer to Hawkins Springs, and will begin work on a line to East Bessemer. A 200-pair cable is being erected in the city to give the north side of the city a better service.

VENTURA, CAL.—The Home Telephone Co. has practically completed its outside work in Ventura. Over 100 miles of copper wires have been used in wiring the town.

ROCK ISLAND, ILL.—A telephone line is being built between Taylor Ridge and Edgington to connect with the local exchange of the Union Electric Telephone Co. at Edgington.

CEDAR FALLS, IA.—The United States Telephone Co. has installed a new switchboard in this village.

CENTERVILLE, IA.—The Mutual Telephone Co. is considering improvements and extension of its plant.

ESTHERVILLE, IA.—The Emmet County Telephone Company is contemplating extensive improvements.

INDUSTRY, KAN.—The Farmer's Telephone Company has begun the construction of a line from Buckeye to Upland.

SAVONBURG, KAN.—The Savonburg-Leanna Telephone Company will install a modern switchboard in local exchange.

SOUTH HAVEN, KAN.—R. W. Kemp, contracting engineer of Wichita, Kansas, has just completed an exchange for the Farmers' Mutual Telephone Company at South Haven, and has secured the contracts to build the mutual lines for the Chickaskia Mutual Telephone Company from Milan to Wellington, via Mayfield, and the Oxford Mutual Telephone Company from Oxford to Wellington, via Dalton. The lines when complete will connect with the Farmers' Mutual Company at Wellington and make a mutual system of over 2,000 subscribers.

STAFFORD, KAN.—The Larabee Bros.' Telephone Co., of Stafford, are preparing to install a new, up to date central energy system in the town of Stafford. Work has already been commenced and the new system will be in working order early in the new year. The best material obtainable will be used and the plant will be first class in every respect. The Stafford company will build a toll line west as far as Seward, where they will connect with the Larned Telephone Company's lines from Larned.

WELLINGTON, KAN.—The Anson Mutual Telephone Co. will build a rural line to this place and connect with the South Haven Mutual.

OWENSBORO, KY.—The Home Telephone Company has commenced work on the construction of an exchange at Ensor. This was necessitated by the increased business.

ECHO, MINN.—The Cokato Telephone Company is erecting a new country line which will be in use this winter.

HARDWICK, MINN.—A large addition is being built to the Enterprise telephone line west from here, and will run to Sherman, S. D.

MANKATO, MINN.—The Citizens' Telephone Company is building two additional lines in the Rapidan District.

KANSAS CITY, MO.—A meeting was held this week at the offices of the Home Telephone Co., of this city, to plan for other extensions of Independent toll lines in this part of the country, particularly to the East and Southeast. The following were in attendance: E. L. Barber, Wauson, O., president of the Western Independent Telephone Co.; Lee Benoist, of St. Louis, representing the Commonwealth Security Co.; J. J. Heim, O. C. Snider and Hugh C. Ward, of the Kansas City Home Telephone Co.

ADDISON, N. Y.—It is proposed to extend the Century telephone line to Addison.

BLOOMVILLE, N. Y.—Grant Mosier is constructing a telephone line from this village to Delhi. This line will be continued to Hobart and Oneonta.

KENMON, N. Y.—The Frontier Telephone Company is installing a local telephone exchange.

LONG BOLTON, OHIO.—The Citizens' Telephone Co. is making arrangements to string a wire across the river at this place to give Murrayville telephone connections.

NORTH CREEK, N. J.—The North Creek Telephone Company has extended its lines from that place to Johnsburg, Thurman and Stony Creek. A switch agreement has been made at Chestertown.

EASTON, PA.—The Slate Belt Telephone Co. is making rapid progress in rebuilding its lines.

S. BETHLEHEM, PA.—The Lehigh Valley Railroad Company has decided to equip its line with private telephone service for the exclusive use of officers of the company, located at many places along the big system.

TROY, PA.—The Citizens' Mutual Telephone and Telegrph Company is erecting a line from Tioga to connect at Painter Run with their line running from Mansfield to Elmira, which will give subscribers a service of four counties, Tioga, Bradford, Lycoming and Potter.

WELLSBORO, PA.—The Citizens' Mutual Telephone and Telegraph Company is erecting a line from Tioga to connect at Painter Run with their line running from Mansfield to Elmira. It will be finished in about 30 days.

SUMTER, S. C.—The Sumter Telephone Company has completed a new line to Summerton.

PIERRE, S. D.—The Capital City Telephone Company will install a new Monarch switchboard to take care of increased business.

ALICE, TEXAS.—J. S. Turner, manager of the Alice, Wade City and Corpus Christi Telephone Company, announces that he anticipates the improvement of the system.

WEST POINT, VA.—The Northern Neck Telegraph & Telephone Co. is improving its line, putting down new poles and extending its system.

EAU CLAIRE, WIS.—The Chippewa Telephone Company is building two new extensions to its system, which will greatly aid in its increased business in this city.

TELEPHONE TRAGEDY.

Act I.

Central—Hello! Number, please?

Man—Gimme 189.

(Ten minutes elapse between first and second acts.)

Act II.

Man—Say! Hello, central! (Rings again.)

Central—Hello! Number, please?

Man—Didn't I tell you I wanted 189?

(Five minutes elapse between second and third acts.)

Act III.

Central—Beg pardon. What number was it you wanted, please?

Man—Blankety! Blinkety! I want 189.

Central (sweetly)—They're busy.
